Final Environmental Impact Statement

Land and Resource Management Plan

Wenatchee National Forest

FINAL ENVIRONMENTAL IMPACT STATEMENT
FOR THE
LAND AND RESOURCE MANAGEMENT PLAN

WENATCHEE NATIONAL FOREST

Chelan, Kittitas and Yakima Counties in Washington

February 1990

LEAD AGENCY: USDA, Forest Service

RESPONSIBLE OFFICIAL: John F. Butruille, Regional Forester
Pacific Northwest Region

ABSTRACT

This Final Environmental Impact Statement documents public comments received on the Draft Environmental Impact Statement and Proposed Forest Plan, the changes made in response to those comments, and economic and environmental analysis of the Alternatives. Eleven Alternatives are presented for managing the 2,164,180 acre Wenatchee National Forest. These are: (NC) No Change, a representation of management direction included in the Forest's 1963 and 1968 Timber Management plans, (A/NFMA) Current Direction (No-Action), which continues the management of the Forest according to current plans and policies with levels of outputs and activities updated to reflect the current data base; (B) RPA, which responds to the 1980 Resources Planning Act (RPA) Program, (C) a modification of Alternative A/NFMA to maximize net public benefits and provide a balanced program in response to issues and concerns, (D) emphasizes the production of commodity resources such as timber, livestock forage, and developed recreation, (E) maximizes the protection of amenity values such as unroaded recreation opportunities, scenery, fish and wildlife habitat, (F) emphasizes the protection of unroaded recreation opportunities, scenery, fish and wildlife habitat, (G) offers a combination of commodity and amenity benefits, (H) provides the maximum timber production under the current land allocations, (I) a departure from the base timber sale schedule established under Alternative C; and (J) an alternative developed by timber industry, which emphasizes levels of timber harvest and commodity outputs while providing as much amenity values as possible.

Alternative C is the Forest Service preferred alternative. The selected alternative will become the Forest Plan and will guide management of the Wenatchee National Forest for the next 10 to 15 years.

SUMMARY **OF THE FEIS**

INTRODUCTION

The Final Environmental Impact Statement (FEIS) discusses the eleven alternatives developed in preparation of the Land and Resource Management Plan (Forest Plan) for the Wenatchee National Forest. The environment to be affected and the environmental consequences of implementing each alternative are also discussed. The FEIS and Forest Plan responds to public comments received from review of the 1986 Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Plan and the 1988 Supplement to the DEIS. The Forest Plan would be in effect for 10 to 15 years, unless revised sooner.

This document is a general summary of the entire FEIS. It emphasizes the issues and concerns raised by the public and other local, State, and Federal agencies, regarding the management of the Wenatchee National Forest. The summary will briefly describe the purpose and need for the FEIS, and give a brief description of the alternatives, the affected environment, and the environmental consequences of implementation of any of the alternatives.

PLANNING AREA

The Wenatchee National Forest lies on the east side of the Cascade Mountain Range in Central Washington. It extends about 140 miles from north to south, and an average of 35 miles east to west. The Forest has a net area of 2,164,180 acres (larger than Delaware and Rhode Island combined).

Steep, rugged mountains and heavy snowpacks characterize the western portions of the Forest. In contrast, near desert conditions prevail in the eastern grass and shrub covered foothills and valleys. Between the two extremes are diverse forest and plant communities resulting from the variations in soils, elevation, aspect, temperature, precipitation, and fire influences. The major drainage systems include the Chelan, Entiat, Wenatchee, Upper Yakima, and Naches-Tieton River systems. All flow eastward toward the Columbia River. Principal Forest resources include timber, forage (for wildlife and livestock), recreation, water, and wilderness. Almost two out of every five acres on the Forest (39 percent) are Congressionally-designated wilderness.

PURPOSE AND NEED

The purpose of the Forest Plan is to direct all natural resource management activities on the Forest. Preparation of the Forest Plan is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), plus the associated National Forest System Land and Resource Planning Regulations (36 CFR 219 - Refers to Part 219 of Title 36 of the Code of Federal Regulations dated 9/30/82).

The preparation of an environmental impact statement disclosing a preferred alternative and a broad range of additional alternatives is required by the National Environmental Policy Act of 1969 (NEPA), the Council on Environmental Quality (CEQ), NEPA Regulations (40 CFR 1500), and the implementing regulations of NFMA (36 CFR 219). A FEIS is required because the Forest Plan is a major Federal action with a significant effect on the quality of the human environment. For the purpose of disclosure under NEPA, this FEIS and the accompanying Forest Plan are treated as combined documents.

PLANNING PROCESS

The National Forest Management Act implementing regulations require several planning steps to be used in developing the FEIS and the accompanying Forest Plan. These planning steps are described in Chapter I.

PLANNING ISSUES

An analysis of the issues determined that ten of the 18 issues identified were most important in formulating the various alternatives for the Wenatchee National Forest Plan. However, all 18 of the major issues influence the alternatives to some degree. The ten most important issues (which are stated as Planning Problems in Chapter I and Appendix A of the FEIS) are described as follows.

1. Recreation Use

An issue is the type of recreation use provided by the Forest. Some people want increased opportunities for unroaded, non-motorized recreation outside of designated wilderness while others want increased opportunities for motorized recreation and developed sites. Opinions also differ regarding the use and restrictions of off-road vehicles.

2. Unroaded Lands

The public is strongly divided on a related issue, that being the future management of the remaining roadless areas on the Forest. Some people would like to develop the timber and other commodity potentials of these areas. Others would like these areas to remain roadless and undeveloped. There are also conflicts about what types of recreation opportunities should be provided in roadless areas (motorized or non-motorized).

3. Wild and Scenic River Designation

There has been a strong response to Wild and Scenic River designation of waterways within the Forest. Some believe that all rivers on the Forest should be included in a preliminary administrative recommendation to Congress for consideration under the Wild and Scenic Rivers Act. Others are strongly opposed to the recommendation of rivers or river segments for designation, especially those rivers or river segments that include private lands within the corridors. Some are also concerned with the level of classification proposed for those river segments outside wilderness.

4. Water Quality and Quantity

Another issue is that of water quality and quantity. Topics include the reduction or elimination of water quality degradation, and the management direction needed to maintain or enhance water quality and quantity.

5. Wildlife Habitats

Wildlife habitat and diversity is believed by some people to have received inadequate attention on the Forest. Some are very concerned about the future management of anadromous fish habitat and old growth forest-dependent species, such as the northern spotted owl, pileated woodpecker, and marten. Other people are concerned that management for these wildlife species will seriously reduce the amount of timber available for harvest.

6. Old Growth

An issue of concern to the public is the treatment of old growth. Some believe that all existing old growth on the Forest should be preserved for biological diversity, dependent wildlife species, scenery or esthetic values. Others believe that both existing and potential old growth within designated wilderness is more than enough to meet all future needs.

7. Scenic Resources

The scenic quality of the environment is a concern of most recreation visitors to the Forest. Some would like to see maximum protection of the scenic values. Other people would like to see the Forest managed for wood fiber with few, if any, visual considerations. Still others favor the maintenance of scenic quality only in key travel corridors.

8. Production of Timber

Production of timber on the Forest is a major issue. Some people want increased emphasis on protection or preservation of non-timber resources, such as scenery, wildlife habitat, and water quality. Some want moderate development. Others favor intensive management of commercial timber species, with full development for consumptive uses.

9. Livestock Grazing

An issue is the level of livestock grazing the Forest should provide. Some feel that cattle and sheep cause damage to Forest resources and are not an appropriate use of the land. Others strongly favor grazing as a viable use of available forage and wish to see the use expanded.

10. Cultural Resource Sites

The locating and management of the cultural resource sites on the Forest is another issue. The American Indian community has strong concerns about the preservation of Indian cultural sites and traditional use areas. There are also local community concerns about the protection and interpretation of cultural resource sites.

CHANGES MADE BETWEEN THE DRAFT AND FINAL ENVIRONMENTAL IMPACT STATEMENTS

Several changes were made between the development of the draft and the completion of the FEIS as a response to public comments and internal concerns. These changes are summarized below. A more complete discussion may be found in the introductory pages of each chapter in the FEIS.

1. A new alternative, Alternative J, was added in response to public comment. This alternative was developed by timber industry representatives.
2. In all alternatives, the Mature/Old Growth MR network was revised. The number of Spotted Owl Habitat Areas was increased in response to the Supplement to the Regional Guide EIS. Management of the Spotted Owl Habitat Areas changed from a "managed" to a "dedicated" prescription which does not have a scheduled timber harvest.
3. Alternatives A/NFMA, C, E, F, G, H, and I all have different recommendations for Wild and Scenic River designation, and river segment classifications than were presented in the

draft. Alternatives C, E and F also have the new MP-1 prescription for the Mather Memorial Parkway along Highway 410, on the Naches Ranger District.

4. Alternative C, the preferred alternative, has numerous changes in allocation boundaries as well as the addition of two additional prescriptions: RE-4 Roadless Harvest and EW-3 Roadless Wildlife.

5. A number of changes were also made in the modeling used for the analysis of the alternatives.

AFFECTED ENVIRONMENT

The Wenatchee National Forest is currently managed under several different plans. Examples of these include the Wenatchee Timber Management Plan, the Chelan Unit Management Plan, the Kittitas Land Management Plan, District Multiple Use Plans, and the Alpine Lakes Area Land Management Plan. These plans do not meet the intent of the National Forest Management Act of 1976 nor do they provide sufficient direction to meet current issues and concerns.

The Forest Plan supercedes all previous land management plans prepared for the Forest except the Congressionally mandated Alpine Lakes Area Land Management Plan. However, management direction in the Alpine Lakes Plan is incorporated in the Forest Plan. Upon implementation, all subsequent administrative activities affecting the Forest, including budget proposals, will be consistent with the Forest Plan.

A description of the current condition of each resource and the environment to be affected by implementation of any of the alternatives is as follows:

Recreation Setting

The tremendous diversity of elevation, vegetation, and precipitation on the Wenatchee National Forest results in an equal variety of recreation uses and opportunities. The Forest has been the sixth most heavily visited National Forest in the country for the past several years, with almost five million recreation visitor days (RVD's) of use in 1986.

There are 244 developed recreation sites on the Forest including campgrounds, boating sites, recreation residence tracts, and ski areas. Campgrounds alone account for over a million RVD's of use per year. Theoretically, the present inventory of developed sites is more than adequate to meet the projected demand. However, developed sites in specific areas are overcrowded now and nearly all sites are used to near capacity on summer weekends.

Dispersed recreation refers to those recreation activities that occur outside of developed sites. It includes such activities as camping in undeveloped areas, hiking, off-road vehicle use, fishing, boating, hunting, river floating, horseback riding, mountain climbing, snowmobiling, cross-country skiing, firewood gathering, berry collecting, and driving for pleasure. Dispersed use (outside of wilderness) totaled over 2.2 million RVD's in 1986.

There are currently 2,463 miles of trail on the Forest with approximately 48 percent of them in wilderness. The Forest Service is presently working with users to develop four-wheel-drive trails, trail bike routes, and cross-country ski and snowmobile trails.

Roadless Areas

Inventoried roadless areas consisted of 556,272 acres as of April, 1985. With the passage of the Washington State Wilderness Act of 1984, these areas are not required to be managed for the purpose of protecting their suitability for wilderness classification. A full range of multiple use activities is currently taking place and will continue throughout the time that the Forest Plan is

being developed to the time of implementation. This will result in some change in the roadless status during that period of time.

Wild, Scenic, and Recreational Rivers

The Wild and Scenic Rivers Act of 1968, as amended, established a means of providing Federal protection for certain of the free-flowing rivers that remain in the United States. To be eligible for inclusion in the National Wild and Scenic River System, rivers were required to meet certain criteria set forth in Section 2(b) of the Act. In order to identify potential rivers meeting these criteria, the National Park Service completed a Nationwide Rivers Inventory (NRI) in 1982. Among the rivers listed in the NRI were the Chiwawa, White, Wenatchee and Yakima Rivers.

Present management of these river corridors is guided by the Forest Service Handbook. This direction specifies that management and development of the identified river and its corridor should provide for the protection of its free-flowing characteristics, to the extent authorized under law, as well as those outstandingly remarkable values which contribute to its eligibility.

Subsequent to publication of the NRI, some 30 additional rivers and creeks on the Wenatchee National Forest were identified for potential designation through in-Service study and public input. As a result, these rivers are being assessed for eligibility, and suitability where appropriate, for inclusion in the Wild and Scenic River System.

Cultural Resources

The cultural resource base of the Wenatchee National Forest includes a diverse and unusually rich range of historic and prehistoric artifacts and sites. These include: 1) historic cabins, trails, mines, ditches, railroad grades, emigrant trails, original highway grades, mulls, and homesteads; 2) historic Forest Service structures including guard stations, lookout towers, corrals, camps, administrative centers, and Depression-era campgrounds and buildings; and 3) prehistoric campsites, villages, graves, quarries, pictographs, workshops, trails, rock shelters, and religious sites.

In accordance with the National Historic Preservation Act of 1966, the National Environmental Policy Act of 1969, Executive Order 11593, the National Historic Preservation Act Amendment of 1980, as well as a series of implementing regulations and policy direction, the Forest has undertaken a program to identify, evaluate, preserve, and protect the cultural resources. A cultural resource overview, pulling together most of the recorded information relating to the prehistoric and ethnographic uses of the Forest has been completed and will be available for review at the Forest Supervisor's Office.

The relationship and interaction between American Indian rights and uses of the Forest and other Forest management activities is complex. Rights reserved to the Indians by the Yakima Treaty will affect Forest management activities, particularly those actions that could impact water quality and anadromous fish habitat. Other Indian-related issues that may influence Forest programs are protection of wildlife resource values and ancestral sites; recognition of social/cultural/religious values with respect to the landscape and resources of the Forest; and assurance of access to traditional resource collection areas. Litigation with respect to Indian rights is ongoing in many areas of the United States and may result in future changes in management practices on the Forest.

Scenery

The Wenatchee National Forest is well known for its outstanding mountain, valley, and lakeshore scenery. The Cascade Mountain landscapes are distinctive in beauty and nature, with sweeping vistas covering a variety of topography, ecotypes, and lifeforms. Natural-appearing environments exist on much of the Forest, even where intensive commodity management is occurring. Approximately 63 percent of the Forest, including wilderness, is in a natural-appearing condition.

Public demand for scenic quality is increasing and is expected to continue to increase over the next decade. The concerns for visual quality are highest along the major state highways that cross the Forest, along roads accessing wilderness, and in areas near recreation sites and communities.

Wilderness

Wildernesses occupy 39 percent of the area on the Wenatchee National Forest. They span a multitude of environments and elevations ranging from low, open, grassy slopes to timber stands of all ages and varied species; from subalpine and alpine areas to the rugged, rocky peaks of the Cascade Range.

Glacier Peak, Alpine Lakes, Henry M. Jackson, and Norse Peak Wildernesses extend across the Cascade Crest into the Mt. Baker-Snoqualmie National Forest while the William O. Douglas and Goat Rocks Wildernesses extend into the Gifford Pinchot National Forest. In the north, the Wenatchee and Okanogan National Forests share the Lake Chelan-Sawtooth Wilderness. Managers of neighboring Forests work together to develop uniform direction to be used by each Forest for the management of these shared wildernesses.

Wildlife

The Wenatchee National Forest provides year-round or seasonal habitat for an estimated 394 species of fish and wildlife. Of the 394 species, there are 13 amphibian, 18 reptile, 273 bird, and 90 mammal species. About 250 of these species reside year-round on the Forest.

The diversity of vegetation types and plant successional stages on the Forest provide a variety of wildlife habitats; some of these habitats are referred to as unique or special habitats. These include habitats such as old growth forests, riparian zones, snags, down, woody material, cliff and rim environments, caves and burrows, and talus slopes.

One Federally-listed endangered species, the peregrine falcon, is a known resident of the Forest, but no active nests have been located. The bald eagle is listed as threatened and several other species are considered sensitive.

Fisheries

Fish and the aquatic resources on the Wenatchee National Forest provide major recreational and aesthetic assets. Commercial and sport fisheries depend upon the Forest ecosystem to provide spawning and rearing habitat as well as a quality source of fresh water for downstream fisheries. Maintenance of this fish habitat and water quality is a strong concern of the public, State and Federal natural resource agencies, and representatives of the Colville and Yakima Indian Nations.

The aquatic habitats support 15 species of coldwater game fish and 3 species of warmwater game fish. Five species of coldwater anadromous and resident salmonoid species account for 95 percent of the angling. Four percent of the fishing is distributed among the other cold water species, while less than one percent is spent in warm water fishing.

Vegetation: Trees

Conifer forest ecotypes occupy approximately 69 percent of the Forest. Elevation, soil types, precipitation, and aspect combine to create a wide variety of ecological vegetative types. For simplicity, these can be combined into the three habitats of dry forest, wet forest, and sub-alpine parkland and mountain meadows.

Of the 2,164,180 acres on the Forest, 791,899 (37 percent) are tentatively suitable for timber production. These lands are capable of growing industrial wood and are suitable for timber management activities. During the period of 1977 to 1986, the average annual volume offered for sale was 192 million (MM) board feet, the average actually sold was 172 MM board feet, and the average actually cut each year was 162 MM board feet. The best estimate for the future is that demand will continue to be close to the average harvest level of the last few years.

Vegetation: Old Growth

It is estimated that there are 319,000 acres of old growth on the Forest, of which 148,000 acres are in wilderness. These latter acres occur in scattered parcels ranging in size from five acres to

several thousand acres. Low elevation areas that have been readily accessible to timber harvest have few old growth stands. Consequently, the amount of old growth has been in decline for many years.

Old growth is preserved for biological diversity, wildlife and plant habitat, and for aesthetic reasons. For the next decade, the majority of old growth will occur in wilderness, unroaded areas and in the areas protected for the old growth-dependent management indicator species (pileated woodpecker, pine marten and especially northern spotted owl).

Vegetation: Forage

The vegetative types within the Forest environment have evolved through the natural interactions of grazing animals and wildfire occurrence. Fire has removed or thinned the tree vegetation, while large grazing animals have used and modified the resulting forage resource. This interaction has provided a wide diversity of vegetation and wildlife. Grazing of vegetation by large wildlife species, such as elk, modifies the forage and retains some types in successional stages beneficial to use by deer, mountain sheep, and many small game and non-game species.

Forage for grazing animals is present throughout the Wenatchee National Forest as a component of all vegetative types. Supply is expected to exceed permitted use through all five decades, which will allow resolution of resource conflicts and also offer an opportunity to utilize livestock to enhance other resource objectives.

Vegetation: Unique Ecosystems

Unique ecosystems are areas that support or contain unique vegetative, ecologic or geologic attributes worthy of protection. The one existing area on the Forest is the Tumwater Botanical Area, which is to be managed in a near natural condition to protect the Lewisia tweedyi plant that grows there. Because the objective of the botanical area is to maintain a natural ecosystem, activities such as timber harvest, heavy recreation use, prescribed fire and grazing are prohibited.

Vegetation: Sensitive Plants

The Forest has a large variety of unique plant species. These species represent habitats and plant communities which have developed as a result of various geological processes. There are no known Federally-listed threatened or endangered plant species on the Forest, but there are 34 plant species that are on the Region 6 sensitive plant list. Of the 34, four are candidates for Federal listing and the remaining 30 are listed by the State of Washington. The extent of the populations of these species in the Forest is unknown.

Vegetation: Research Natural Areas

Research Natural Areas (RNA's) are part of a Federal system of such tracts established for nonmanipulative research and educational purposes. Each RNA is a site where some features are preserved for scientific purposes and natural processes are allowed to dominate. There are two established RNA's on the Forest: Meeks Table RNA in the Wilham O. Douglas Wilderness, and the Thompson Clover RNA located in Swakane Canyon.

The Research Natural Area Committee for the Pacific Northwest has formally proposed two other RNA's: Eldorado Creek in the Teanaway drainage and Fish Lake Bog at the west end of Fish Lake. There are also four additional areas that are currently recommended as candidate RNA's on the Forest.

Water

The Wenatchee National Forest manages mountain watersheds to produce clean water for individual and community water sources; for maintaining a viable fishery; to provide agricultural irrigation, and to provide for timber production, scenery, recreation, grazing, and wildlife. Annual runoff on the Forest is approximately 4 5 million acre-feet from 25 subwatersheds. Nearly 95 percent of the water used for irrigation and domestic water systems in Chelan, Kittitas, and Yakima Counties is provided from Forest lands.

Soil

Within the boundaries of the Forest are more than 200 different kinds of soils. Part of the reason for this high number are the more than 30 major geologic formations; elevations that range from 750 to over 9,000 feet; precipitation that ranges from 10 to over 120 inches per year; and the great variation in topography. Its variety is further complicated by the effects of transported materials such as glacial till, glacial outwash, alluvium, and volcanic ash and pumice.

A soil inventory for Forest lands within Kittitas County was completed in 1981. The Chelan County survey was completed in 1989 with Yakima County to be started in 1989. The Forest has also made an inventory of areas that have been significantly damaged and are presently eroded or causing management problems. Since 1980, the Forest has identified 143 inventoried sites.

Air

Since the passage of the Clean Air Act in 1970, the Wenatchee National Forest has been involved with the management of the air resource. Rapid development of the program has occurred during the last five years and this trend towards more intensive air resource management is expected to continue.

Within the Forest, prescribed fire and wildfire are the largest contributors to the temporary degradation of air quality (primarily causing reduced visibility from smoke or haze), but the management of all vegetation is known to be important to the maintenance of the chemical components of the atmosphere. The quality of the air resource on the Wenatchee National Forest can normally be described as "good" in comparison with the more populated areas which surround the Forest.

Minerals

The Forest has a long history of mining, with numerous claims having been located in the 1870's and maintained since then. Excluding the Holden Mine, the Forest has a modest past production record. More recently, following the Cannon gold mine discovery in 1983, more than 7,000 mining claims were located in the surrounding area. However, present mineral activity on Forest lands is relatively minor in scope.

In approximate decreasing order of importance, the Forest contains potentially significant occurrences of copper, gold, molybdenum, silver, lead, zinc, tungsten, iron, chromium, nickel, mercury, and manganese. Based upon available data, oil and gas resources are not presently known to exist on the Forest in commercial quantities but only limited geophysical surveys have been completed. Nevertheless, there are a total of 22 oil and gas leases issued covering 64,113 acres.

Roads

Since the 1940's, the majority of Forest road construction has been in support of timber management activities. Currently 33 percent of the total Forest and 53 percent of the non-wilderness acres are considered roaded. In the roaded areas, there are approximately 3.75 miles of road for each square mile of land.

In 1988, there were an estimated 5,110 miles of Forest Service roads on the Forest. About 18 percent of this total are classified as arterial and collector roads. Forest arterials and collectors access large or popular land areas and usually connect with State and County roads to form an integrated network of primary and secondary travel routes. The system is 98 percent complete.

Fire

Fire has played an important role in the ecology of the Wenatchee National Forest and is responsible for much of the diversity of vegetation that exists today. Wildfires ranging from 100 to several thousand acres in size have occurred in the northeast portion of the Forest every 10-20 years. The numbers of fires in the southerly portions of the Forest are similar but acreages are much smaller. New policies call for fighting fire in the most cost-efficient manner.

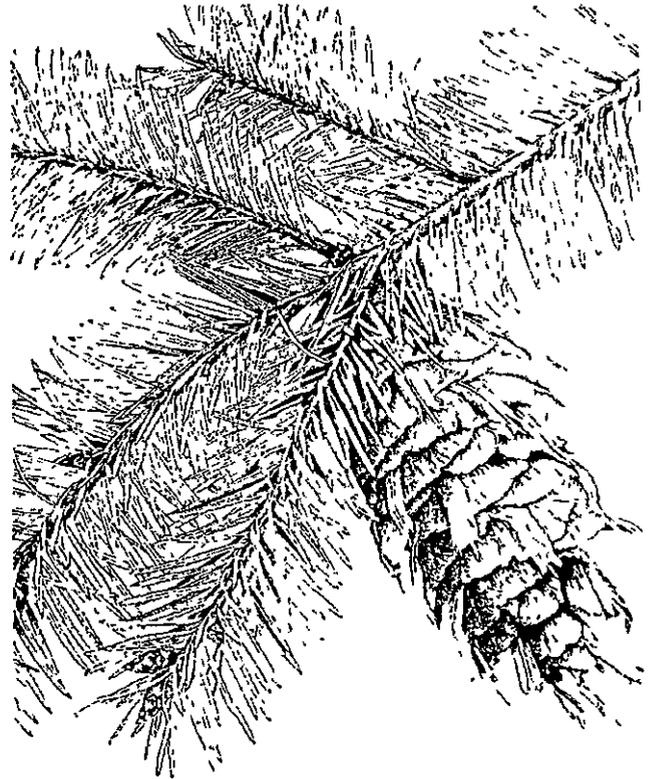

Currently, the Forest is using prescribed fire to treat an average of 6,354 acres annually for the enhancement of resources such as wildlife habitat, scenic diversity, recreation area management, site preparation for reforestation, and the reduction of fire hazards.

Social/Economic

Many of the residents of the communities adjacent to the Forest derive their livelihood from Forest-related activities, and many participate in a wide variety of Forest-oriented recreation. The balance of commodity and amenity resource uses are important components in their lives. In addition, Forest management affects out-of-area recreationists who live in metropolitan areas of Washington State. These people are most concerned with the quality of the recreation setting and scenery, wilderness, road access and hunting opportunities.

ALTERNATIVES INCLUDING THE PROPOSED ACTION

Eleven alternatives were developed encompassing a full range of resource outputs and environmental effects. Each alternative presents a combination of management areas where sets of management practices and activity scheduling occur. Some management areas emphasize protection of wildlife habitat and naturally-occurring ecosystems, while others emphasize sustained timber yields or various types of recreation opportunities. Each alternative distributes Forest lands to management areas in different ways. These are listed by acreage in Table S-1.

Each alternative is comprised of land uses, management practices, and activity schedules which result in a unique combination of resource outputs, land uses and environmental conditions. The Preferred Alternative is that alternative which is selected from all those formulated as the one which best maximizes the net public benefits. The actual selection of the Preferred Alternative is done by the Regional Forester.

For the Wenatchee Final Environmental Impact Statement, the Preferred Alternative is Alternative C.

The major reason that alternatives differ is that each responds to issues, concerns, and resource opportunities identified for this Forest in different ways. The following narrative and subsequent Table S-2 summarize these differences between alternatives.

The No Change Alternative (Alternative NC)

The No Change Alternative was developed in response to decisions made regarding appeal number 1588 brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by Regional Forester James F. Torrence to "require inclusion of minimum management requirements (MR's) in the Current Direction Alternative for each Forest Plan." In response to this, a No Change Alternative was developed to represent the existing Timber Management plans. Consequently, it does not comply with all provisions of the National Forest Management Act of 1976 (NFMA) and regulations (36 CFR 219) promulgated by the Secretary of Agriculture to implement NFMA.

Alternative NC displays the objectives, outputs, and effects of the Wenatchee National Forest's Timber Management (TM) Plans so that they can be compared with the other alternatives. However, since the development of the TM plans, new inventories, assumptions about resource interrelationships, and new methods for predicting timber growth and yields have been developed. Therefore, a reviewer should be aware that information provided for Alternative NC is frequently based on outdated inventories and yield tables and is not always comparable to information provided for the other alternatives.

Alternative A/NFMA

This is the No Action Alternative. It was formulated to maintain the current management direction for the Forest. Sources of that direction were the Alpine Lakes Area Management Plan, the Chelan and Kittitas Unit Plans, and the Ranger District multiple use plans. Alternative A/NFMA portrays how these plans would influence the flow of goods and services over the life of this plan (10-15 years) based upon the use of current National Forest Management Act of 1976 (NFMA) planning data. It also approximates the current budget. This alternative meets all the management requirements of NFMA, including protection of habitat for wildlife dependent upon old growth and mature habitat types.

One of the features of this alternative is that it contains significantly fewer acres of EW-1 (Key Big Game Habitat) than any other alternative except the No Change Alternative. The reason for this is that most of the existing plans did not contain specific allocations for key big game habitat.

Alternative B

This alternative is an attempt to meet the 1980 Resources Planning Act (RPA) program which has been assigned to the Forest through the Regional Guide.

The 1980 RPA timber target strongly influenced the approach. This alternative uses the Alternative D land allocations. It portrays the Forest's maximum timber producing capability while considering other resource needs. This alternative would result in the greatest amount of development of the Forest.

A feature of this alternative and Alternative D is the higher allocation to General Forest (GF) and a corresponding decrease in the unroaded and scenic travel allocations. The major difference between this alternative and Alternative D is that in Alternative B more intensive timber management will be practiced on the GF land allocation, with higher yields and higher annual sale quantities resulting.

Alternative C

This alternative was developed by adjusting the current direction (Alternative A/NFMA) to a land allocation which would maximize net public benefits and which would provide a balanced program in response to the issues and concerns. The purpose of Alternative C is to respond to concerns for protecting wildlife and other amenity resources, and provide a variety of recreation opportunities while managing the Forest for commodity outputs. This was accomplished by modifying existing plans and practices to respond to public concerns received during issue identification early in the planning process. Further modification of this alternative has been done to respond to comments received through the public response to the Draft EIS.

Another way Alternative C differs from Alternative A/NFMA is that it allocates many more acres to key big game range, and increases the acreage allocated to roadless management.

Alternative D

This alternative emphasizes the production of resources such as timber, range, forage, developed recreation, minerals, and other resources which have the potential to return revenue to the Federal Treasury and local counties. Management of other resources is at economically and environmentally feasible levels consistent with the emphasis on market-oriented outputs.

A feature of this alternative and Alternative B is the higher allocation to General Forest (GF) and a corresponding decrease in the unroaded and scenic travel allocations. The major difference between this alternative and Alternative B is the economic emphasis. This results in less intensive timber management on the GF land allocation, and a lower annual sale quantity with an increased present net value compared to Alternative B.

Alternative E

This alternative allocates all currently roadless areas outside of the existing wilderness and the Alpine Lakes Management Area to a management prescription which will maintain their roadless status. It also emphasizes the protection of natural scenery, fish and wildlife habitat, and other amenity values. Management of other resources would be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

Alternative F

This alternative emphasizes unroaded recreation, protection of natural scenery, protection of fish and wildlife habitat, and other amenity values. It allocates approximately 80 percent of the currently roadless area outside of the existing wilderness and Alpine Lakes Management Area to roadless management prescriptions with heavy emphasis on non-motorized recreation. Management of other resources would be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

The Forest was assisted in the development of this alternative by a coalition of environmental groups from throughout the state.

Alternative G

This alternative is an attempt to balance the land allocations between amenity values and commodity production emphasis. The goal is to intensify commodity production on the lands not allocated to roadless management. Of the current roadless areas outside of existing wilderness and the Alpine Lakes Management Area which are suitable for timber production, approximately half was allocated to roadless management with a heavy emphasis toward motorized recreation, and the remainder was allocated to commodity production. On the lands allocated to timber production, a trade-off was reached between maximizing present net value and maximizing timber production.

The Forest was assisted in the development of portions of this alternative by representatives of off-road vehicle users groups from throughout the State.

Alternative H

This alternative portrays the maximum timber producing capability of the Forest under the present land allocations of existing management direction. It has the same land allocations as Alternative A/NFMA. The major difference between this alternative and Alternative A/NFMA is that more intensive timber management will be practiced on the General Forest land allocation, which will result in higher yields and higher annual sale quantities with a corresponding decrease in present net value.

Alternative I

Alternative I is a departure from the base sale schedule established under Alternative C, the preferred alternative. It has the same land allocations as Alternative C. The timber harvest schedule for Alternative C is based upon nondeclining flow, never exceeding long-term sustained yield. Alternative I has the same long-term sustained yield capacity as Alternative C but deviates from nondeclining flow. The level of timber harvest in the first decade approximates the average annual sell volume for fiscal years 1975 through 1984 under the current Timber Management Plan. The level of timber harvest gradually declines in the second and third decades, equaling that of Alternative C in the fourth decade. This would allow local industry to phase into a lower level of timber harvest more gradually than in Alternative C. The effects on other resources could be greater in the early decades due to the accelerated rate of timber harvest under the departure.

Alternative J

This alternative was developed by representatives of timber industry after release of the Wenatchee DEIS. They referred to it during the public input process as the "Essential Alternative". The goal of this alternative is to maintain timber harvest and other commodity outputs at their highest levels, while providing as much of the amenity outputs as possible without dropping ASQ below the level of the existing timber management plans.

Alternative J has the highest acreage of GF land allocation of any of the alternatives with correspondingly lower roadless and scenic travel allocations. There are no scenic travel retention allocations outside of the Alpine Lakes Management Area, and there is only a limited partial retention allocation along the Mather Memorial Parkway, the Entiat River, Lake Wenatchee and a part of the Chiwawa River road.

SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS

The following table summarizes the outputs of the alternatives as they relate to the planning problems. On this one table, the reader can quickly compare the major quantifiable results of each alternative. The qualitative results can be found in Chapter II of the FEIS, Table II-3b.

TABLE S-2

1/ Alternatives are ranked in order of decreasing present net value (except for NC which does not have a PNv computed) All resource outputs cannot be reasonably estimated for Alternative NC because the TM plans were based on different yield tables and resource relationships.

2/ Alternative J has different standards and guidelines for key wildlife habitat areas and Retention/Partial Retention areas than the other alternatives Refer to Appendix D for more information

ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES

Implementation of any alternative, including the preferred alternative, would affect the environment and resources of the Forest and its surroundings. Both short-term effects, meaning effects which could occur over the first few decades, and long term effects, which could be anticipated in decades beyond, were considered. Direct and indirect effects were analyzed. Quantitative and qualitative outputs and effects are summarized in Tables II-3a and II-3b in Chapter II of the FEIS.

The following section summarizes the consequences the different alternatives would have on the Forest and its surroundings. The discussion is organized by environmental component.

Recreation Setting

The ability of the Forest to supply a spectrum of recreation opportunities varies significantly among alternatives. Some, such as Alternatives E and F place more emphasis on primitive and semi-primitive (undeveloped) recreation opportunities. Other alternatives place more emphasis on developed, or roaded, dispersed recreation in natural-appearing or modified environmental settings.

Alternatives NC, A/NFMA, E, F and H emphasize developed recreation at current levels. Selected sites would be brought up to fee standards, with the remainder maintained with very few improvements. In all five of these alternatives, some overcrowding and conflicts could occur at the more popular sites. In contrast, Alternatives B, C, D, G, I and J would provide a high level of developed site capacity, with few impacts resulting to the recreation setting as a result of visitor use.

Dispersed recreation opportunities and the quality of the recreation setting in dispersed recreation areas is of utmost importance to visitors to the Forest. It is in dispersed areas that most of the recreation visitor use occurs and where a wide range of activities are conducted. The capacity for roaded, dispersed recreation greatly exceeds the demand in all alternatives. Impacts to the social setting (congestion, noise, dust, law enforcement problems) will only occur in highly popular areas during peak use times.

Unroaded Areas

Roadless areas would be managed differently under each alternative, according to the objectives of the alternative. Roadless areas allocated to development of timber and forage resources would change in character. Over time, they would no longer offer opportunities for semiprimitive, nonmotorized recreation, nor would they qualify for wilderness designation. The quality and quantity of old growth habitat and scenic quality in these areas would also decline. On the other hand, timber management opportunities and potential volumes would be foregone in roadless areas allocated to provide unroaded recreation opportunities (RE-2a, RE-2b and RE-3). Table S-3 displays the number of acres being retained in the unroaded setting by alternative.

TABLE S-3
PERCENTAGE OF INVENTORIED ROADLESS AREAS REMAINING ROADLESS

1/ Net National Forest area as of April 1985

2/ There are 1,632 acres of an Experimental Forest which fall within the boundaries of this roadless area. They will be managed for research purposes and therefore are subject to access by road

3/ These areas lie within the Alpine Lakes Management Plan Area. The management of these areas has been directed by that plan which is currently being implemented. The management will not be changed by the Forest Plan and therefore the current management allocations for these areas will remain unchanged through all alternatives. These allocations include both roaded and unroaded management activities

The explanations given under footnotes 2/ and 3/ are given to indicate why 100 percent of the combined inventoried roadless area is not allocated to unroaded management under Alternative E. Because of the presence of bare rock, talus slopes, ice, unproductive grounds, and isolated pockets of productive lands, 100 percent of the roadless areas also cannot be allocated to full timber production and roaded development.

Wild, Scenic, and Recreational Rivers

Of the 33 rivers and river segments on the Forest considered for potential inclusion in the Wild and Scenic River System, ten were determined to meet the eligibility criteria. Recommendations for these ten vary by alternative.

In Alternatives E and F, all ten rivers are recommended for designation at their highest potential classification. The values and characteristics which contribute to the eligibility of these waterways would be fully protected under these two alternatives. Alternatives C and I recommend nine of the ten eligible rivers (only the Little Wenatchee is excluded), but with some segments proposed at less than their highest potential classification. Areas with substantial private holdings are generally recommended as Recreational in these latter alternatives, so as to accommodate local governmental land use objectives.

Alternative H is similar to Alternative C in that portions of nine of the ten eligible rivers are recommended for designation. However, those segments with substantial private holdings are not proposed for inclusion in the Wild and Scenic River System (the lowest segments of the Icicle, White, Napeequa, and Chiwawa Rivers, the lower two segments of the Cle Elum River, and the upper segment of the Wenatchee River). These corridor segments would be managed instead for Scenic Travel, with a visual quality objective of Retention. Most of the river values would be protected in Alternative H, but there could be a modification or loss of the free-flowing character of those segments that are not included in the National System.

The White, Chiwawa and Wenatchee Rivers, which were identified in the Nationwide Rivers Inventory, are the only rivers recommended for inclusion in Alternatives A/NFMA and G. Designation of some segments of these rivers is proposed at less than their highest potential classification, but in each case, the outstandingly remarkable values would be protected.

In contrast, none of the eligible rivers are proposed for inclusion in the National System in Alternatives NC, B, D and J. In these alternatives, the river corridors would be subject to a full range of management activities, with the potential for substantial modification of the visual landscape.

Cultural Resources

In addition to the Forest-wide Standards and Guidelines, the SI-2 management prescription will offer protection of significant cultural resources. However, the management area allocations surrounding the cultural resources do change by alternative. It is assumed that these allocations will affect the overall environmental setting surrounding the cultural resources and may impact currently unidentified subsurface materials. The greater the number of known or potential cultural sites that fall within management areas that may create a high level of modification, the greater is the risk of adverse impacts. In general, those alternatives with higher timber harvest and other developmental activities have a higher potential of adverse impacts.

Alternatives E, F and G overall involve moderate levels of modification to the landscape. The average proportion of known cultural sites and potential or reported cultural use areas that occur within the high impact management allocation areas is relatively low (about 30%). Under Alternatives A/NFMA, C, H and I, approximately 40% of the known and potential cultural resources occur within management area allocations that may have a high level of impact. Visual settings around some significant sites might experience modification apparent to the viewer. Alternatives NC, B, D and J have considerable potential for affecting cultural resources. Generally, 60% of all known cultural sites and potential or reported use areas occur within possible high impact management area allocations. These latter alternatives would require a substantial number of mitigation and protection measures.

Scenery

Scenic quality is affected by the nature of the land allocations proposed in each of the alternatives. The amenity-oriented alternatives will have a greater number of acres allocated to prescriptions that would provide for higher scenic quality and a more natural-appearing landscape. Alternatives E, F and G would emphasize visual quality. Most of the viewsheds would be managed in a natural to slightly altered condition.

Conversely, the commodity-oriented alternatives have higher levels of timber harvest and allocate more acres to prescriptions that will result in a more pronounced modification of the landscape. In Alternatives NC, B, D and J, the major viewsheds and most of the commercial forest lands would be heavily altered. In Alternative J, no viewsheds would be allocated to scenic management.

In the mid-range are Alternatives A/NFMA, C, H and I, which would protect or enhance many of the scenic areas on the Forest, although some viewsheds would not retain their natural-appearing character. In addition, Alternative I would produce greater alteration of the landscape in the first decade due to the increased harvest of timber during that period.

Wilderness

The management of wilderness does not vary by alternative. However, the type and intensity of resource management adjacent to the wilderness, and the type and degree of access afforded would affect the character of the wilderness. This, in turn, could affect both solitude and the overall quality of the recreation experience.

Timber harvest and associated road building activities adjacent to wilderness would affect the scenic quality of views from within the wilderness. The noise and visible evidence of human activity could also disturb the quality of the wilderness experience for visitors. Decreases in other recreation settings on the Forest could displace use to the wilderness, requiring an increase in managerial controls to minimize the impacts of the increased use.

Table S-4 indicates the relationship of unroaded and roaded recreation setting allocations adjacent to each wilderness boundary for each alternative. It also indicates the approximate amount of the unroaded setting that is motorized and non-motorized.

1/ As water is not "allocated," the boundaries adjacent to Lake Chelan are not included. Lake Chelan does have motorized boat traffic.

Wildlife

Each alternative would have effects on environmental components that influence habitat, such as trees, forage, riparian areas, fire, and roads. Changes in wildlife habitat produce changes in the diversity, abundance and distribution of wildlife species. The nature of the effect will depend upon the habitat requirements of the particular species. Habitat for threatened, endangered, and sensitive species would be protected in all alternatives. Habitat for management indicator species (MIS) would also be provided under every alternative except NC through the management requirements (MR's).

Mule deer, Rocky Mountain elk and mountain goats are the MIS for big game habitat. These are affected by alterations in the distribution, arrangement and amount of cover and forage, by road use and by range improvements and forage utilization by livestock. Alternatives E and F would have the least impact on big game due to the high level of unroaded, non-motorized land allocations, the smaller allocations to General Forest, and the high allocation to prescriptions that maintain or improve key big game habitats on both summer and winter ranges. Alternatives NC, B, D and J, on the other hand, would have a greater impact due to the emphasis on roaded recreation, the high allocations to General Forest and intensive range management, and in all but J, the very small or lack of allocation to the key big game prescriptions. Alternatives A/NFMA, C, G, H and I would vary in their effects with respect to recreation, timber, range management and key big game prescriptions, but the overall impact would be a moderate one.

All alternatives have standards for snag management that would meet or exceed that needed to maintain minimum viability levels of the primary cavity excavators. However, Alternatives E, F and G would have the least impact on primary cavity excavator habitat due to the lower timber harvest levels. Alternatives A/NFMA, C, D, H and I would have a moderate impact, and NC, B and J, with their heavy emphasis on timber production, would have the highest risk of impact.

The MIS for mature and old growth habitats are the northern spotted owl, pileated woodpecker, pine marten, and northern three-toed woodpecker. Two habitat factors can limit the populations of these species: the amount of suitable habitat in a given area, and the distribution between suitable habitat areas. Alternatives E, F and G would provide the greatest amount of mature and old growth habitat and have the least number of acres allocated to General Forest. The effects of these alternatives would be small. Alternatives A/NFMA, B, C, D, H, I and J would have a moderate effect on the distribution and abundance of mature and old growth habitats. Alternative NC would have the greatest effect, and in fact could threaten the viability of some species due to a decrease in the distribution and abundance of suitable habitats.

The MIS for riparian habitats are beaver and ruffed grouse, which represent some 260 species that utilize riparian habitats. Although these habitats make up less than one percent of the Forest, wildlife use of riparian ecosystems is much greater than that of adjacent areas. The Riparian-Aquatic Habitat Protection Zone (EW-2) prescription was developed by the Forest to ensure that riparian-dependent resources would be adequately protected in each alternative except NC. Alternative NC would follow current direction to give preferential consideration to riparian-dependent resources where resource management conflicts arise, but this direction is not as protective of the riparian dependent resources as the direction provided in the EW-2 prescription. Alternatives A/NFMA, B, C, D, E, F, G, H, I and J would either protect the riparian habitats under the EW-2 allocation or through other, even more restrictive allocations. However, Alternative C specifies more road closures and therefore, would have less of an impact on the riparian habitats.

On the Forest, the proposed, threatened, endangered and sensitive species include the bald eagle, peregrine falcon, grizzly bear, gray wolf, northern spotted owl, bighorn sheep, Townsend's big-eared bat, Canadian lynx, California wolverine, ferruginous hawk, Swainson's Hawk, and the long-billed curlew. The objectives for the management of these animals are the recovery of Federally-listed species and the assurance that sensitive species

will not become listed. Although these have varying management requirements, overall the highest impacts to these species occur in alternatives with the greatest number of acres allocated to General Forest and roaded, recreation allocations. Alternatives E, F and G would have the least effect due to the allocation of a large number of acres to unroaded, non-motorized prescriptions, and the fact that these alternatives have the fewest acres in General Forest. Alternatives A/NFMA, C, H and I would have a moderate impact, and Alternatives NC, B, D and J, with their emphasis on General Forest and developed recreation, would have the highest potential of affecting the habitats.

Fisheries

The fish habitat management objective for the Wenatchee National Forest is to at least maintain current habitat conditions, and show improving trends in habitat capability over time for both anadromous and resident trout species. Fish habitat capability and production are expected to increase under all alternatives except NC, due to habitat improvement projects, implementation of Best Management Practices, and the Forest Standards and Guidelines. Long term fish habitat capability may decrease under Alternative NC.

In terms of risk of impacts to fish habitat, however, those alternatives with greater timber harvest and resource development carry relatively more potential for effects. Alternatives B, D and J have the highest level of timber harvest and other resource development. Although these alternatives have a high level of funding directed to habitat improvement, there is a greater likelihood that these funds will be needed to mitigate resource management activities. On the other hand, Alternatives E and F provide the greatest potential benefit to fish habitat since they allocate the most dollars to habitat improvement, and have the least resource development. Alternatives A/NFMA, C, G, H and I have a relatively moderate risk, with C and I providing a substantial level of funding to habitat improvement.

Vegetation: Trees

All alternatives will continue to manipulate trees and other vegetation through timber sales, stand improvement, domestic livestock use, and prescribed fire. The difference between alternatives is in the amount of area allocated to timber harvest activities and in the levels of intensity of management.

Under Alternative A/NFMA, timber harvest activities would occur on 75 percent of the lands on the Forest suitable for timber management. Approximately two percent of the suitable lands would be managed at the highest intensity (GF-1) level (see Chapter IV of the FEIS for a definition of the intensity levels), with 29 percent managed at the low intensity (GF-4) level. Among the Special Prescription (SP) variations, Alternative A/NFMA has the largest amount of any of the alternatives managed under SP-3 for partial retention of scenery along travel corridors. Precommercial thinning is planned on overstocked acres within scenic travel corridors under all alternatives. This will increase tree vigor and reduce potential damage from insects such as mountain pine beetles.

In Alternative B, timber harvest would occur on 86 percent of the lands on the Forest suitable for timber management. Approximately 32 percent will be managed at the highest intensity (GF-1) level, with 19 percent of the suitable lands managed at the moderate intensity (GF-3) level. Alternative B will manage about half as many acres under SP-3 for partial retention of scenery along travel corridors, as in Alternative A/NFMA.

Alternative C would have harvest activities occurring on 73 percent of the lands suitable for timber management. Less than 3 percent of the suitable lands would be managed at the highest intensity (GF-1) level, with 14 percent of suitable land under this alternative managed at the GF-4 intensity and almost an equal amount managed under GF-3. This latter prescription is the most silviculturally and economically sound prescription for many stand types.

Alternative D has the same General Forest allocations as Alternative B. However, within the "General Forest" area a reduction in investment level would result in entirely different stands.

Under this alternative, only three percent of the suitable lands are managed at the highest intensity (GF-1) level. In contrast, 44 percent of the suitable lands would be managed at the low intensity (GF-4) level.

For Alternative E, 52 percent of the suitable lands on the Forest will have timber harvest activities occurring on them. This is the only alternative that proposes no acres for the highest intensity General Forest allocation, GF-1. Most of the timber management under this alternative would be aimed at other resource objectives, with the largest allocation being in scenic travel.

Under Alternative F, timber harvest would occur on 53 percent of the lands on the Forest suitable for timber management. Less than 1% of the suitable lands would be managed under GF-1. As in Alternative E, scenic travel prescriptions occupy the most area proposed for timber management.

Alternative G would have harvest activities occurring on 64 percent of the lands on the Forest suitable for timber management. Approximately one percent of this area would be managed at the highest intensity level (GF-1), with the largest percentage, as in Alternatives E and F, being allocated to the ST-1, scenic travel prescription.

In Alternative H, timber harvest would occur on 76 percent of the suitable timber land. Approximately 11 percent will be managed at the highest intensity, with most of the remaining acres of General Forest managed under the GF-3 or moderate intensity level.

Alternative I has the same General Forest allocations as Alternative C, with harvest occurring on 73 percent of the suitable timber lands. However, Alternative I would provide a higher level of timber harvest in the first decade. Approximately 19 percent will be managed at the highest intensity, but the greatest percentage would be allocated to low intensity (GF-4) management.

Under Alternative J, timber harvest would occur on 87 percent of the tentatively suitable acres, with more area managed at the highest intensity level than in any other alternative. This would also result in the most acres of planting and thinning of all alternatives.

Vegetation: Old Growth

The variation in the effects of the alternatives on old growth relates directly to the number of activities that manipulate the old growth ecosystem. Alternatives with the least acres in intensive management prescriptions and the most acreage in non-motorized, unroaded allocations would result in the least potential for impacts to old growth. Table S-5 summarizes the relationship between alternatives in terms of acres of old growth remaining at the end of the first, second and fifth decades.

**TABLE S-5
ACRES OF OLD GROWTH REMAINING
(INCLUDING WILDERNESS)
AT THE END OF DECADES 1, 2 AND 5**

G	299,600	289,500	259,300
H	306,700	294,600	258,400
I	307,300	295,300	261,200
J	305,100	291,300	250,100

Vegetation: Forage

The forage base occurring on the Forest will be utilized to some degree by either wildlife or livestock, and in some cases both classes of animals will use the same forage at different times of the year. Forest-wide there is forage in excess of current and projected needs. However, where some key winter range areas are utilized by livestock in the summer, there may be reductions in forage below the needs of wildlife.

The numbers of permitted livestock are the same in all alternatives through the first decade. The differences will occur in the number of acres available for livestock grazing and in the amount of suitable forage that will not be used outside the existing allotments. Alternatives B, D, H, I and J have the highest number of acres available for livestock grazing, nearly double all other alternatives except E and G. This is due to the creation of transitory range as a result of the timber harvest activities in these alternatives. Existing and potential forage is high, with a moderate to high number of livestock to be used in the management of the forage. Alternatives NC, A/NFMA, C and F will use about half the available acreage as the preceding alternatives for livestock grazing, with all use confined to existing allotments. Suitable forage areas outside these allotments would not be grazed. Alternatives E and G have about 10 percent fewer acres available for livestock grazing than Alternatives B, D, H, I and J, but will serve approximately the same number of livestock. The amount of existing and potential forage that is available is high.

Vegetation: Unique Ecosystems

The number of unique ecosystems proposed for protection varies by alternative, as does the specific localities selected. In some cases, these would be protected by a Special Interest area management allocation (SI-2) and in others, by inclusion in an unroaded, non-vegetative manipulation prescription. Each area is proposed for protection in at least one of the alternatives. In addition, all alternatives include the existing Tumwater Botanical Area under the Special Interest area allocation. Table S-6 summarizes the effects on the unique ecosystems by alternative. Areas showing an "X" have a Special Interest area allocation, while areas showing an "A" are protected by an unroaded, non-vegetation manipulation prescription.

**TABLE S-6
PROPOSED SPECIAL INTEREST AREAS BY ALTERNATIVE**

AREA	ALTERNATIVES										
	N/C	A	B	C	D	E	F	G	H	I	J
Camas							X				
Gene Creek							X				
Hornet Ridge						A	X	A			
Lake Creek			X	X	X	X	X	A		X	
Kloochman Rock							X				
Goose Egg Mt			X		X		X				
Rimrock			X		X		X				
Blue Slide			X		X	A	A	A			
Upper Naneum Mdw				X		A					
Boulder Cave				X							
Squaw Lake Area				X							
Fish Lake Run				X							
Ponderosa Estates				X							

Vegetation: Sensitive Plants

Sensitive plants are protected by Forest Service policy under all alternatives. However, the higher the level of development proposed in an alternative, the greater is the risk of unintentional impacts to sensitive plants through management activities. In this sense, Alternatives J, NC, B and D would present the greatest risk of impacts, with Alternatives E, F and G presenting the least overall. Alternatives A/NFMA, C, I and H would fall about mid-range in their potential for impact to sensitive plants.

Vegetation: Research Natural Areas (RNA's)

The two existing RNA's, Meeks Table and Thompson Clover, would remain unchanged in all alternatives, as would the two formally proposed areas, Fish Lake Bog and El Dorado Creek. Four additional areas are proposed as RNA's in Alternatives B, C, D, E, F and G, but are not recommended in Alternatives NC, A or H. In these latter alternatives, vegetative manipulation (for any management purpose) or site destruction by roading may irreversibly preclude the selection of some of these areas for RNA's in the future.

Water

Both on-Forest and off-Forest users are concerned about the water quality and quantity. It is a key ingredient in maintaining fish and wildlife habitat, and scenery, as well as being of critical importance for downstream irrigation and drinking water. The intent of all alternatives is to manage watersheds to minimize the loss of soil productivity and to provide riparian area, stream channel and water quality conditions that would protect beneficial uses of water.

When the annual water yield increase by alternative is compared to the Forest's annual background runoff, the increase appears insignificant because it is "masked" by the large annual runoff figure. However, on a site specific basis such as a small watershed heavily impacted by timber harvest, stream channel erosion and degradation could occur.

The location, intensity and timing of harvest, the specific methods of treatment, and the number of roads constructed directly affect water yield and quality. The higher the timber harvest level, the greater the increase in water yield, and the more roads constructed, the greater the potential to cause a degradation in water quality. By the end of the first decade, Alternative J would have the greatest water yield increase and highest potential for damage to water resources, followed in decreasing order by Alternatives NC, B, H, I, D, C, A/NFMA, G, F and E.

Soil

Timber harvesting and road construction can result in soil productivity reduction due to compaction, displacement, puddling, erosion and loss of nutrients, and increased sedimentation that will eventually end up as delivered sediment in the streams and rivers. Each of the alternatives generates different amounts of delivered sediment. Soil compaction and nutrient loss are proportional to the amount of delivered sediment loss created by management activities. Thus, if the amount of delivered sediment increases, the amount of compacted soil and the amount of nutrient loss will also increase.

The amount of delivered sediment is directly related to the intensity of timber harvest and the level of road construction and reconstruction. Those alternatives that harvest more timber and build more roads produce more delivered sediment. Alternative J would produce the highest sediment yield, followed in decreasing order by NC, B, H, C, I, A/NFMA, D, G, F and E.

Air

The effects of smoke and haze from off-Forest sources has caused more of an impact to air quality than activities originating on the Forest. Prescribed burning and wildfires are the largest contributors to the temporary degradation of the air resource, but these are short term and the effects do not vary significantly between alternatives.

Minerals

Mineral commodities, deposit locations, and deposit characteristics will not vary by alternative, but the demand for mineral commodities is expected to increase regardless of the alternative selected. The manner in which the lands are to be managed under each alternative will have an effect on the availability of these lands for exploration. It will also have an effect on the cost of conducting exploration, development, and reclamation activities.

The consequences of the alternatives are best shown by analyzing the relative degree to which management prescriptions may limit the availability of lands for mineral exploration and development, or constrain proposed mineral activities. Thus, Alternative E has the most constraints followed by Alternatives F, G, C, I, A/NFMA, H, D, B, J and NC.

Roads

The proposed construction and reconstruction of the arterial and collector road systems reflect only minor variation between alternatives. In contrast, local roads are much more sensitive to the alternatives, varying with the amount and rate of timber harvest. All alternatives will involve new road construction, including entry into currently unroaded areas. The majority of the road construction would occur in the next 20 years. Alternative J would construct the most miles of new roads (including unroaded areas), followed in descending order by Alternatives B, D, H, I, C, A/NFMA, G, F and E.

Fire

Fire has played a significant role in the past history and management of the Wenatchee National Forest, and is expected to continue to play this role in the future regardless of the alternative chosen. Wildfire and prescribed fire are interrelated aspects of fire management. The management of fuels reduces the accumulation of residue and hence limits the number of ignitions and intensity of wildfire. Alternatives B or J would result in the most acres of fuel treatment, Alternatives E, F and G would have the least. Alternatives NC, A/NFMA, C, D, H and I would result in a mid-range of acres treated. However, the variation between alternatives in terms of fire management is not a straightforward one, since post harvest fuel treatment can also increase the potential for wildfire ignition through industrial and slash disposal activities.

Social/Economic

Changes in the levels of Forest outputs have the potential to impact employment and income levels in local communities. Timber harvest levels, which vary appreciably between alternatives, account for almost all of the variation in jobs and income.

The following table displays changes in employment and income by alternative in the first decade.

TABLE S-7
CHANGES IN FIRST DECADE EMPLOYMENT AND INCOME

ALTERNATIVES	A/NFMA	B	C	D	E	F	G	H	I	J
Change in Employment (Jobs)	+39	+577	+203	+279	-520	-473	-225	+324	+413	+630
Change in Income (Million \$)	+ 65	+15.31	+5 14	+7 20	-14 56	-13 30	-6 54	+8 43	+10 86	+16 76

Returns to the Treasury and payments to Counties also are strongly related to the amount of timber harvest. Although the increase in harvest levels has positive effects on local jobs and income, it can have negative social effects with the loss of the unroaded recreation opportunities and loss of a natural-appearing landscape. An increase in harvest levels can also have adverse impacts on the American Indian communities. These impacts would be an increased risk to cultural sites and anadromous fish, and the alteration of the environmental setting around traditional Indian use areas.

SUMMARY OF MITIGATION MEASURES

A wide-range of mitigation measures are available to avoid, reduce, remedy or eliminate adverse environmental effects that occur as a result of management activities. The Forest-wide standards and guidelines would specifically assure mitigation of potential adverse impacts. For example, the Appendix J Best Management Practices are an example of mitigation measures developed to protect water quality.

Other examples of mitigation measures available in all alternatives include: the use of Forest Service manuals and handbook guides; the use of visual management practices in harvest activities to maintain a natural-appearing setting; the use of aerial or full suspension logging systems to protect cultural resources; the establishment and monitoring of limits of acceptable change for reducing impacts in Wilderness areas; the replanting of harvest units with mixed tree species to minimize tendencies towards monoculture; the use of fertilizer to mitigate management practices which reduce productivity; the adjustment of utilization standards for grazing to provide for plant needs, and soil and water protection; more complete use of wood residue to mitigate effects of prescribed fire; and the use of road closures for reducing impacts on wildlife and some types of recreation.

The effectiveness of these measures would vary according to the nature, intensity and location of the activities that are producing the impact, and hence would not work equally well in all alternatives. A detailed discussion of mitigation measures by environmental component appears in Chapter IV of the FEIS.

SHORT-TERM USES VS. LONG-TERM PRODUCTIVITY

The relationship between the short-term uses of man's environment and the maintenance and/or enhancement of long-term productivity is complex. For the purposes of this assessment, short-term uses are those that generally occur on a yearly basis on some area of the Wenatchee National Forest, such as timber harvest as a use of the wood resource, livestock grazing as a use of the forage resource, and recreation and irrigation uses of the water resource.

"Long-term" refers to longer than a 10 year period. Productivity refers to the capability of the land to provide market and amenity outputs and values for future generations. For example, maintenance of long-term soil productivity requires that activities which cause excessive erosion, compaction, and other adverse impacts to soil be mitigated. Occasionally short-term uses will cause substantial damage to isolated areas. Direction in Chapter IV of the Forest Plan contains management requirements designed to protect soil and water resources so that long-term productivity is not significantly impaired.

ENVIRONMENTAL CONDITIONS UNCHANGED BY THE ALTERNATIVES

Some resources on the Forest are not affected by any of the alternatives. The land area designated as wilderness is the same in each alternative. Within wilderness, the physical and biological environmental conditions would remain unchanged between alternatives.

In all alternatives, the land allocations designed by the Alpine Lakes Area Land Management Plan do not change.

Thompson Clover and Meeks Table Research Natural Areas, and the Entiat Experimental Forest have all been designated by the Chief of the Forest Service and will remain unchanged across all alternatives.

Existing and proposed utility corridors do not vary by alternative. It is estimated that a maximum of four small hydroelectric projects would proceed to the stage of applying for a license to build and operate a project. Thus, there is little difference in these effects between alternatives.

PROBABLE ADVERSE ENVIRONMENTAL EFFECTS THAT CANNOT BE AVOIDED

Implementation of any of the alternatives will inevitably result in some adverse environmental effects that cannot be avoided. The degree of severity of the adverse effects can be minimized by adhering to the direction in the management prescriptions and Forest-wide Standards and Guidelines in Chapter IV of the Forest Plan, but some impacts generally cannot be avoided if any management activities occur.

Soil disturbance occurs as a result of timber harvest slash treatment, wildfires, and construction of utility corridors, roads, trails, and recreation sites. Both the technique and the scheduling of management activities can affect the kind and amount of impact that can occur on soil resources. This is also true for water resources. Short-term effects on water are a result of management activities such as timber harvest, wildfire, livestock use, and recreation use.

Effects on visual quality are generally of a short-term nature from activities such as timber harvest. Long-term effects on scenery would be from wildfire, roads, and utility corridors.

Air quality may be temporarily degraded in localized areas by both prescribed fire and wildfire. Wildlife can be adversely affected by fire, small hydro development, and timber harvest activities. And finally, it is likely that some significant cultural resource sites will inadvertently or unavoidably be disturbed.

IRREVERSIBLE OR IRRETRIEVABLE COMMITMENT OF RESOURCES

Acres committed to roads and facilities constitute an irretrievable loss of vegetative production and an irreversible loss of soil productivity. When roadless areas are developed they represent an irreversible effect on the roadless values associated with them.

Timber resources can be irretrievably lost by being dedicated as old growth or by being located within designated wilderness. Insects, disease and fire can also cause irretrievable losses. Use of mineral and energy resources can have both irreversible and irretrievable effects.

CHAPTER I

PURPOSE AND NEED

A. INTRODUCTION

This Final Environmental Impact Statement (FEIS) discloses eleven alternatives, including an alternative identified as the Preferred Alternative (which is the "proposed action"). These eleven alternatives are alternate ways of managing the land and resources of the Wenatchee National Forest (See Chapter II). This FEIS also describes the environment which would be affected (Chapter III), and the environmental consequences of implementing each of the alternatives (Chapter IV).

Each alternative represents a different way to address local, regional, and national public issues and management concerns, provide for use and protection of resources, and fulfill legislative requirements. Every alternative generates a different mix of goods and services from the Forest.

For this plan, multiple use and sustained yield become the guiding principles. Each alternative was evaluated to determine its potential to provide a sustained yield of goods and services in a way that maximizes long-term net public benefits in an environmentally sound manner.

The Preferred Alternative is the alternative which the Forest Service believes would maximize long-term net public benefits while responding effectively to the resources issues and concerns. Net public benefits represents the cumulative net value of all Forest outputs and activities, whether assigned a dollar value or not. The key indicator for this principle is the comparison by alternative of Present Net Value changes or tradeoffs with quantitative indicators of response to the issues, concerns, and opportunities.

The Preferred Alternative, as modified by the Record of Decision, is the basis for the accompanying "Wenatchee National Forest Land and Resource Management Plan" which is a separate document. The purpose of the Forest Plan is to direct all natural resource management activities on the Forest. While the Forest Plan will guide the management of the Forest for the next 10 to 15 years, the analysis for the FEIS covers a planning horizon of 50 years to evaluate and display the long-term effects of current actions.

Preparation of the Forest Plan is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), plus the associated National Forest System Land and Resource Planning Regulations (36 CFR 219 - Refers to Part 219 of Title 36 of the Code of Federal Regulations dated 9/30/82).

The preparation of an Environmental Impact Statement disclosing a preferred alternative and a broad range of additional alternatives is required by the National Environmental Policy Act of 1969 (NEPA), the Council on Environmental Quality (CEQ), NEPA Regulations (40 CFR 1500), and the implementing regulations of NFMA (36 CFR 219). For purpose of disclosure under NEPA, this FEIS and the accompanying Forest Plan are treated as combined documents.

The Environmental Impact Statement is required because the Forest Plan is a major Federal action with a significant effect on the quality of the human environment. Its purpose is to provide decision-makers with an environmental disclosure sufficiently detailed to aid in the selection of management direction for the Forest. Equally important, its purpose is to make information of the alternatives' environmental impacts available to the public, and to encourage public participation in the development and refinement of that information.

A Glossary defining terms, units, and abbreviations is located just in front of the Index. A list of references and a list of preparers are also provided. The reader will find it useful to consult the land management allocation maps for each alternative when reviewing this FEIS. Since each alternative depicts different combinations of management areas, the reader should also become familiar with the direction and emphasis for each management area (See Chapter II).

B. CHANGES BETWEEN DRAFT AND FINAL

The Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan were released to the public in June 1986. A Supplement to the DEIS was released in October 1988. Changes that have occurred since the DEIS are incorporated in this Final EIS. These changes include numerous updates of information as well as responses to public involvement in the planning process. The discussion under Planning Problems gives more information on issues which were ratified and some which were given fresh emphasis such as roadless areas, timber harvest levels, Wild and Scenic River recommendations, and the old growth/spotted owl issue.

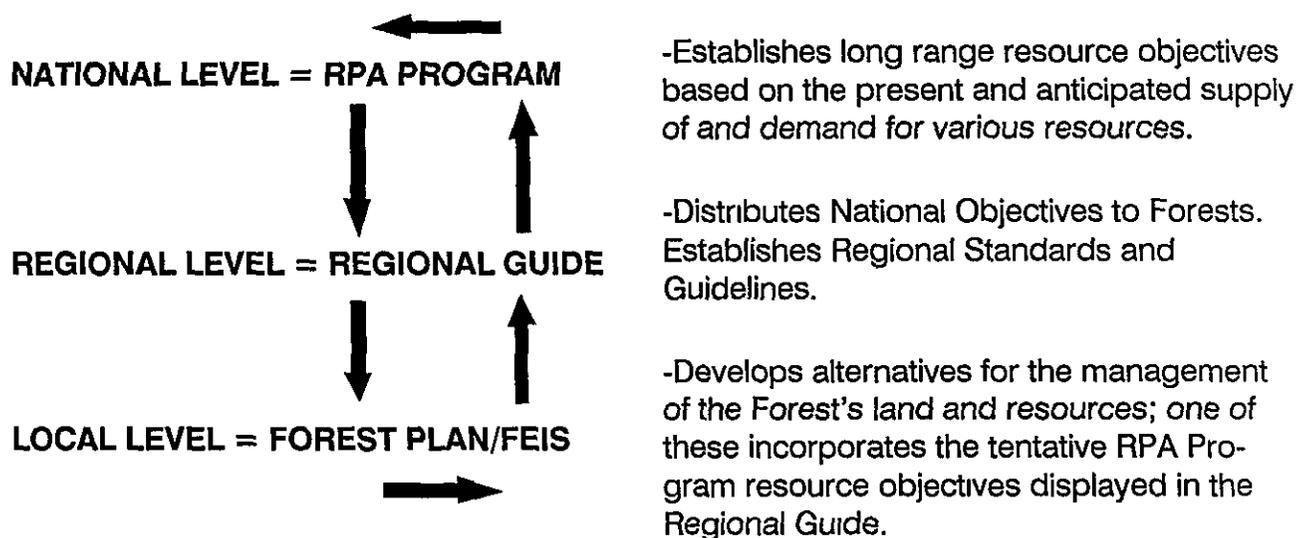

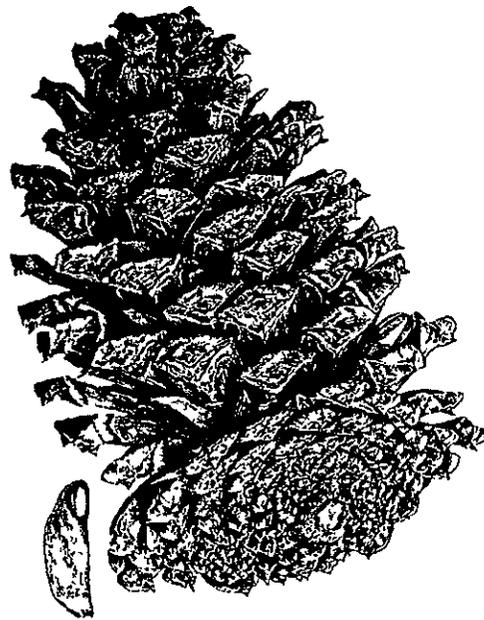

In response to public input, a comprehensive review was made of motorized trail use on the Forest. The review resulted in a change in trail management philosophy which allows for no net increase in mileage of motorized trails. Another major review was also made of future management of the current roadless areas. As a result, numerous boundary changes were made as well as two new prescriptions in the preferred alternative, for roadless timber harvest and for roadless wildlife emphasis. The EW-2 riparian area management prescription was extensively revised in response to comments asking for better protection of the water/fish resource. Wildlife direction for species dependent on the mature/old growth habitat was changed substantially with one prescription developed for dedicated (no timber harvest) and one for managed old growth. Timber harvest levels for all alternatives changed primarily from new direction for Management Requirements with other effects resulting from changes in the FORPLAN computer model.

The Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (USDA, 1988) that addresses spotted owl guidelines has been completed since the Wenatchee DEIS. The changes in direction from the new guidelines have been incorporated in this FEIS resulting in changes to alternative outputs, the spotted owl habitat area network, and the Forest Plan Standards and Guidelines. The EIS for

Managing Competing and Unwanted Vegetation (USDA, 1988) was also released since the DEIS. The analysis in the FEIS and Forest Plan for the Wenatchee National Forest assumes that all methods of managing competing vegetation are available.

C. PLANNING PROCESS

To put Forest Planning in perspective, it is important to have a general understanding of the overall Forest Service planning process. As required by the RPA, NFMA, and related implementing regulations cited above, the Forest Service has a three-level integrated planning process:

Information on resources available and public demand for the resources of each National Forest is incorporated in the RPA Assessment and Program. The RPA Program is submitted to Congress as an aid to determine appropriation of the annual Forest Service budget. Since allocations in the annual budget have a major effect on forest management activities, many of the Forest's actual outputs and resulting environmental effects are ultimately determined in large part by the annual budget. Through the overall planning process the annual budget can be responsive to public needs and Forest capabilities.

The planning process is a continuously repeating process in that the information from the Forest level flows up to the National level, is incorporated in the RPA Program, and then flows back to the Forest level.

The RPA Program and Regional Guide are updated every five years. The Forest Plan is reviewed every 5 years and is ordinarily revised on a 10 year cycle or when changes in the RPA Program significantly affect Forest Programs. It must be revised at least every 15 years. It will also be revised whenever conditions or demands in the area covered by the Forest Plan change significantly. This process ensures that the Forest Plan is responsive to changing conditions.

The planning process specified in the NFMA implementing regulations, the environmental analysis process specified in the NFMA implementing regulations, and the environmental analysis process specified in the CEQ regulations were used in developing this FEIS and the accompanying Forest Plan. The planning steps employed are:

1. Identification of purpose and need (including public issues and management concerns)
2. Development of planning criteria
3. Inventory of data and information collection
4. Analysis of the management situation
5. Formulation of alternatives
6. Determination of estimated effects of the alternatives
7. Evaluation of alternatives
8. Selection of the Preferred Alternative and documentation of its proposed implementation in the Forest Plan
9. Plan approval
10. Plan Implementation
11. Monitoring and Evaluation

The results of the environmental analysis are documented in this FEIS. It ensures that environmental information is available to public officials and citizens before decisions are made and before actions are taken.

Upon implementation, the FEIS will be used for "tiering" in accordance with the CEQ regulations. Tiering means that environmental analysis prepared for projects arising from the Forest Plan will refer to the FEIS for coverage of the broader issues rather than repeat information. Environmental documents for specific projects will concentrate on issues unique to those projects (50 CFR 1508.28).

The Forest Plan supercedes all previous land management plans prepared for the Wenatchee National Forest except the Alpine Lakes Area Land Management Plan. All resource plans will be consistent with the Forest Plan. The Forest Plan incorporates the management direction in the Alpine Lakes Area Land Management Plan and Environmental Impact Statement (1981) that was Congressionally mandated through the Alpine Lakes Management Act (36 CFR Part 219.2(b)).

Upon implementation, all subsequent administrative activities affecting the Forest, including budget proposals, will be consistent with the Forest Plan. Actual budgets appropriated by Congress may alter the schedule of proposed activities. In addition, all permits, contracts, and other instruments for the use and occupancy of National Forest System lands must be revised to conform with the Forest Plan subject to valid existing rights (36 CFR 219.10(e)). Within the Alpine Lakes Area the Alpine Lakes Area Land Management Plan is the guiding document when there is a conflict in management direction between it and the Forest Plan.

Table I-1 shows how existing land and resource plans would be affected by the final Forest Plan

D. OVERVIEW OF THE FOREST'S LOCATION

The Wenatchee National Forest lies on the east side of the Cascade Mountain Range in Central Washington (Figure I-1). It extends about 140 miles from north to south and an average of 35 miles east to west. The Forest has a net area of 2,164,180 acres (larger than Delaware and Rhode Island combined).

Steep, rugged mountains and heavy snowpacks characterize the western portions of the Forest. In contrast, near desert conditions prevail in the eastern grass and shrub covered foothills and valleys. Between the two extremes are diverse forest and plant communities resulting from the variations in soils, elevation, aspect, temperature, precipitation, and fire influences. The major drainage systems include the Chelan, Entiat, Wenatchee, Upper Yakima and Naches-Tieton River systems. All flow eastward toward the Columbia River. Principal forest resources include timber, forage (for wildlife and livestock), recreation, water, and wilderness. Almost two out of every five acres on the Forest (39 percent) are Congressionally designated wilderness.

The Forest is primarily located in Chelan, Kittitas, and Yakima Counties, with two acres in Douglas County. The area administered by the Wenatchee National Forest and considered in this planning includes a 515,843 acre parcel of the Mt Baker-Snoqualmie National Forest. These lands are the Naches Ranger District in the southern portion of the Forest. In addition, an isolated 9,032 acre parcel of the Wenatchee National Forest in the Liberty Bell portion of Chelan County is being administered by the Okanogan National Forest and will be included in the Okanogan Forest Plan.

Major cities and towns in or near the planning area are Chelan, Entiat, Cashmere, Leavenworth, Wenatchee, and East Wenatchee in the north, Cle Elum, Roslyn, and Ellensburg in the center, and Yakima, Selah and Naches in the south. More than 270,000 people live in the four county area. The Forest is also easily accessible from the metropolitan Puget Sound Area (Figure I-1).

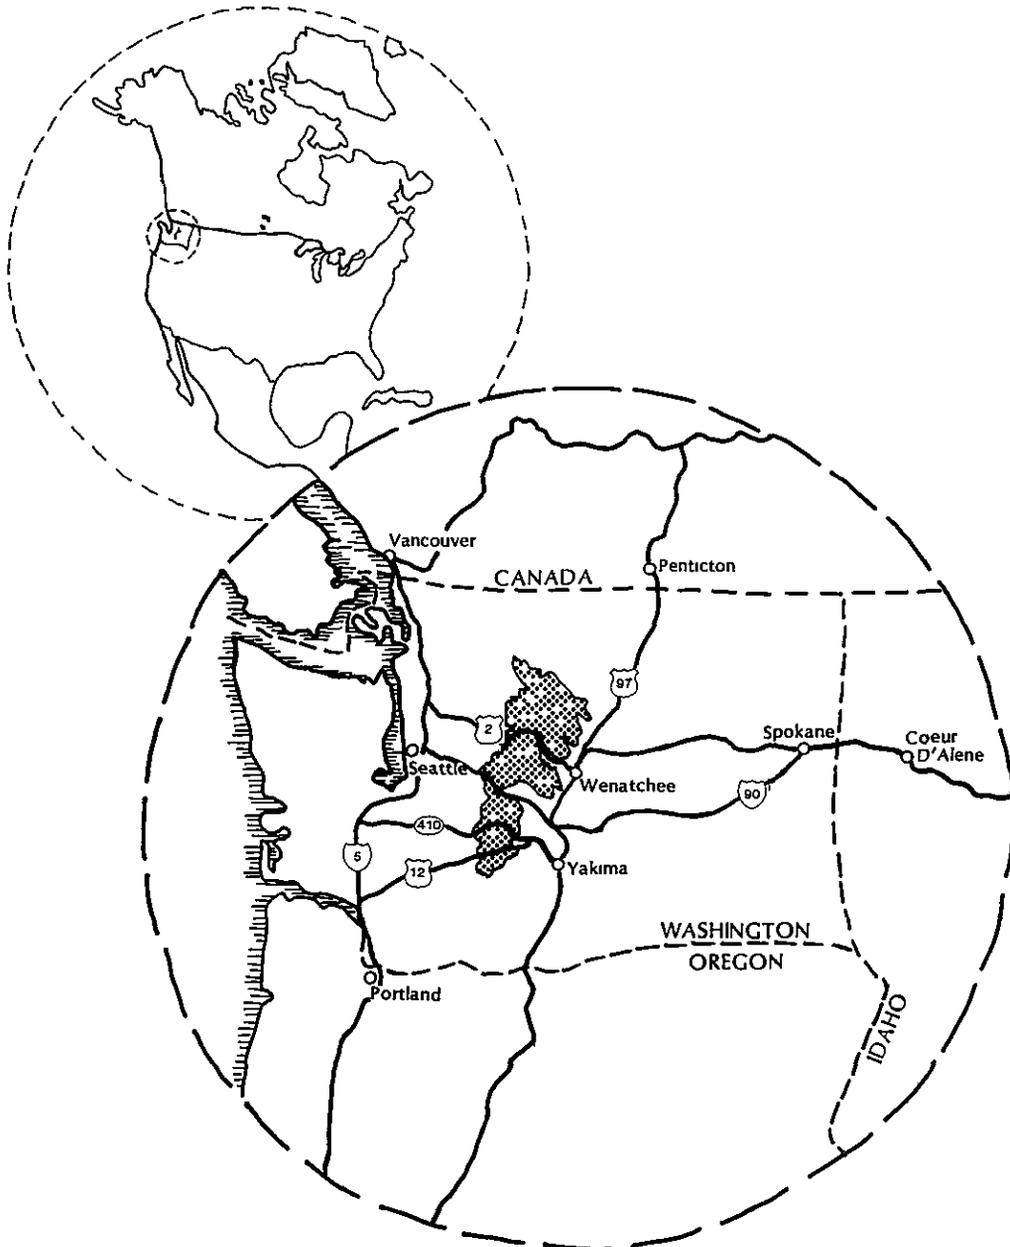

The Forest occupies a portion of the lands ceded to the U.S. Government by the Yakima Indians in 1855. The Yakimas retained certain rights on these lands through the Treaty of 1855.

The Forest headquarters is in Wenatchee, Washington. There are six Ranger Districts:

- Chelan Ranger District**
- Entiat Ranger District**
- Leavenworth Ranger District**
- Lake Wenatchee Ranger District**
- Cle Elum Ranger District**
- Naches Ranger District**

Further details on the Forest's environment and setting are in Chapter III of this FEIS.

VICINITY MAP
WENATCHEE NATIONAL FOREST**

E. ISSUES, CONCERNS, AND OPPORTUNITIES

The Wenatchee National Forest consists of complex natural systems that can be managed for different mixes of resource outputs, land uses, and environmental conditions. Different people and groups prefer to see the Forest managed to emphasize different outputs, uses, and conditions. Because all the resources, uses, and conditions of a forest are interconnected, managing to emphasize some resources results in changes in others. Trade-offs are necessary when management emphasis adversely affects resources or other uses. There are practical and natural limits to a Forest's productivity.

A central Forest Planning task is analyzing the alternative ways of managing the National Forest. The analysis must also determine the effects of these alternatives on the environment and on existing and human uses. The public desires for goods, services, uses, and environmental protection help to determine the alternative management practices that will be formulated and analyzed.

These different preferences of individuals and groups, and the physical, biological, and legal limits of Forest management are represented in the issues and concerns which guide the planning process. A public issue is a subject or question of widespread public interest relating to management of the National Forest System.

A management concern is an issue, problem, or a condition which limits the range of potential management practices identified by the Forest Service in the planning process.

A third component influencing alternatives comes from the various opportunities for resource use and development suggested by both the public and the Forest Service. The opportunity to preserve or develop and use the resources of the National Forest is the focus of many of the agency's programs, and the principal focus of the management alternatives developed here. Because there are both public issues and management concerns related to these opportunities, most of them are incorporated within the discussion of issues and concerns. Resource use and

development opportunities, along with the issues and concerns, are identified and discussed in Appendix A.

An important step in the planning process is the identification of major public issues and management concerns. This was accomplished through an extensive process involving individual members of the public, adjacent private landowners, other Federal agencies, State and local governments and agencies, local industry, conservation groups, user groups, and Native Americans. In early 1979, all existing Wenatchee National Forest land and resource management plans were reviewed and a list of 85 tentative issues was developed for public review and comment. That list had been put together by employees of the Wenatchee National Forest based on their dealings with the public and their knowledge of Forest concerns.

To help identify any remaining issues which should be addressed in the Wenatchee Forest Plan, planners went to the public for help in 1979. The original list of 85 issues was mailed to about 1,900 people in the search for additional issues. There were public workshop sessions in Wenatchee, Yakima, Tacoma, and Seattle, and there were meetings between the planners and more than 25 other federal agencies, State and local governments, Indian tribes, and owners of private land within and adjacent to the Forest.

Comments from 230 response forms and letters plus the results of the public workshop sessions and meetings were reviewed and analyzed to arrive at a final set of issues to be addressed in the Wenatchee Forest Plan. Since this list was developed, several issues were resolved, and several other issues increased in importance and were added to the list of issues.

With the passage of the Washington State Wilderness Act of 1984, former Issue #13, "Allocation of Areas Designated for Further Planning by RARE II," is no longer applicable. Much of the Goat Rocks Further Planning Area was added to the Goat Rocks Wilderness. The future management of the balance of this unroaded area and others on the Forest will be decided in the Forest Plan. In addition, four new issues and concerns were added to the original list: #13, Minerals; #14, Cultural Resource Management; #15,

Cumulative Effects, and #16, Social-Economic. In December of 1984 the public had another opportunity to respond to the revised list of issues, concerns, and opportunities through a Forest Plan Report #10 mailing and public meeting. There were 2,300 Forest Plan Reports mailed and 100 responses were received.

The issues list is dynamic and can be added to or changed as new or different issues surface. Due to the public input to the DEIS and Supplement, two new issues were added. These are #17, Wild and Scenic Rivers; and #18, Old Growth. Further information on the development of the ICO's is available in Appendix A in the FEIS or the Planning records of the Wenatchee National Forest.

Public involvement occurred throughout the planning process. Forest Plan Reports were sent to the public, agencies, State and local governments, Indian tribes and major private landowners at key points in the planning process. Public comment was encouraged. Information meetings were also held with interest groups, Indian tribes, and Federal and State agencies. The public, agencies, and Indian tribes had another opportunity to respond to the planning effort by commenting on the DEIS and accompanying Proposed Forest Plan.

The listed issues (Appendix A) were used to help formulate the various alternatives discussed in the following chapter. Table II-1 in Chapter II shows how the issues are linked with the alternatives and how they are resolved.

The ICO's for planning were ratified again through extensive public involvement received after publication of the DEIS, Proposed Forest Plan, and the Supplement to the DEIS. The Forest received a total of over 4,700 responses to the DEIS, and the Supplement received 2,650 responses. Numerous meetings with interested agency officials, groups, and individuals have continued to clarify ICO's. As a result of the public review process, two new issues (Wild and Scenic Rivers, and Old Growth) were added to the original list. Appendix K describes the public involvement process from the DEIS, through the Supplement, to the FEIS. It also displays public comments received and the Forest response to the comments.

An analysis of the issues (Appendix A) determined that 10 of the 18 issues were most important in formulating the various alternatives for the Wenatchee National Forest Plan. However, all 18 of the major issues influence the alternatives to some degree. In Chapter II, the alternatives are compared to determine how well they respond to all the issues and how these ICO responses relate to changes in Present Net Value. The ten most important issues are stated below as planning problems:

PLANNING PROBLEM #1

Are Forest lands capable and suitable of meeting public demand for particular types of recreation use? Where are these lands located?

Opinions are divided on the quantity and type of recreational facilities and opportunities the Forest should be providing. Some people want increased opportunities for unroaded non-motorized recreation outside of designated wilderness while others want increased opportunities for motorized recreation and developed sites. Opinions also differ regarding the use and restrictions of off-road vehicles (ORV's).

Some people are strongly opposed to ORV use in any way because of perceived impacts on soils, vegetation, and wildlife. There is also an expectation of incompatibility with their recreation experience from noise pollution in narrow canyons. Other people believe impacts are really insignificant or overstated and feel that relatively unlimited use of ORV's is acceptable.

There is a demand to expand existing developed recreation sites such as Mission Ridge and White Pass Ski Areas and developed campgrounds, or to construct new developed sites. On the other hand, there are those who prefer minimum development sites and the expansion of cross-country skiing opportunities.

Conflicts between recreation and other Forest values are frequently mentioned. For example, the visual effects of clearcutting are generally considered to be incompatible with recreational

values. The need and potential for special classification areas such as Research Natural Areas, Scenic areas, and Botanical areas are also mentioned.

PLANNING PROBLEM #2

What kinds of recreational opportunities should the Forest provide in non-wilderness roadless areas, and how much of the roadless areas should be allocated to commodity production?

The public is strongly divided on the future management of the remaining 556,272 acres of roadless areas. Some people would like to develop the timber and other commodity potentials of these areas. Others would like these areas to remain roadless and undeveloped. Some prefer a balance between commodity use and roadless recreation based on land suitability and multiple use. Wilderness proponents support the management of some roadless areas to maintain their potential for future additions to the Wilderness Preservation System.

PLANNING PROBLEM #3

What rivers and streams should be recommended to Congress for inclusion into the Wild and Scenic Rivers system, and at what level of classification?

This planning problem was considered a part of planning problem #1 (suitability of lands for recreation use) in the DEIS, but due to public response to the Draft, the Wild and Scenic Rivers section was greatly expanded in the 1988 Supplement to the DEIS.

Some people believe that all of the rivers and many streams on the Forest should be included in a preliminary administrative recommendation to Congress for consideration under the Wild and Scenic Rivers Act. Other people are strongly opposed to the recommendation of some or all rivers and streams (or certain segments), particularly rivers or segments of rivers with private lands within the river corridor. Some are also concerned with the level of classification proposed for those river segments outside wilderness.

PLANNING PROBLEM #4

How should water quality and quantity be maintained or enhanced?

The public is sensitive to the need to protect soil and water resources. Many people realize that improperly conducted management activities can cause damage to these resources.

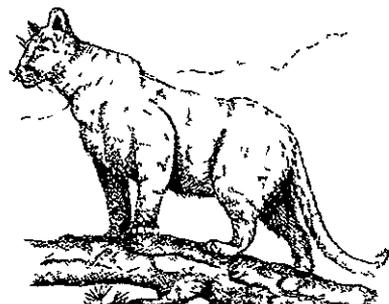

People living downstream of the Forest are concerned with the quantity of water for irrigation, as is the case in the Wenatchee and Yakima valleys. Other people, including the Yakima Indians, are concerned about fish habitat and instream needs for fish migration.

PLANNING PROBLEM #5

Where are the essential wildlife habitats, how should they be managed and what direction should be taken to maintain or enhance wildlife diversity?

Some people believe that wildlife and fish management has not received appropriate attention within the Forest. Others believe there should be more emphasis on wildlife needs through coordinated timber or range management activities. The future management of anadromous fish habitat and old-growth forest dependent species such as the northern spotted owl, pileated woodpecker, and marten is a major concern of another segment of the public. Other people are concerned that management for these wildlife species will seriously deplete the amount of timber available for harvest.

Wildlife management requires close coordination with the Washington Department of Wildlife. Many comments expressed the need to better coordinate other Forest management activities with wildlife concerns.

PLANNING PROBLEM #6

How should Old Growth be treated? How much should be preserved and how much should be made available for timber harvest?

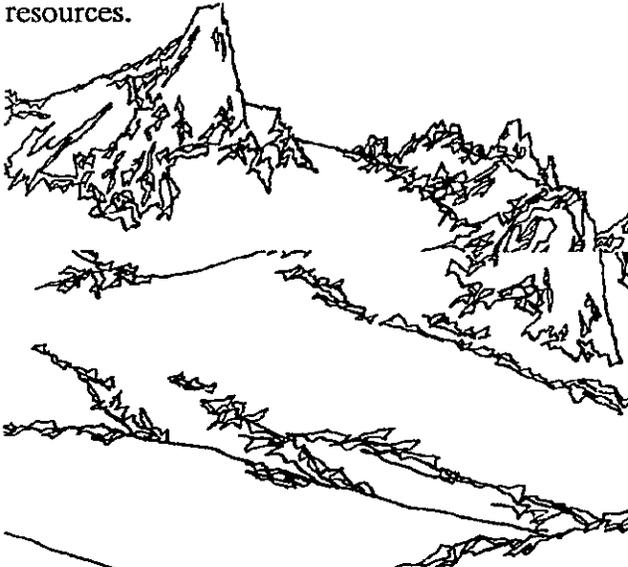

This planning problem was originally considered a part of planning problem #5 (essential wildlife habitats) in the DEIS, but due to public response to the Draft and Supplement, it was decided to make this a separate planning problem.

Some people believe that all existing old growth on the Forest should be preserved for biological diversity, dependent wildlife species, scenery or esthetic values, and/or because they feel that no more old-growth forest will remain in a few years. Others believe that both existing and potential old growth within designated wilderness is more than enough to meet all future needs.

PLANNING PROBLEM #7

Where are the key or unique scenic resources on the Forest and how should they be managed?

Most recreation visitors to the Forest are concerned about maintaining or enhancing the scenic quality of the environment. Others would like to see the Forest managed for wood fiber with few, if any, visual considerations. Some favor the maintenance of scenic quality only in key travel corridors. Others stress the multiple use benefits of maintaining scenery in combination with other resources.

PLANNING PROBLEM #8

How much timber should be produced, and where should it be produced?

Most people support timber management and harvesting on the Wenatchee National Forest. However, there is concern about harvest location, logging practices used, and their effects on other resources. Some people want increased emphasis on protection or preservation of scenery with little or no development. Others want increased wildlife habitat emphasis while allowing moderate development opportunities. Others favor intensive management of commercial timber species, with full development of consumptive uses.

PLANNING PROBLEM #9

What level of livestock grazing should the Forest provide?

Opinions differ on the use of public land for livestock grazing. Some feel that cattle and sheep cause damage to Forest resources and that commercial grazing is not a cost-effective use of the Forest's resources. Others strongly favor grazing as a viable use of available forage and would expand this use as a tool to enhance other resource values. Timber harvest practices to increase available forage are favored by some.

PLANNING PROBLEM #10

Where are the cultural resource sites on the Forest, and how should they be managed?

The American Indian community has strong concerns about the preservation of Indian cultural resource sites and traditional use areas. There are also local community concerns about the protection and interpretation of cultural resource sites. A central concern is to provide a balance between other resource uses and the protection of individual cultural resource sites.

F. SUMMARY OF PUBLIC PARTICIPATION

The ICO's which had been developed for the Draft EIS were ratified again through extensive public comment received after publication of the DEIS, Proposed Forest Plan, and the Supplement to the DEIS. For the DEIS and proposed Plan, the Forest had a 120 day review period during which it received over 4,700 responses. The Supplement to the DEIS had a 90 day review period and received about 2,650 responses.

Several issues or aspects of ICO's received fresh emphasis after the issuance of the Draft in 1986 and the Supplement in 1988. As mentioned previously, two new issues were added because of public input. Numerous meetings with interested agency officials, groups, and individuals since then have continued to clarify the ICO's. Appendix K describes the public involvement between the DEIS and FEIS. It also displays the public comments received and responses to the comments.

G. PLANNING RECORDS

All of the documents and files that chronicle the Wenatchee National Forest planning process, including the environmental analysis, are available for review at the Supervisor's Office, 301 Yakima Street, P.O. Box 811, Wenatchee, Washington 98807. These documents and files, known as planning records, contain the detailed information and decisions used in developing the FEIS and the Forest Plan. The planning records are referenced at appropriate points in the text and appendices of this FEIS and Forest Plan.

CHAPTER II

ALTERNATIVES, INCLUDING THE PROPOSED ACTION

A. INTRODUCTION

This chapter is the heart of the Environmental Impact Statement. In this chapter, alternate ways of managing the National Forest (the Alternatives) are presented and their resource outputs and environmental effects displayed. There are also discussions of how these Alternatives were developed and how they compare to each other and to current Forest management. This chapter draws on material from later chapters. Chapter III describes the affected environment. Chapter IV presents the environmental consequences.

1. Overview of Chapter II

There are three main parts to this chapter. First there is a summary of the analysis that was conducted in the process of developing the alternatives. (A much more detailed presentation of this analysis is presented in Appendix B, Description of the Analysis Process.) Next, the purpose and management emphasis of each alternative is described. Finally, the alternatives are compared directly to each other. This comparison shows the response to issues, the emphasized land uses, the resource outputs, the environmental effects, and the economic costs and benefits which will occur with each alternative.

2. Changes Made Between Draft and Final

A new Alternative, Alternative J, was added in response to public comment. This Alternative was developed by timber industry representatives who referred to it in the public input as the "Essential Alternative."

In all Alternatives the Mature/Old Growth Management Requirement network was revised. The number and size of Spotted Owl Habitat Areas (SOHA's) was increased in response to the Supplement to the Regional Guide EIS. Management of the SOHA's changed from a "managed" to a "dedicated" prescription which does not allow scheduled timber harvest.

Due to public comments, Alternatives A/NFMA, C, E, F, G, H, and I all have different proposals for Wild and Scenic Rivers classification than shown in the DEIS. Alternatives C, E, F and I have the new prescription MP-1 for the Mather Memorial Parkway on the Naches Ranger District.

Road and trail management direction have changed from the Draft. More roads will be closed and off-road vehicle trail mileage will not increase.

Alternative C, the preferred, has numerous changes in allocation boundaries as well as the addition of two additional prescriptions: RE-4 Dispersed Recreation, Unroaded, Timber Harvest; and EW-3 Key Big Game Habitat, Unroaded.

Best Management Practices (BMP's) were added as mitigation common to all alternatives in response to public comment (also see Appendix J).

A number of changes were also made in the modeling used for analysis of the alternative (also see Description of the Analysis Process).

a. Growth was updated on existing timber yield tables to reflect new growth since the original yield tables were constructed. Acres that were cut-over since the original model was built were changed to reflect this in the FORPLAN runs for the final.

b. The original FORPLAN model had a commercial thinning constraint that limited commercial thinning volume to 29 percent of the total volume for the first decade. After the first decade, commercial thinning volume could not vary by more than +50 percent from the previous decade. It was discovered that this constraint also applied to shelterwood entries. After examination of this constraint, it was discovered that there was no need to limit shelterwood entries, and that commercial thinning entries were a very small portion of first decade harvest. This constraint was, therefore, dropped from the model for the FEIS.

c. The 1978 version of IMPLAN was used to predict changes in jobs and income in the DEIS. For the FEIS, the updated 1982 version of IMPLAN was used.

d. Deer and elk winter range (EW-1) was originally managed under Special Prescription Yield Tables 2 and 3. These yield tables included managing the timber on a fairly long rotation. Since cover and early forage production were considered more important, Yield Table RM-1 was considered to be more appropriate for winter range in the FEIS.

e. In the DEIS, the spotted owl, pine marten, three-toed woodpecker, and pileated woodpecker were managed using the same prescription and modeled with the same yield table. The DEIS also had only one spotted owl network while the FEIS uses three different networks that meet or exceed direction contained in the Final Supplement to the EIS for an amendment to the Regional Guide for Spotted Owl Guidelines. For example, the minimum owl network is used in the maximum commodity alternatives. Another difference in the FEIS is that a separate prescription was written for the spotted owl. The Spotted Owl Yield Table changed from managed old growth to dedicated old growth (no scheduled timber harvest). The prescription for the pine marten and three-toed and pileated woodpeckers was also changed to

one that produces the mature timber requirements for these species. As a result, the analysis of management requirements has also changed (see Appendix I and Management Requirements Section in this chapter).

f. Management direction for primary cavity excavators was changed resulting in a two percent reduction in the harvest volume.

g. Changes in the alternative formulations and modeling parameters resulted in the benchmark data displayed in the DEIS being no longer comparable to the alternatives displayed in the FEIS. This update was completed outside the FORPLAN model. See Appendix B for further information.

3. Alternatives

The eleven alternatives considered in this Final Environmental Impact Statement display different ways of managing the lands and resources of the Wenatchee National Forest. They may differ from each other in the land uses and management practices which would occur on different parts of the Forest. They may also differ in their scheduling of management activities.

Each alternative is a unique combination of land allocations, management prescriptions, and activity schedules. As a result, each alternative would generate a different mix of goods and services for the public, and a different combination of resource outputs, land uses, and environmental effects.

a. Constants Throughout All Alternatives

Management of some areas on the Forest will not vary by alternative. These include all Congressionally designated Wilderness areas and the Alpine Lakes Management Unit. The direction for the Alpine Lakes Management Unit is included in the recently completed (1981) Alpine Lakes Area Land Management Plan that was Congressionally mandated through the Alpine Lakes Area Management Act of 1976. This is in accord with 36 CFR Part 219.2(b) of the National

Forest Management Act of 1976 (NFMA) planning regulations. Two established Research Natural Areas, and the Entiat Experimental Forest are also constant across the alternatives. Alternative NC differs from the others as it make no allowance for the Alpine Lakes Management Unit or Entiat Experimental Forest, and does not include management requirements (MR's) per 36 CFR 219.27.

The management of some resources on the Forest will not vary by alternative. Watersheds will be managed at levels which minimize the loss of on-site soil productivity as well as provide riparian, fishery stream channel, and water quality conditions which would protect beneficial uses of water. Management of the air resource by compliance with federal, state, and local statutes will be the same in all alternatives. Appropriate wildfire responses will be implemented under all alternatives.

The final determination of timber harvest method will be made on a site-specific level for each project. All alternatives would employ combinations of the silvicultural systems applicable on this Forest. Options of designing alternatives using a single system (either even-aged or uneven-aged) were not built into the alternatives due to the tremendous physical and biological variation found within the Forest and the multiple objectives associated with each alternative. Clearcut, shelterwood, seed tree, single-tree selection, and group selection harvest methods are all available tools under each alternative. The Standards and Guidelines (Chapter IV of the Plan) indicate the system generally appropriate for given combinations of site and stand conditions, and management goals and objectives. Appendix H of the FEIS presents a discussion of the various systems, comparisons of their effects, and rationale for uses under different conditions. The systems indicated as most appropriate for the broad categories presented should be those most often used; however, it is not intended that other systems should not be used when site-specific conditions warrant. The final selection of a silvicultural system for a specific site is left for the silvicultural prescription. This is consistent with Criterion 6 of Section I-1 of the Standards and Guidelines in the Regional Guide for the Pacific Northwest Region (USDA Forest Service, 1984).

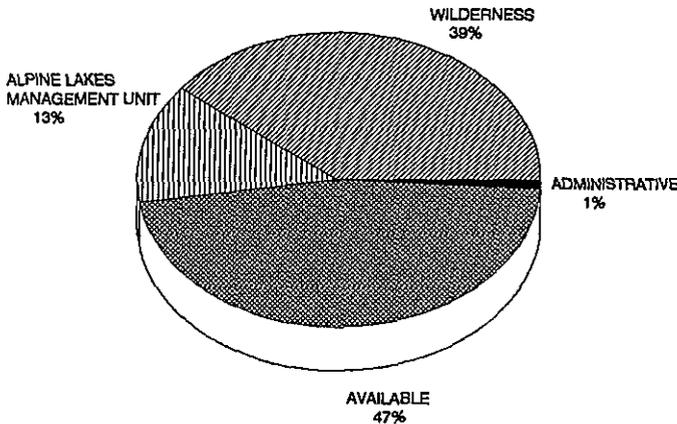

Logging systems will also be matched to the site specific conditions, and systems will be selected to meet the resource objectives at the least cost. Specific areas suitable for only some systems have not been identified by alternative. All systems will be available, including helicopter, and will be used where appropriate. The cost data used in the analysis includes allowances for this mix of logging systems in the timber program.

The Forest Service is not proposing the construction of the Naches Pass Road and there is no current proposal to construct a road by any of the intermingled landowners. Any future proposal would be subject to a site specific Environmental Analysis and the public would have the opportunity to participate in that process.

Currently 39 percent of the Forest is wilderness, 13 percent is within the Alpine Lakes Management Unit, and 2 percent is within other fixed land allocations. Thus, the land allocation on more than half of the Forest is already set and will not vary between alternatives.

FIGURE II-1

HOW MUCH OF THE WENATCHEE NATIONAL FOREST IS ACTUALLY AVAILABLE FOR CHANGING LAND ALLOCATIONS?

An even distribution of reasonable alternatives covering a broad range of possible actions were formulated by the Interdisciplinary Team. In formulating these alternatives, they were guided by several considerations. For example, the planning regulations 36 CFR 219.12(e) and (f) require a specific analytic process which includes an inspection of various minimum and maximum production levels and economic factors. In addition, the collection of alternatives must respond to public issues and include alternatives which reflect current and National programs such as the Resources Planning Act (RPA) program.

Some alternatives would manage the National Forest to maximize the production of priced commodities such as timber and range, while other alternatives would maximize the provision of unpriced amenities, such as dispersed recreation, wildlife, and scenery. One alternative (Alternative A/NFMA, "No Action") reflects current production levels, while another (Alternative B, RPA program) reflects the objectives of the Forest Service National program. One alternative, Alternative I, has an accelerated timber harvesting program ("departure"). From this broad range of alternatives, the Regional Forester has a basis for selecting the alternative (the Preferred Alternative) which comes nearest to maximizing the net benefits to the public while responding effectively to the Issues, Concerns, and Opportunities identified in Chapter I.

"Benchmarks" are presented and discussed in this chapter. Benchmarks are analytic bases from which the alternatives were developed. They were used to analyze certain relationships under special economic and resource production assumptions. Their character and use will be discussed in the next section.

B. OVERVIEW OF ALTERNATIVE DEVELOPMENT

The primary purpose of alternative development is to formulate a broad range of options as a basis for identifying the alternative that comes nearest to maximizing Net Public Benefits (NPB) (36 CFR 219.11(f)). An analytic process is used to develop alternatives that reflect a range of resource output and expenditure levels, distributed between the minimum and maximum resource potentials identified in the analysis process (36 CFR 219.12 (e) and (f)). Alternatives are formulated in a manner that facilitates the evaluation of a number of economic parameters, including effects on costs and benefits, present net value, employment and income, and analyses of trade-offs among alternatives. The collection of alternatives demonstrates different ways of responding to Issues, Concerns, and Opportunities.

By managing the forest resources in different ways, various objectives can be achieved which respond to the Issues, Concerns, and Opportunities. This differing management can vary by what, where, and when it is done. The result is a combination of management activities, management areas, and schedules which define a unique combination of resource outputs and environmental conditions for each alternative. The merits of an alternative are evaluated based upon the Net Public Benefit that the alternative achieves and how it responds to the public issues.

Present Net Value (PNV) is the quantitative component of Net Public Benefit. It is the discounted value of all priced benefits less all priced costs. Timber benefits and costs, quantitatively valued aspects of recreation, human use of wildlife and fisheries and range are included in the PNV calculations. Some values such as the preservation of old growth and roadless areas, the protection of spotted owls and rare plants, employment and local income, Retention and Partial Retention Visual Quality Objectives, returns to the federal and county governments, and the fostering of local social stability are not represented in the PNV figures. These and other values need to be taken into account in the development of alternatives that best respond to Issues, Concerns, and Opportunities.

Net Public Benefit reflects both quantified and non-quantified net benefits of the alternatives and represents the overall value to the nation of all outputs and positive effects (benefits) less all of the associated inputs and negative effects (costs) of producing priced and non-priced goods and services from National Forest lands (36 CFR 219.3). Net Public Benefit represents the sum of net priced outputs and the net value of non-priced outputs. Forest planning alternatives are formulated to examine different combinations of goods and services, both quantitatively and qualitatively valued, to find the mix that best maximizes Net Public Benefits while responding effectively to public issues.

The "No Action" Management Alternative A/NFMA is a key alternative in the planning process. This alternative projects the management direction found in existing land and resource plans. It serves as a basis (a yardstick) for measuring the environmental effects of implementing any alternatives compared to the existing situation. It also provides a means of comparing the ability of the alternatives to resolve the Issues, Concerns, and Opportunities in relationship to current management. The Alternative A/NFMA map depicts current land uses.

Forest unit plans, multiple use plans, and other current resource plans are the basis for the current management direction of the Alternative A/NFMA. The Forest's "No Action" Alternative is based upon the land uses designated in the Chelan Planning Unit FEIS dated April 28, 1976, the Kittitas Land Management Plan FEIS dated May 27, 1979, the Alpine Lakes Area Land Management Plan FEIS dated November 2, 1981, and the May 17, 1973, updates of the Tieton and Naches Ranger District Multiple Use plans plus other applicable multiple use resource plans and land use directives. Congressionally designated wildernesses such as those recently established by the Washington State Wilderness Act of June 29, 1984, supercede other land uses.

The "No Change" Alternative (Alternative NC) was developed differently than the other alternatives. It is based on the existing Timber Management (TM) Plans for the Wenatchee National Forest which are essentially single resource plans. The TM Plans emphasize production of the

timber resource. The land base that was used had different criteria for identifying lands suitable for timber harvest. Yield tables in the TM Plans are based on information that has since been updated.

By managing the Forest lands and resources in different ways, different objectives can be achieved which respond to different issues and produce various combinations of public benefits. Forest management can vary by what is done, where it is done, and when it is done. These different management activities, varying management areas, and differing schedules will result in varying resource outputs and environmental conditions in meeting the objectives of the alternatives.

An alternative is formulated by considering all of these factors:

- the capability of different areas on the Forest to produce various goods and services.
- the public's need or demand for different combinations of commodities and amenities.
- the management actions which are planned for different areas ("management prescriptions").
- the interrelationship of capabilities, management prescriptions, and schedules which result in resource outputs and environmental conditions which are consistent with the objectives of that alternative.

Management activities in all alternatives will be governed by Standards and Guidelines (Forest Plan, Chapter IV) as well as Best Management Practices, or "BMP's". Best Management Practices are specifically designed to protect water quality, as required by the Clean Water Act, and are a mitigation measure common to all alternatives. Appendix J, BMP's, describes the process and practices to protect water quality which were developed in response to public input.

1. DEMAND/SUPPLY ANALYSIS

The demand estimates in Table II-A reflect the future output/effect levels anticipated by several public agencies, including the Forest Service. These projections are discussed in several places in the FEIS, including Chapters III and IV. There is a further discussion of demand in Chapter II of the Forest Plan.

TABLE II-A
CURRENT OUTPUTS, AND SUPPLY POTENTIAL
BY RESOURCE OR ACTIVITIES

	UNITS	DECADE				
		Decade 1	Decade 2	Decade 3	Decade 4	Decade 5

2. FORPLAN

A large, computerized, mathematical simulation model of the Forest is used to keep track of all the factors in building an alternative and their interactions. This Forest Planning model, called FORPLAN, also assists in selecting that particular combination of lands, management prescriptions, and activity schedules that will best meet the objectives of an alternative.

FORPLAN, which is a "linear programming" model, is designed to simulate and to depict the effect of management on resources and environmental conditions on the Forest. It is also designed to find the "optimum" solution to a planning problem given the limited potential of the Forest to produce resources while maintaining desired environmental conditions. The model considers the effects of costs, budgets, and resource values.

The FORPLAN model is structured to achieve the targets and goals of each alternative with the greatest economic efficiency. This is done by selecting land units and prescriptions whose accumulative benefits will exceed the investment cost by the largest amount; i.e. maximize present net value. Present Net Value (PNV) is the current value of present and future monetary benefits after subtracting present and future monetary costs. The investment level or costs and benefits are an output of the FORPLAN solution rather than an input like the targets, goals, and prescription and land unit options. FORPLAN is thus able to predict some Forest-wide, cumulative, quantitative effects, including monetary costs and benefits under the conditions specified to achieve the objectives of a particular alternative.

The Forest Plan Interdisciplinary (ID) Team is directly involved with the design, operation and interpretation of the FORPLAN model. The land and resource base is stratified into land units or classes ("analysis areas"). Alternative management activities ("management prescriptions") are developed for each of these units according to the Team's instructions. The FORPLAN model examines this data and then assigns prescriptions to analysis areas and schedules activities. The ID Team must then assure that the model has correctly represented the objectives and constraints

assigned to the model, and that the results are feasible and implementable.

Many assumptions and generalizations are necessary to depict as large and complex an entity as the Wenatchee National Forest in a reasonably manageable and economical computer model. For example, timber stands found on the Forest consist of an almost infinite mix of plant species, tree sizes and stocking densities. They must be lumped into a fairly small group of "average" stands which can be modeled feasibly using current inventory data and modeling techniques.

Results of FORPLAN tend to suffice for the average situation but may not be applicable to every situation which can be found on the ground. These modeling limitations must be taken into account when interpreting FORPLAN results. FORPLAN is very useful in predicting relative differences between alternatives and in simulating broad impacts of alternative management strategies over time. The outputs and effects predicted by FORPLAN need to be tested on the ground over time through use of the Monitoring Plan (Forest Plan, Chapter V).

The process for formulating alternatives is one which involves considerable analysis of all resources and environmental conditions. It involves the examination of the National Forest under various management approaches designed to meet different goals and objectives. It is conducted by the Forest Plan Interdisciplinary Team, the Forest Management Team, Ranger District personnel, and interested members of the public.

Other analytic techniques were used to specify the parameters and the constraints required to use or supplement the FORPLAN model. After FORPLAN analysis, other analysis is conducted to aid in interpreting the results.

In some cases, the FORPLAN model will report that the Forest cannot be managed to meet a certain combination of objectives. In this case, the limitations of land and resources, impact on environmental quality, or the practical limits of budgets make the objectives infeasible. Then the Interdisciplinary Team must modify the objectives and make other "runs" of the computer model to find the particular combination of lands, activities,

and schedules which will best meet the goals of that alternative. Other analytic techniques are employed to validate a FORPLAN solution and to develop economic and other information about its implementation.

C. DESCRIPTION OF THE ANALYSIS PROCESS

Appendix B of this FEIS describes the entire analysis process in detail. Readers are encouraged to refer to that Appendix for technical information not presented in this chapter.

The analysis used in formulating the alternatives is guided by the planning regulations (36 CFR 219.12(e) and (f)).

The first steps in the analysis process begin with the inventory of the character, potentials, and limitations of different land areas of the Forest which have fairly uniform characteristics. These are identified as "analysis areas." The Interdisciplinary Team identified 130 analysis areas on the Wenatchee National Forest, ranging in size from 21 to 67,798 acres. These are the basic geographic units of alternatives. They are subdivisions of the Forest having similar characteristics of management cost and predicted response to Forest management activities.

Analysis areas on the Wenatchee National Forest typically were areas which were not contiguous. Analysis areas with a common management prescription are combined to form larger "management areas" in all implementable alternatives. In conjunction with the creation of analysis areas, the ID Team generated "management prescriptions" which apply to specific analysis areas and management areas. To direct on-the-ground management, standards and guidelines for management were written and/or incorporated from the Regional Guide. Mathematical estimates of their direct economic costs and resource yields were generated for use in the FORPLAN model.

The process of identifying and subsequently developing management prescriptions began with an Interdisciplinary Team review of the issues, concerns, and opportunities (ICO's). Prescriptions were then identified which would help

address those ICO's which were related to decisions regarding standards and guidelines, scheduling, or land allocations. There were other ICO's which were to be addressed through policy statements for which it was not appropriate to develop prescriptions.

Once the need and purpose for certain types of prescriptions was identified, goal statements for each management prescription were designed to respond to the questions raised by the ICO's. The Interdisciplinary Team then used professional judgment, evaluated existing policy, legislative direction, and research for guidance in developing multiple use management prescriptions. Regional Office and Ranger District personnel, representatives from other agencies, and interested members of the public participated in this process. The resulting management prescriptions then received thorough review, with some modification, by the Forest Management Team.

The resulting set of prescriptions represents a broad range of resource management emphases, practices, and capital investment levels. Forest-wide standards and guidelines were also developed by the Interdisciplinary Team and Management Team to cover practices common to all prescriptions and resource management situations that are Forest-wide in scope. For a complete description of the management prescription process, see Appendix B.

Prior to prescriptions being loaded into FORPLAN, an economic analysis of timber prescription feasibility and efficiencies, (Stage II Economic Analysis) was completed by Joan Krzak, the Forest economist at that time. This analysis disclosed that it was uneconomical to reforest non-stocked lands. It also concluded that all analysis areas that were to be used for FORPLAN modeling, which contained merchantable volume, were economic to harvest and reforest.

After making the first trial FORPLAN runs, it became apparent that the yield table that did not have a precommercial thin, but attempted to commercial thin, was not economical. At this point, that yield table (GF-2) was dropped from future consideration. See Appendix B for a complete discussion of the land allocation prescription process.

Management areas are portions of the Forest to which a set of management practices, standards, and guidelines apply. There is a range of 20 to 26 management areas used in developing the different alternatives. Management areas are identified on the maps for each alternative which accompanies this FEIS. The management areas are described immediately following Table II-1 and their acreages are shown in Table II-2.

The unit costs and values were not updated between the Draft and the Final in the FORPLAN model. In preparation of the Forest budget, some costs for wildlife and other resource areas were updated.

Having identified areas for analysis and management, and having prescribed the appropriate management practices and their mathematical expressions for use in the FORPLAN model, the Interdisciplinary Team proceeded with the following process of analysis in the formulation of alternatives.

The Timber Management Plans upon which the No Change Alternative is based were originally developed in 1963 and 1969. As stated previously, the TM Plans were not integrated resource plans. The Forest planning computer models were not used to model Alternative NC because of the differences in available information between it and the other alternatives. Because of this, there are outputs and effects from FORPLAN for the other alternatives that can't be derived with the same accuracy and reliability for the No Change Alternative.

The Chelan Unit Management Plan in 1976, the Kittitas Land Management Plan in 1979, and the District Multiple Use Plans, as modified by policies in the Forest Service Manual, provide new standards and management objectives which were used for on-the-ground management. These unit plan standards and management objectives are best represented in Alternative A/NFMA - No Action (Current Direction). However, the unit plan direction was not reconciled with the TM Plans pending completion of the Forest Plan. As a result, the timber potential yield estimated used in the TM Plans and in the No Change Alternative may not be feasible under the unit and multiple use plan allocations.

D. DEVELOPMENT AND IMPLICATION OF MANAGEMENT REQUIREMENTS

Management requirements (MR's) were developed in accordance with 36 CFR 219.27 to assure that the basic productivity of the land and water resources remains unimpaired. Selected MR's were tested to determine their effect on present net value, the first decade timber harvest level, and other selected outputs. The MR's tested were water quality/riparian areas, dispersion of openings created by harvesting, primary cavity excavators, and requirements for the marten, northern three-toed woodpecker, pileated woodpecker, and spotted owl.

The analysis of opportunity costs for meeting MR's was based on the Maximum Present Net Value (PNV) benchmark. Details on how the analysis was performed are provided in Appendix I. The effect that alternative means of meeting MR's had on key resource outputs is shown in the following table.

TABLE II-B

**OPPORTUNITY COSTS OF MEETING THE MANAGEMENT REQUIREMENTS
WITH SELECTED IMPLEMENTATION METHODS (MEANS)**

	FIRST DECADE ALLOWABLE SALE QUANTITY MMCF/YR (MMBF/YR)	CHANGE IN ALLOWABLE SALE QUANTITY 1/	PRESENT NET VALUE MM\$	CHANGE IN PRESENT NET VALUE
Maximum PNV Benchmark Displayed in the DEIS	29.9 (163 0)		2132	
Opportunity Cost--Approximate Change				
Opportunity Cost of Selected Timber Harvest Dispersion Implementation Methods	4.3 (23.4)	13.4%	25	1 2%
Opportunity Cost of Selected Mature Conifer Implementation Methods	0.9 (4.9)	3 0%	5	0 2%
Opportunity Cost of Selected Spotted Owl Implementation Methods	1.8 (9.8)	6.0%	9	0.4%
Opportunity Cost of Selected Water Quality/ Riparian Implementation Methods	1.8 (9.8)	6.0%	9	0 4%

MMCF/YR = Millions of cubic feet per year
MMBF/YR = Millions of board feet per year
MM\$ = Millions of dollars
1/ Percent change calculated on cubic foot basis

The results of the analysis show that the timber harvest dispersion MR has the highest opportunity costs. Costs for mature conifer and water quality/riparian MR's are the same, with the costs for spotted owls the least.

The opportunity costs of MR's when compared against one of the Forest Plan alternatives would be significantly less than the costs shown in the table. This is because the management practices necessary to meet other objectives of the plan alternatives may partially or fully meet the MR.

The timber harvest dispersion method was selected because it was the maximum rate at which regeneration cutting could occur without cutover openings being contiguous, assuming a checker-board harvesting model. A cutover area is no longer considered an "opening" when the trees reach a height of four and one-half feet. For the mature conifer habitat, the selected implementation method was that which was felt would maintain the viability of the selected wildlife species while having the least impact on timber harvest.

The results of the analysis of opportunity costs for the FEIS is substantially different from the analysis shown in the Wenatchee Supplement to the DEIS. This is because of the changes in requirements for mature conifer habitat and spotted owls. Direction for spotted owls was provided in the Forest Service Final Supplement to the EIS (SEIS) for an Amendment to the Pacific Northwest Regional Guide. The Record of Decision for the SEIS was not published until after the Wenatchee Supplement was released. Refer to Appendix I for further information.

Water quality/riparian implementation methods were selected to provide the most protection to the water resource with the least impact on timber harvest.

E. BENCHMARK ANALYSIS

Many of the first steps involved the creation of "benchmarks," and the inspection of their outputs, costs, and assumptions. Benchmarks are an assessment of the Forest's capability to produce goods and services, but lack consideration for likely budgets or the need to protect a full range of resource values. Benchmarks are similar to alternatives in that they are a combination of land capability, management practices, and schedules to achieve certain objectives. But unlike alternatives, they are usually not capable of actually being implemented, because of their narrow consideration of budget realities and management objectives. Benchmarks do provide significant information about the maximum biological and economic production opportunities. They also assist in evaluating the compatibilities or conflicts between market and nonmarket objectives, and define the range within which Forest management alternatives will be developed.

Changes in the alternative formulations and modeling parameters resulted in the benchmark data displayed in the DEIS being no longer comparable to the alternatives displayed in the FEIS. The benchmarks displayed have been updated to be comparable with the alternatives displayed in the FEIS. This update was done outside the FORPLAN model. (See Appendix B for further details).

Benchmark analyses were not conducted using the Alternative NC resource assumptions. These resource assumptions are not based upon the most recent scientific information.

Some benchmarks are economically based, while others indicate the maximum physical productivity of land for various resources. In these benchmark analyses, each option must include meeting management requirements of 36 CFR 219.27, such as protecting the productivity of the land, meeting minimum air and water quality standards, and maintaining wildlife viability. Benchmarks are also described further in Appendix B of the FEIS.

There are several benchmarks that are required by the planning regulations (36 CFR 219.12(e)) and National direction. They include:

1. MINIMUM LEVEL

This benchmark specifies the minimum level of management which would be needed to maintain the Wenatchee National Forest as part of the National Forest System.

2. MAXIMUM PRESENT NET VALUE BASED ON ESTABLISHED MARKET PRICE

This benchmark specifies the management of the Forest which will maximize the present net value of those outputs that have an established market price.

3. MAXIMUM PRESENT NET VALUE INCLUDING ASSIGNED VALUES

This benchmark specifies the management which will maximize the present net value of those outputs that have either an established market price or assigned monetary value.

4. CURRENT LEVEL

This benchmark specifies the management of the National Forest most likely to be implemented in the future if current direction is followed. This benchmark forms the basis for the "no action" alternative.

5. MAXIMUM RESOURCE LEVEL

Each of these benchmarks estimate the maximum capabilities of the Forest to provide a single resource output. There are maximum resource level benchmarks for Timber, Range, Wildlife, Fish, and Unroaded Recreation.

Other benchmark analysis is conducted to determine the effect of various management requirements and discretionary constraints. Analysis also assesses the effect of restricting timber harvest rotations to the culmination of mean annual increment (CMAI) and the impact of a nondeclining yield of timber harvest.

When a benchmark appears to offer a viable opportunity to respond to issues, concerns, and opportunities, further analysis is conducted to examine it as an alternative. Some benchmarks are the basis for alternatives, while others display too many environmental, fiscal, and practical problems in the analysis and are eliminated from *further study in detail*.

F. RANGE OF ALTERNATIVES

By inspecting the information generated by the benchmark analysis, and the parameters identified by the various benchmarks, the Interdisciplinary Team proceeded with constructing alternatives which could be implemented on the Forest.

The benchmarks presented in the previous section were one of the factors used to develop alternatives that represent a range of resource outputs for responding to the planning problems identified in Chapter I. Benchmarks can provide sideboards for the maximum the Forest can produce of various resource outputs. They help define for the decision-maker the amount of flexibility he has in making the decision; in other

words, the "decision space." A complete discussion of the decision space can be found in Appendix B. Forest Plan alternatives were not developed solely from benchmarks because the benchmarks were responsive to only one of several resource issues.

Alternatives were designed to span the benchmark range while meeting policy constraints such as the use of herbicides, different harvest systems (see Appendix H), and the SEIS Management Requirement Standards and Guidelines for the Spotted Owl (except Alternative NC). The standards and guidelines for riparian areas are also a constraint and were substantially modified from the Draft EIS in response to public comment.

Other constraints and prescriptions were also common or constant in all alternatives. These were necessary to meet planning requirements, existing laws or policies, or the objectives of prescriptions. Some areas on the Forest will not vary by alternative. These include Congressionally designated Wilderness, the two established Research Natural Areas, the Entiat Experimental Forest, and the Alpine Lakes Management Unit. Other constraints included the timber flow constraints, such as nondeclining flow (except for Alternative I); the harvest level of the last harvest period will be less than or equal to long-term sustained yield; and an ending inventory constraint. Additional constraints were included to meet management requirements such as the dispersion constraint and to provide for minimum viable wildlife populations. A complete discussion of the constraints common to all alternatives can be found in Appendix B.

Among the alternatives the ID team formulated are several that are required by regulations and National direction. The required alternatives are listed and briefly described here.

1. "NO CHANGE" ALTERNATIVE

This alternative was developed in response to decisions made regarding an appeal brought by the Northwest Forest Resources Council on May 19, 1986. The substance of the appeal was that a "true no action alternative representing current

management plans" was not included in Forest Plan EIS's. Although the appeal was denied, relief was granted in that Alternative NC was developed which is based on the existing Timber Management plans. As a result, it does not comply with all provisions of the National Forest Management Act of 1976 (NFMA) and the regulations promulgated by the Secretary of Agriculture to implement NFMA. The outputs of Alternative NC are similar to other alternatives and can therefore be used for comparison purposes.

2. CURRENT DIRECTION (NO ACTION)

This is the alternative of "No-Action" required by the Council on Environmental Quality (CEQ) regulations (40 CFR 1502.14) and the NFMA Planning Regulations (36 CFR 219.12(f)). This alternative would continue the management of the Forest as defined by existing direction in approved management plans. It assumes continuation of existing policies, standards, and guidelines, current budget levels updated for changing costs over time; and, to the extent possible, production of current levels and mixes of resource outputs.

Alternative A/NFMA is the Current Direction Alternative (or the "No-Action" Alternative) in this FEIS.

3. EMPHASIS ON THE CURRENT RPA PROGRAM

This alternative determines how the Current (1980) RPA program distributed to the Forests through the Regional Guide could best be implemented.

Alternative B is the current RPA program alternative in this FEIS.

4. EMPHASIS ON MARKET OPPORTUNITIES

This alternative has an emphasis on outputs that have an established market price (timber, live-stock range, forage, commercial fish, developed recreation opportunities, and minerals). Management for other resources will be at economically and environmentally feasible levels consistent with the emphasis on market-oriented outputs.

Alternative D is the alternative in this FEIS which emphasizes market opportunities.

5. EMPHASIS ON NON-MARKET OPPORTUNITIES

This alternative has an emphasis on water, fish, scenery, wildlife, recreation and other amenity values (the maximum amount of the roadless inventory would be allocated to a roadless management emphasis). Management for other resources will be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

Alternative E is the alternative in the FEIS which emphasizes amenity values.

6. EMPHASIS ON DISPERSED UNROADED RECREATION AND INTENSIFIED MANAGEMENT

This alternative allocates a large portion of the roadless areas on the Forest to dispersed unroaded recreation while increasing commodity production on those areas already roaded. Its purpose is to offset the economic effects of not beginning commodity production in roadless areas. It also attempts to reduce potential cumulative effects of management activities on National Forest and adjacent forest lands.

Alternative G is the alternative in this FEIS which best emphasizes dispersed unroaded recreation and intensified management

7. DEPARTURE ALTERNATIVE

One alternative is a "departure" alternative. It has the same land allocation and resource management prescriptions as Alternative C. However, the timber harvest schedule has been modified from the base sale schedule which would result in a non-declining flow of timber that never exceeds the long-term sustained yield capacity of the Forest. In most cases, management under a departure alternative results in higher volumes of timber harvested in the near future and lower volumes of timber available in the intermediate future. The ability of the Forest to produce timber in the long run is no less than that of the alternative upon which the departure was based.

Alternative I is the departure alternative in this FEIS.

8. OTHER ALTERNATIVES

Additional alternatives were necessary to respond to the full range of public issues, management concerns, and resource use and development opportunities. These were formulated to reflect a broad range of resource outputs and expenditure levels. Additional alternatives were also formulated to respond to 36 CFR 219.12a(f)(1) which requires alternatives to "be distributed between the minimum resources potential and the maximum resource potential" to display the "full range" of outputs that a Forest could produce.

A new alternative, Alternative J, was added between the Draft and Final EIS in response to public comment. It was developed by representatives of timber industry, and was referred to during the public comment period as the "Essential Alternative."

9. THE PREFERRED ALTERNATIVE

The Forest Service Preferred Alternative has been identified. The selection of the Preferred Alternative was made only after careful comparison of all the alternatives on the basis of their resource outputs, environmental effects, implementation costs, and the trade-offs between them. The Preferred Alternative is that alternative

which is selected from all those formulated as the one which best maximizes the net public benefits while responding effectively to the issues, concerns and opportunities. After the Forest Supervisor reviewed the Interdisciplinary Team's evaluation, and after the Regional Forester and his staff had reviewed the alternatives, this alternative was selected as the preferred alternative in this Final EIS.

Alternative C is the Preferred Alternative.

G. ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Many alternatives were considered to address all of the issues, concerns, and opportunities which have been expressed and to meet directions from various management levels within the Agency. Eleven alternatives were selected to be studied in detail. An alternative was received from Earth First! but was not considered further because it was not a legal alternative. The remainder of those alternatives considered are described below with the rationale for eliminating them from further study.

1. VARIATIONS TO THE LAND ALLOCATIONS AND MANAGEMENT OF THE ALPINE LAKES MANAGEMENT AREAS

The Alpine Lakes Area Land Management Plan (11/2/81) was congressionally mandated through the Alpine Lakes Area Management Act of 1976. This Plan was implemented early in 1982 following a tremendous amount of public involvement. This plan was also developed under an interdisciplinary process similar to the NFMA regulations being used in the Forest Plan. The area has been managed under the above plan for approximately seven years. To date, neither the Forest Service nor the public has identified any major problems with the allocation or management of that plan. In good faith to those members of the public who helped develop that plan, the Forest Plan proposes that the land allocations and management as presented in the Alpine Lakes Area Land Management Plan be held constant in all alterna-

tives. Both the Wenatchee and the Mount Baker-Snoqualmie Forests are in agreement with this proposal which will allow that plan to stand the test of time. Problems which surface could be handled administratively or when the Forest Plan is revised.

It is felt that this proposal is in accord with 36 CFR Part 219.2(b) of the NFMA planning regulations which states:

“219.2(b) If, in a particular case, special area authorities require the preparation of a separate special area plan, the direction in any such plan may be incorporated without modification in plans prepared under this subpart.”

2. A VERSION OF THE CURRENT DIRECTION ALTERNATIVE WHICH DEPICTED AN EARLIER VISUAL QUALITY OBJECTIVE CLASSIFICATION

Several years ago, when the Visual Quality Objective (VQO) concept was initiated, the Forest was mapped to the various VQO classifications. There was a sincere effort to meet these objectives whenever possible, but experience revealed that the initial mapping was not always the most appropriate for the specific site. As this alternative was being developed, it became evident that the management of the Forest did not always meet the original visual quality objectives. Therefore, no further analysis was conducted on this alternative.

The VQO's, as presented in Alternative A/ NFMA are the result of a completely new VQO inventory which depicts the present visual management of the Forest.

3. WATER CONSERVATION ALTERNATIVE

Representatives of the Friends of the Earth submitted a narrative description of an alternative which would emphasize the management of the portion of the Yakima River Drainage Watershed on the Wenatchee National Forest to maximize

water conservation for fisheries and irrigation benefits. Management for other resources would be at economically and environmentally feasible levels consistent with the emphasis on water conservation values. This alternative also strives to eliminate or mitigate potential adverse cumulative effects on soil, water, recreation and visual resources.

Alternative E, as discussed later in this chapter, has a goal which is very similar to the above alternative. It is applicable to the entire Forest.

4. DEPARTURE ON ALTERNATIVE C TO REACH RPA '80

Alternative B, the RPA Alternative, was originally formulated as a departure alternative based on Alternative C. The departure met the RPA timber target in the first decade but not in subsequent decades. For this reason, the above mentioned departure version was not considered in greater detail.

5. ALTERNATIVE G WITH VARIOUS HARVEST LEVELS

Four variations of Alternative G were considered but eliminated from detailed study. The basic land allocations for these variations were identical to that of Alternative G. The timber harvest schedule varied from the level which maximized present net value to the level which maximized timber volume, including three intermediate levels. The FEIS displays Alternative G under a maximize present net value objective function.

6. ALTERNATIVE I - VARIOUS DEPARTURES

Six variations of Alternative I were examined. All variations used Alternative C as a base, but had different timber harvest schedules. One variation was selected as best meeting the intention of the alternative to start at the current level of timber and gradually phase into the level of Alternative C. The other variations were not considered further.

H. ALTERNATIVES CONSIDERED IN DETAIL

The alternatives considered in detail are alternate ways of managing the land and resources of the Wenatchee National Forest. They are a combination of land uses, management practices, and activity schedules, which result in a unique combination of resource outputs, land uses, and environmental conditions.

Formulated through an analysis process that explored a wide array of possibilities shown in the benchmarks and here in the required alternatives, these alternatives together present a broad range of reasonable management options.

Each alternative has goals and output objectives. These are designed, with the exception of Alternative NC, to respond to public issues and management concerns. Table II-1 presents the response of each alternative to all the issues and concerns. The planning problems listed in Chapter I were used to develop the goals for each alternative.

Each alternative, except Alternative NC, distributes the lands of the Forest to different management areas. The acreages in the different management areas vary from one alternative to another. These acreages are presented in Table II-2. A description of the management areas and the goals of land and resource management in them is presented later in this chapter in the discussion preceding Table II-2. The location of the management areas for each alternative, except Alternative NC, are shown on the maps which accompany this FEIS.

The management areas would be managed according to management standards and guidelines. One of the principal functions of these standards and guidelines is to assure that potentially adverse environmental effects are mitigated and/or avoided. For example, Appendix J Best Management Practices is an example of mitigation measures for water quality. Other examples of mitigation measures common to all alternatives include: the use of Forest Service manuals and handbook guides; the use of visual management practices in harvest activities to maintain a natural appearing setting; the use of aerial or full suspen-

sion logging systems to protect cultural resources, the establishment and monitoring of limits of acceptable change for reducing impacts in Wilderness areas; the replanting of harvest units with mixed tree species to minimize tendencies towards monoculture; the use of fertilizer to mitigate for management practices which reduce productivity; the adjustment of utilization standards for grazing to provide for plant needs, and soil and water protection; more complete use of wood residue to mitigate effects of prescribed fire; and the use of road closures for reducing impacts on wildlife and some types of recreation. (See FEIS Chapter IV for additional mitigation measures by environmental component).

Some of these standards and guidelines were developed by the Planning Interdisciplinary Team specifically to respond to environmental conditions on the Wenatchee National Forest, and others are adopted from the standards and guidelines in the Regional Guide. The standards and guidelines which apply to all alternatives are found in Chapter IV of the Forest Plan.

The management of the Forest according to the different alternatives will result in various land uses, resource outputs, and environmental effects. Some differences represent the specific objectives of the alternative. All of the significant land uses, environmental effects, and resource outputs are presented by alternative and by time period in Tables II-3a and Table II-3b. Table II-3a presents those uses, effects, and outputs which are quantified; Table II-3b, those which are qualitative.

The relationships of resource outputs and environmental effects are discussed in Chapter IV, Environmental Consequences. There are also summaries of the outputs and effects there. However, the most detailed reporting of each alternative's land uses, resource outputs, time frames, costs, benefits, availability of acres for management and environmental conditions are here in Chapter II. This placement of the effects of the alternatives is all designed to facilitate the comparison of the alternatives. It allows comparison of several types of outputs and effects at one time.

1. DESCRIPTION OF THE ALTERNATIVES CONSIDERED IN DETAIL

The following alternatives were selected for detailed study. They represent a broad range within the decision space identified by the benchmarks. For a complete discussion of the decision space, see Appendix B.

THE NO CHANGE ALTERNATIVE (ALTERNATIVE NC)

The No Change Alternative was developed in response to decisions made regarding appeal number 1588 brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by then Regional Forester James F. Torrence to "require inclusion of minimum management requirements (MR's) in the Current Direction Alternative for each Forest Plan." Although the appeal was denied, an alternative named "No Change" was developed to represent the existing Timber Management plans and consequently does not comply with all provisions of the National Forest Management Act of 1976 (NFMA) and regulations (36 CFR 219) promulgated by the Secretary of Agriculture to implement NFMA.

Alternative NC displays the objectives, outputs, and effects of the Wenatchee National Forest's Timber Management (TM) Plans so that they can be compared with the other alternatives. However, since the development of the TM plans, new inventories, assumptions about resource interrelationships, and new methods for predicting timber growth and yields have been developed. Therefore, a reviewer should be aware that information

THE NO CHANGE ALTERNATIVE (ALTERNATIVE NC)

provided for Alternative NC is frequently based on outdated inventories and yield tables and is not always comparable to information provided for the other alternatives.

RECREATION SETTING

--Developed Recreation

Alternative NC provides the same allocation and opportunities for developed recreation as Alternative A/NFMA. The emphasis would be on bringing selected sites up to full service standards. Only those sites which have a history of heavy use, or where it is possible to convert all sites in a single drainage to full service sites, would be considered. Other popular sites would be maintained with very little improvement to existing facilities. Some expansion of existing full service sites would occur.

There would be some opportunity to improve and/or establish overlooks and scenic vistas in new roaded areas.

Ski areas that have current master plans and are considering expansion are: Mission Ridge, White Pass, and Stevens Pass.

--Dispersed Recreation

Based on allocations contained in the timber management plans, 8.0 percent of the Forest would provide unroaded recreation opportunities outside of established Wilderness, with 1.7 percent of the Forest in an unroaded allocation. The additional 6.3 percent are unsuitable lands not scheduled for timber harvest. The timber management plans do not contain Recreation Opportunity Spectrum (ROS) classifications, however, there would be approximately 175,015 unroaded acres in a Semi-Primitive setting. In addition, there will be 1,148,131 acres (53 percent of the Forest) providing roaded recreation.

Two of the inventoried roadless areas outside of the Alpine Lakes Management Area would have a substantial portion of their area in a roadless management character. These are shown below:

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS	ACRES TO BE ROADED
Myrtle Lake	10,918	8,967	1,951
Entiat	71,254	27,430	43,824

An additional 138,678 acres would remain unroaded in scattered high country blocks classified as unsuitable for timber harvest. These scattered blocks could not be specifically identified by geographic area from the data contained in the timber management plans.

There would be a reduction of approximately 525 miles of trail resulting from timber harvest and road construction. Trailhead locations would also be moved as a result. The miles of trail available to motorized use by land allocation or due to administrative closures are:

ALLOCATION	MILES OPEN TO MOTORIZED USE	MILES CLOSED TO MOTORIZED USE
Wilderness	---	1,188.0
Unroaded ^{1/}	268.0	94.4
Roaded	481.8	---
Administratively closed	---	367.4

^{1/} The timber management plans did not distinguish between unroaded motorized and unroaded non-motorized.

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The Tumwater Botanical Area is provided for in the timber management plans and would be protected.

WILD, SCENIC, AND RECREATIONAL RIVERS

There are no rivers recommended for designation under the Wild and Scenic Rivers Act. Corridors of potentially eligible rivers would be open to a range of management activities, some of which could noticeably alter the values that contribute to their eligibility.

SCENERY

The timber management plans contained Landscape Management Units (LMU's) where harvest levels were expected to approximate gross growth. For example, if a unit grew at a rate of 3 million board feet (MMBF) per year, the harvest level in that same unit would also be 3 MMBF.

The acreage in these LMU's allowed for protection of the foreground and partial protection of the middleground viewing area along all major travel viewsheds. Background areas within the viewsheds would have no reduction in harvest level for scenery protection. This would result in a reduction in scenic qualities throughout much of the Forest including portals to wilderness.

Visual quality objectives would remain at a high level along the immediate foreground of all major interstate scenic highway travel routes, and most major wilderness portals that are in contiguous Forest Service lands.

Some wilderness and main transportation corridors will not maintain scenic qualities. Unnatural landscape patterns would occur in almost all major viewsheds.

Roaded areas, including all of the Forest's 34 inventoried viewsheds, will be heavily altered.

In this alternative, a buffer strip of trees 200 feet along both sides of the travel route would be left natural appearing. However, the viewshed beyond the 200 foot strip will be heavily altered.

The general visual impression of the majority of the Forest would be one of a heavily altered landscape with contrasting openings, visible logging roads, and block-cut patterns.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

Over 80 percent of the known cultural resources would be within management area designations that may create a potentially moderate to high level of impact (about 60 percent would be within management areas that could be considered to have a high level of impact). These would require mitigation measures or frequent project modification. There might be substantial modification of the visual settings around several significant sites. Loss of non-significant sites might be high.

A high number of acres would be inventoried for cultural resources (approximately 788,000 acres over the planning period in support of the timber program alone), but the ways in which identified sites could be managed and interpreted in place might be constrained.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest. Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 85 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

Habitat for sensitive species will not increase.

Under this alternative, big game numbers would achieve a high level now and will decrease to the lowest levels of all alternatives. This results from many acres of timber harvest in a short time creating an abundance of forage and near optimum conditions. As the timber harvest continues over time, thermal cover becomes the limiting factor. After all stands have been harvested that create significant increases in forage, forage again becomes the limiting factor. This trend is predicted for both summer and winter habitat.

The implementation of the existing primary cavity excavators direction did not consider the State safety requirements for working in the vicinity of dead trees. This problem has reduced habitat for a number of years and the accumulation of the loss of habitat may result in population levels below 40 percent at some time in the future. As direction problems are resolved, the population will return to the 40 percent level or higher.

This is the only alternative that decreases riparian habitat in the future.

Alternative NC provides the lowest level for recreation use of wildlife of all alternatives due to reduced wildlife population.

There is no spotted owl or mature habitat (marten, three-toed, and pileated woodpecker) network in this alternative. Therefore, the habitat for these species is decreasing faster and to lower levels than other alternatives.

FISHERIES

Riparian habitat protection under this alternative would consist of actions to meet the minimum requirement of the Washington State Forest Practice Rules. Riparian standards applicable to other alternatives to maintain current and long-term fish habitat would not be implemented. Fish outputs would be expected to be maintained at current levels, changing as downstream problems such as passage at mainstream Columbia River Dams are corrected. There is greater risk that fish habitat capability would decrease over time due to the lack of riparian habitat protection and management standards.

RANGE

Permitted livestock grazing would increase slightly in the second decade and then decrease in the third through fifth decades due to constrained budgets. Permitted use in the first decade would be expected to average 23,000 animal unit months (AUM's), 23,000 AUM's in the second decade, and 20,000 AUM's by the fifth decade. Demand for sheep grazing would be met in all decades but demand for cattle grazing would exceed permitted use at the end of the first decade. Actual permitted use will never approach the production potential of 38,000 AUM's

OLD GROWTH

This alternative would have approximately 148,500 acres of old growth in wilderness and 11,200 acres in areas excluded from harvest by law and policy (but outside wilderness). There are an estimated 159,100 acres of old growth outside wilderness for a current estimate of 318,800 acres of old growth on the Wenatchee National Forest. By the 5th decade, there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce 32.4 million (MM) cubic feet (176.8 MM board feet) per year for the first five decades. This would also be the long-term sustained yield provided no land use constraints were imposed that were not in the original TM plans.

The timber yields in Alternative NC were computed differently than in the other alternatives. For example, the Wenatchee Working Circle plan (Chelan, Entiat, Lake Wenatchee, Leavenworth, and Cle Elum Ranger Districts) had no specific guidance on acres of thinning to be accomplished.

The Naches-Tieton Working Circle TM plan (Naches Ranger District) has a temporary inflation of 14.0 MMBF which is included in the Forest total of 176.8 MMBF. This is based on 15 year cutting entries into the stand and harvesting of extensive mortality salvage volume. The actual potential yield would then become 162.8 MMBF for the entire Forest. Yield projections for this Working Circle included a successful overwood removal to release existing pole stands in most two-storied stands.

An average of 3,944 acres per year would be clearcut, 3,928 acres would be shelterwood cut, and 1,896 acres would be partial cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increase for the first decade of 24,400 acre-feet, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The overall trend is for the amount of delivered sediment from management activity areas to increase over time. Delivered sediment levels from these lands for the first decade would be about 94,900 tons per year above the background level of 930,500 tons per year. The No Change Alternative would increase the amount of water flowing off of the forest and will also increase the amount of delivered sediment. This is due to the increased amount of clearcutting and increased mileage of roads, as well as the lack of land use constraints in Alternative NC.

MINERALS

The area withdrawn as wilderness (841,034 acres) would not change in any of the alternatives including the No Change Alternative, but the additional area to be withdrawn and the area to be managed as highly sensitive, does vary some. In addition to wilderness withdrawals, this alternative would result in the withdrawal of 276 additional acres as research natural areas. This is a very small percentage of the total Forest acres. A total of 77,721 acres would be in allocations which are considered to be "highly" sensitive toward mineral related activities. This is less than four percent of the total Forest acres. Since the timber management plans do not provide sufficient detail, the effect Alternative NC would have relative to the locatable and leasable mineral potential areas cannot be accurately presented.

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

About 25 small hydroelectric proposals are pending. Three of these are applications to the Federal Energy Regulatory Commission for licenses to construct and operate hydroelectric power facilities. The remaining proposals are still pending.

ROADS

Proposed new road construction for the first decade is 670 miles of new local road and 300 miles reconstruction. Road densities beyond the first 10 years are a FORPLAN output and cannot be estimated. The more important proposed road construction and reconstruction is listed on the Road Construction/Reconstruction Table IV-26 in Chapter IV of the FEIS.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. Lightning fires in wilderness would be carefully monitored and allowed to play their natural role unless there is a threat to life, property, or important natural resources. If such a threat exists, the fire will be extinguished. Human caused fires occurring in wilderness would be put out. Prescribed fire would be used as a management tool for reduction of activity generated fuels (slash) and for maintenance and improvement of other resources.

SOCIAL/ECONOMIC

An annual budget of 17.6 million dollars would be required for implementation of the No Change Alternative. Revenues from Forest products would return 15.2 million dollars to the U.S. Treasury; 3.8 million dollars would be returned to local governments. Employment would increase by 378 jobs over base year levels with income increasing by 12.1 million dollars.

Present Net Value cannot be computed for this alternative.

NO CHANGE ALTERNATIVE
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual recreation capacity	Rec. Visitor Days	1/
<u>Roadless Management</u> (RE-2a, RN-1, SI-2)		
	Acres	37,717
<u>Wild and Scenic Rivers</u>		
	Miles	0
<u>Water Quality and Quantity</u>		
Water yield increase	Acre feet	24,400
Sediment increase index	Tons/year	94,900
<u>Old-growth</u>		
	Acres	1/
<u>Wildlife and Fish</u>		
Wildlife habitat management	Acres	0
Anadromous fish commercial harvest	Pounds	1/
<u>Landscape Management Units</u>

Grazing capacity	Animal Unit Months	38,000
Permitted grazing	Animal Unit Months	23,000
Area of suitable grazing land	Acres	1/
<u>Social/Economic</u>		
Present Net Value	Million Dollars	1/
Annual cost to the Federal Government	Million Dollars	17.6
Annual revenues to the Federal Government	Million Dollars	15.2
Annual returns to Local Governments 3/	Million Dollars	3.8
Change in employment 3/	Number of Jobs	+378
Change in income 3/	Million Dollars	+12.1

1/ The Timber Management (TM) Plans, upon which the No Change Alternative is based, are not integrated resource plans. As a result, all the resource uses and outputs are not addressed. The missing information in this table cannot be reasonably estimated because the original plan was based on yield tables and resource relationships which do not reflect the latest scientific techniques and information.

2/ The potential yield includes a 2.6 MMCF (14.0 MMBF) temporary inflation of the cut on the Naches Ranger District. Potential yield figures are not directly comparable to the ASQ of other alternatives.

3/ Employment and income figures are based on volumes harvested, not potential yield or volumes sold.

ALTERNATIVE A/NFMA

This is the No Action Alternative. It was formulated to maintain the current management direction for the Forest. Sources of that direction were the Alpine Lakes Management Plan, the Chelan and Kittitas Unit Plans, and the Ranger District multiple use plans. Alternative A/NFMA portrays how these plans would influence the flow of goods and services over the life of this plan (10-15 years) based upon the use of current National Forest Management Act of 1976 (NFMA) planning data. It also approximates the current budget.

This alternative has been corrected from the DEIS version (Alternative A) and meets all NFMA requirements as explained in the "Correction and Supplemental Information" which was included with the Reviewer's Guide when the DEIS was mailed to the public. The Supplement to the DEIS also contained corrected information and displayed this alternative as Alternative A/NFMA. Essentially the difference between Alternative A in the original DEIS and Alternative A/NFMA, is that this alternative now meets all of the management requirements including protection of habitat for wildlife dependent upon old-growth and mature habitat types.

One of the features of this alternative is that it contains significantly fewer acres of EW-1 (Key Deer and Elk Habitat) than any of the other alternatives except the No Change Alternative. The reason for this is that most of the existing plans did not contain specific allocations for key big game habitat.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and "dedicating" old growth spotted owl habitat areas rather than "managing".
- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.

RECREATION SETTING

--Developed Recreation

The emphasis will be on bringing selected sites up to full service standards. Only those sites which have a history of heavy use, or where it is possible to convert all sites in a single drainage to full service sites, will be considered. Other popular sites will be maintained with very little improvement to existing facilities. Some expansion of existing full service sites will occur.

There will be some opportunity to improve and/or establish overlooks and scenic vistas in new roaded areas.

Ski areas that have current master plans and are considering expansion are: Mission Ridge, White Pass, and Stevens Pass.

--Dispersed Recreation

By the second decade, 12 percent of the Forest will provide unroaded recreation opportunities outside wilderness. This includes 8,371 acres primitive, 57,158 acres Semi-Primitive, Non-Motorized, and 183,825 acres Semi-Primitive, Motorized Recreation Opportunity Spectrums (ROS).

In addition, there will be 49 percent of the Forest providing roaded recreation or 1,066,012 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrums combined.

Fifteen of the 23 inventoried roadless areas will have a substantial portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	10,918	0
Rock Creek	32,924	17,935	14,989
Twin Lakes	22,048	13,717	8,331
Canyon Creek	9,158	0	9,158
Heather Lake	11,067	1,526	9,541
Chelan	71,063	59,806	11,257
Entiat	71,254	19,144	52,110
Stormy	32,500	0	32,500
Slide Ridge	10,091	0	10,091
Devil's Gulch	25,186	9,222	15,964
Taneum	25,122	6,296	18,826
Manastash	8,798	4,070	4,728
Norse Peak Adj	11,300	2,650	8,650
Quartz	8,756	64	8,692
Naneum	6,911	21	6,890
Lion Rock	4,834	0	4,834
William O. Douglas Adj.	22,938	784	22,154
Blue Slide	18,571	0	18,571
Goat Rocks Adj	7,357	5,597	1,760
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 4,388 acres of dedicated old growth that fall within roadless allocations.

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1,188
Unroaded Non-motorized	--	94.4
Unroaded Motorized	235.1	---
Roaded Motorized	944.7	---
Administratively Closed	--	367.4

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>
Tumwater	Teanaway Nason Ridge Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

The White, Chiwawa and Wenatchee Rivers are recommended for designation under the Wild and Scenic Rivers Act. The proposed classifications are as follows:

River	Recommended Classification	Miles	Segment
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch.
	Recreational	12.0	Above Tall Timbers Ranch to Lake Wenatchee
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary.
	Recreational	24.0	Glacier Peak Wilderness boundary to Goose Creek.
	Recreational	6.0	Goose Creek to confluence with Wenatchee River.
Wenatchee	Recreational	21.0	Lake Wenatchee to Tumwater Campground
	Recreational	7.0	Tumwater Campground to Forest boundary.

The characteristics contributing to their eligibility will be protected until Congress formally determines the status of these rivers. Other eligible rivers on the Forest will not be recommended for inclusion in the Wild and Scenic Rivers System, but the corridors will be managed for Scenic Travel, with a visual quality objective of Retention. See Appendix E for a complete description of the Wild and Scenic Rivers analysis process.

SCENERY

All major interstate scenic highway viewsheds and the Alpine Lakes Management Unit would retain natural or slightly altered conditions.

All major portals to wilderness would retain a near natural appearance. The natural appearance of the Forest as viewed from Forest roads would be reduced but a natural appearance would dominate the majority of the landscape.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-Wide Standards and Guidelines would direct future management decisions regarding significant cultural resources.

A majority of the known cultural resources (roughly 76 percent) would be within management area designations that may create a potentially moderate to high level of impact. These would require mitigation. Visual settings around some significant sites might experience modification apparent to the viewer. Opportunities would be good to enhance several significant historic sites through treatment of the adjacent vegetation in conjunction with the Forest timber management program.

There would be a high number of acres inventoried for cultural resources (approximately 592,000 acres over the planning period). Accessibility to cultural sites managed for interpretation would be very good.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 58 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

Alternative A/NFMA maintains lower levels of habitat for mature and old growth species than some other alternatives.

Deer and elk summer habitat is reduced a small amount with a moderate reduction in their wintering habitat.

Primary cavity excavator habitat is reduced to about the average of most alternatives.

Riparian habitat increases moderately.

This alternative is in the middle of the range of providing for recreation use of wildlife.

State wildlife objectives would be met for mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 151,000 acres of suitable spotted owl habitat in lands that are unsuitable for timber management, or in allocations that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 16,430 acres originally allocated to full timber yield prescriptions, and 41,955 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in a small increase in both anadromous and resident fish habitat capability through the life of the Plan. In the second decade, the numbers of catchable cut-throat trout are estimated to increase from a current level of 200,000 fish to approximately 202,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase slightly from 1.348 million to 1.354 million smolts and 172,000 smolts to 173,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is expected to remain constant at current levels through the life of the Plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices which will maintain current habitat capability and should allow fairly natural stream processes to operate, resulting in improving trends in habitat capability. Further small increases are expected due to implementation of habitat improvement program. It is estimated that approximately \$37,000 of the annual habitat improvement program will be funded through appropriated monies and \$25,000 through KV. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off the Forest. This alternative, however, will provide habitat at current levels with an improving trend and thus is consistent with the objective to improve anadromous fish runs in the drainage.

Resident trout habitat will also be maintained so opportunities for sport fishing will be provided at current levels with a relatively small increase in the availability of catchable resident trout.

RANGE

Permitted livestock grazing would increase slightly in the second decade and then decrease in the third through fifth decades due to constrained budgets. Permitted use in the first decade is expected to average 23,000 animal unit months (AUM's), 23,000 AUM's in the second decade, and 20,000 AUM's by the fifth decade. Demand for sheep grazing would be met in all decades but demand for cattle grazing would exceed permitted use at the end of the first decade. Actual permitted use will not exceed the total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 55,863 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 22,854 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 91,567 acres of old growth. By the 5th decade, there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce on Allowable Sale Quantity of 21.8 million (MM) cubic feet (121.4 MM board feet) per year and a Timber Sale Programmed Quantity of 23.4 MM cubic feet (130.3 MMBF) for the first five decades. The long-term sustained yield for this alternative is

27.7 MM cubic feet based on 591,794 acres of suitable timber lands. This compares to the past decade average annual volume sold of 187.5 MMBF and an average annual volume harvested of 166.0 MMBF.

A wide range of timber intensities were selected for this alternative ranging from GF-1 (high level of timber investment) to GF-6 in General Forest (GF) Management Areas. Intensive management with control of tree spacing is planned on 23% of GF acres.

An average of 2,590 acres per year will be clearcut, 2,539 acres will be shelterwood cut, and 2,564 acres will be selective cut.

Clearcutting is optimal and proposed where mistletoe and root rot are common. Mistletoe and/or root rot are estimated to affect 50-55 percent of the Forest acres. (Hadfield, 1982) Clearcutting is also optimal where shallow rooted species such as western hemlock and grand fir are subject to extensive blowdown. Partial cutting, or shelterwoods, in previously dense stands often result in windthrow during wet soil periods or heavy wet snowfalls.

Pesticide use will be allowed if necessary to control insects, rodents, and unwanted weed vegetation under all alternatives. The amount of use has been very inconsistent in the past. Insecticides are not used to any extent except for minor campground fly control in most years. However, in 1976, 1977, and 1978 aerial spraying of Fenituthion, Malathion, and Sevin-4-oil covered 210,300 acres of the Wenatchee Forest to control the spruce budworm. *Bacillus Thuringiensis* (BT) was sprayed on approximately 50,000 acres in 1987. Since treatment, no reoccurrence of epidemic populations have been recorded.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber

harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 13,800, 18,900 and 21,600 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades the activity related delivered sediment will be approximately 69,200 tons per year. By the end of the third decade, most of the roads will have been built so that the forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by about forty-four percent, therefore soil losses produced by management activities in the fifth decade will be approximately 38,800 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 1,717 additional acres from mineral entry, which is less than 1 percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 411,199 acres, or 19 percent of the total Forest acres. The following figure shows how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWAL	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	22,960 acres or 19%	36,782 acres or 31%
Area classified prospectively valuable for oil and gas	0 acres or 0%	32,246 acres or 15%	173,608 acres or 82%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	55,269 acres or 9.2%	42,315 acres or 11%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	140,070 acres or 26%	284,718 acres or 54%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

About 25 small hydroelectric proposals are pending. Three of these are applications to the Federal Energy Regulatory Commission for licenses to construct and operate hydroelectric power facilities.

ROADS

The implementation of Alternative A/NFMA would require the construction of approximately 1,480 miles of additional road. Some 748 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 20 years. In addition to the roads currently open, it is expected that 20% of the new roads would be opened to public use by high clearance vehicles.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. Lightning fires in wilderness would be carefully monitored and allowed to play their natural role unless there is a threat to life, property, or important natural resources. If such a threat exists, the fire will be extinguished. Human caused fires occurring in wilderness would be put out. Prescribed fire would be used as a management tool for reduction of activity fuels (slash) and for maintenance and improvement of other resources.

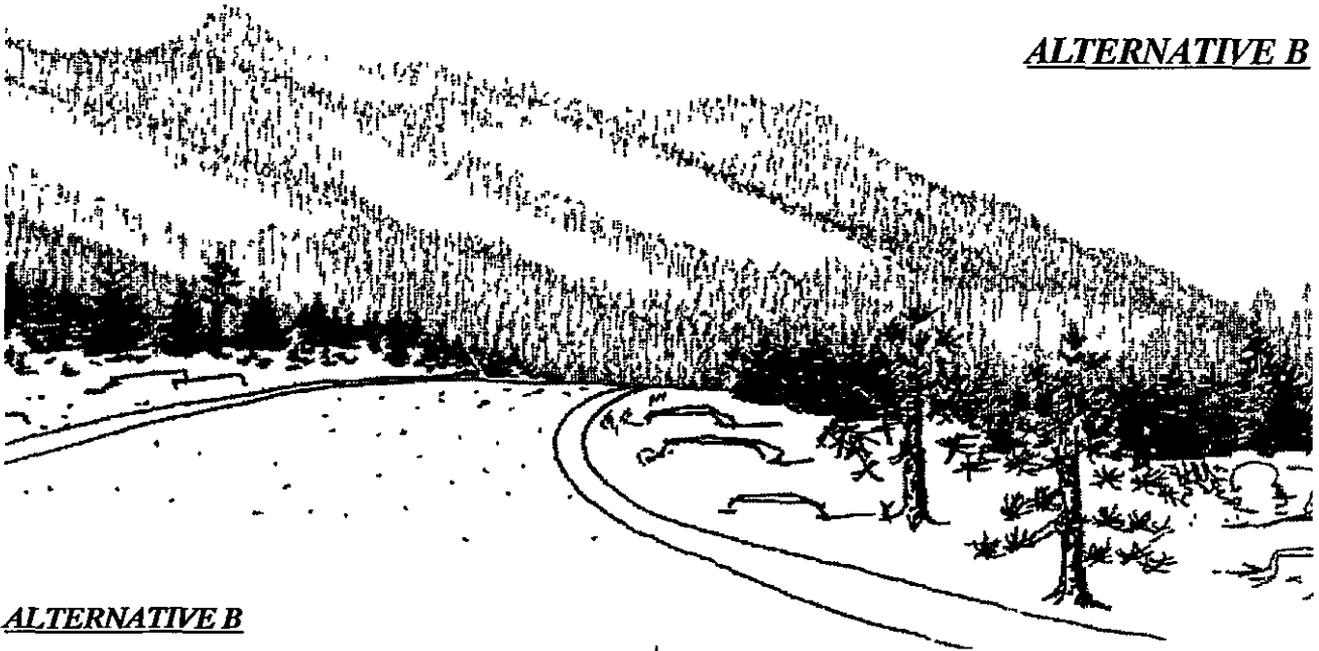

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,976 million dollars. An annual budget of 23.0 million dollars would be required for implementation. Revenues from Forest products would return 12.5 million dollars to the U.S. Treasury; 3.0 million dollars would be returned to local governments. Employment would increase by 39 jobs and income would increase by 0.65 million dollars from existing levels.

ALTERNATIVE A/NFMA
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec Visitor Days	4,883,000
Annual dispersed recreation capacity		
- Roaded	Rec Visitor Days	22,576,000
- Unroaded	Rec Visitor Days	1,009,000
- Wilderness	Rec Visitor Days	1,060,000
<u>Roadless Management</u>		
Lands allocated to roadless management other than wilderness (RE-2a & 2b, RE-3, SI-1, SI-2, RN-1, WS-3)	Acres	263,158
<u>Wild and Scenic Rivers.</u>		
- Wild	Miles	20.0
- Scenic	Miles	7.0
- Recreational	Miles	70.0
<u>Water Quality and Quantity</u>		
Water yield increase	Acre feet	13,800
Sediment increase index	Tons/year	69,200
<u>Old-Growth</u>	Acres	307,300
<u>Wildlife and Fish</u>		
Wildlife habitat management (EW-1)	Acres	17,151
Anadromous fish commercial harvest	Pounds	328,000
<u>Visual Quality Objectives</u>		
Area managed for - Preservation	Acres	842,751
- Retention	Acres	485,081
- Partial Retention	Acres	459,112
- Modification	Acres	55,629
- Maximum Modification	Acres	321,607
<u>Timber</u>		
Allowable sale quantity	Million Cubic Feet	21.8
Allowable sale quantity	Million Board Feet	121.4
Long-term sustained yield	Million Cubic Feet	27.7
Area of suitable timber land	Acres	591,794
<u>Range</u>		
Grazing capacity	Animal Unit Months	36,400
Permitted grazing	Animal Unit Months	23,000
Area of suitable grazing land	Acres	901,971
<u>Social/Economic</u>		
Present Net Value	Million Dollars	1,976
Annual cost to the Federal Government	Million Dollars	23.0
Annual revenues to the Federal Government	Million Dollars	12.5
Annual returns to Local Governments	Million Dollars	3.0
Change in employment	Number of Jobs	+39
Change in income	Million Dollars	+0.65

ALTERNATIVE B

ALTERNATIVE B

This alternative was developed in an attempt to meet the 1980 Resources Planning Act program which has been assigned to the Forest through the Regional Guide.

The 1980 RPA timber target strongly influenced our approach. This alternative uses the Alternative D land allocations. This alternative would result in the greatest amount of development of the Forest.

A feature of this alternative and Alternative D is the higher allocation to General Forest (GF) and a corresponding decrease in the unroaded and scenic travel allocations. The major difference between this alternative and Alternative D is that in Alternative B more intensive timber management will be practiced on the GF land allocation which will result in higher yields and higher annual sale quantities.

The major changes in this alternative from the DEIS and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and "dedicating" old growth spotted owl habitat areas rather than "managing."

- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.

RECREATION SETTING

--Developed Recreation

The emphasis under this alternative is to convert the more popular reduced service sites to full service status. Other popular sites will be maintained with very little improvement to existing facilities. Some expansion of existing full service sites will occur. Added coordination with the dispersed recreation component of the recreation setting would be needed because of the increased timber harvest and roading activities.

More opportunity would be available for establishing overlooks and scenic vistas in new roaded areas.

Ski areas that have current master plans and are considering expansion are Mission Ridge, White Pass, and Stevens Pass.

--Dispersed Recreation

By the second decade, 11 percent of the Forest will provide unroaded recreation opportunities outside wilderness. This includes 7,169 acres Primitive, 82,699 acres Semi-Primitive, Non-Motorized and 139,177 acres Semi-Primitive Motorized Recreation Opportunity Spectrums (ROS).

ALTERNATIVE B

In addition, there will be 50 percent of the Forest providing roaded recreation, or 1,086,321 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrums combined.

Seventeen of the 23 inventoried roadless areas will have a substantial portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	8,968	1,950
Rock Creek	32,924	17,128	15,796
Twin Lakes	22,048	13,420	8,628
Canyon Creek	9,158	4,240	4,918
Heather Lake	11,067	1,442	9,625
Chelan	71,063	41,701	29,362
Entiat	71,254	25,801	45,453
Stormy	32,500	5,406	27,094
Slide Ridge	10,091	1,060	9,031
Devil's Gulch	25,186	0	25,186
Taneum	25,122	2,438	22,684
Manastash	8,798	3,498	5,300
Norse Peak Adj.	11,300	0	11,300
Quartz	8,756	106	8,650
Naneum	6,911	0	6,911
Lion Rock	4,834	3,859	975
William O. Douglas Adj.	22,938	0	22,938
Blue Slide	18,571	2,374	16,197
Goat Rocks Adj.	7,357	0	7,357
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 4,388 acres of dedicated old growth that fall within roadless allocations.

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1,188
Unroaded Non-motorized	--	66.7
Unroaded Motorized	162.5	---
Roaded Motorized	1,045.6	---
Administratively Closed	--	390 0

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>
Tumwater	Teanaway Nason Ridge Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

There are no rivers recommended for designation under the Wild and Scenic Rivers Act. River corridors would be subject to a full range of management activities, with five of the ten eligible rivers outside wilderness being allocated to timber harvest prescriptions that could noticeably alter the scenic qualities of the landscape.

SCENERY

Visual quality objectives would remain at a high level only in the Alpine Lakes Management Unit, and the Lake Chelan and the Mather Memorial (Hwy 410) viewsheds. Slightly altered to altered scenery would be evident in the White Pass (Hwy 12) and the Entiat Valley viewsheds.

Unnatural patterns will dominate most portals to wilderness. The natural character will not be maintained.

The natural appearance of the Forest in other areas would be greatly reduced. The general impression would be of a heavily altered landscape with contrasting openings, visible logging roads, and large cut patterns.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-Wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

Approximately 80 percent of the known cultural resources would be within management area designations that may create a potentially moderate to high level of impact (59 percent would be within management areas that could be considered to have a high level of impact). These would require mitigation measures or frequent project modification. There might be substantial modification of the visual settings around several significant sites. Loss of non-significant sites might be high.

ALTERNATIVE B

A high number of acres would be inventoried for cultural resources (approximately 682,000 acres over the planning period in support of the timber program alone), but the ways in which identified sites could be managed and interpreted in place might be constrained.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information and education on wilderness ethics and minimum impact camping techniques.

Approximately 62 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains lower levels of habitat for mature and old growth species than some other alternatives.

Deer and elk populations are reduced a small amount in summer habitat and have a moderate reduction in their wintering habitat.

Primary cavity excavator habitat is reduced to the next lowest level of the alternatives.

Riparian habitat is maintained.

This alternative is on the lower end of the range of providing for recreation use of wildlife.

State wildlife objectives would be met for deer, mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 138,000 acres of suitable spotted owl habitat in lands that are unsuitable for timber management, or in allocations that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 45,305 acres originally allocated to full timber yield prescriptions, and 19,356 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the plan. By the second decade the numbers of catchable cutthroat trout are estimated to increase from a current level of 200,000 fish to 218,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1.381 million and 172,000 to 176,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is expected to remain constant at current levels through the life of the plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the fish Habitat Management Program and implementation of Best Management Practices which will maintain current habitat capability and should allow fairly natural stream processes to function, resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that approximately \$17,000 of the annual habitat improvement program will be funded through appropriated monies and \$418,000 through KV. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off the Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous fish runs in the drainage. Resident

trout habitat capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the fifth decade. Permitted use in the first decade is expected to average 23,000 AUM's, 25,500 AUM's in the second decade, and 36,000 AUM's in the fifth decade.

Demand for cattle grazing would exceed supplies by the third decade, but demand for sheep grazing will be met in all decades. Actual permitted use would not exceed the total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 48,421 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 23,808 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 98,054 acres of old growth. By the fifth decade, there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 33.5 million (MM) cubic feet (169.1 MM board feet) per year and a Timber Sale Programmed Quantity of 36.0 MMCF (181.5 MMBF) for the first five decades. The long-term sustained yield for this alternative is 34.2 MM cubic feet based on 681,186 acres of suitable timber lands. This compares to the past decade

average annual volume sold of 187.5 MMBF and an average annual volume harvested of 166.0 MMBF.

This alternative uses only GF-1 (high level of timber investment) and GF-3 in General Forest Management Areas. All acres would be managed using thinning to increase yields of sawlog size trees.

An average of 7,976 acres per year will be clearcut, 2,143 acres will be shelterwood cut, and 5,060 acres will be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. The timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 28,500, 40,200 and 39,300 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades, the activity related delivered sediment will be approximately 94,900 tons per year. By the end of the third decade, most of the roads will have been built so that the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by roughly 44 percent. Therefore, soil losses produced by management activities in the fifth decade will be approximately 53,100 tons per year.

ALTERNATIVE B

MINERALS

The area withdrawn as Wilderness (841,034 acres) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 2,247 additional acres from mineral entry which is less than 1 percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 384,868 acres or 18 percent of the total Forest areas. The following figures shows how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWAL	OPEN BUT WITH A HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	23,236 acres or 19%	36,507 acres or 31%
Area classified prospectively valuable for oil and gas	530 acres or less than 1%	29,108 acres or 14%	176,216 acres or 83%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	43,503 acres or 7 3%	132,840 acres or 23%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	126,396 acres or 24%	298,392 acres or 56%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

In this alternative it is estimated that the number of small hydroelectric proposals could increase to about 40. At least four of these could be expected to advance to the application for license stage.

ROADS

The implementation of Alternative B would require the construction of approximately 1901 miles of additional road. Some 979 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 18 years. In addition to the roads currently open, it is expected that 100% of the new roads would be opened to public use by high clearance vehicles.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

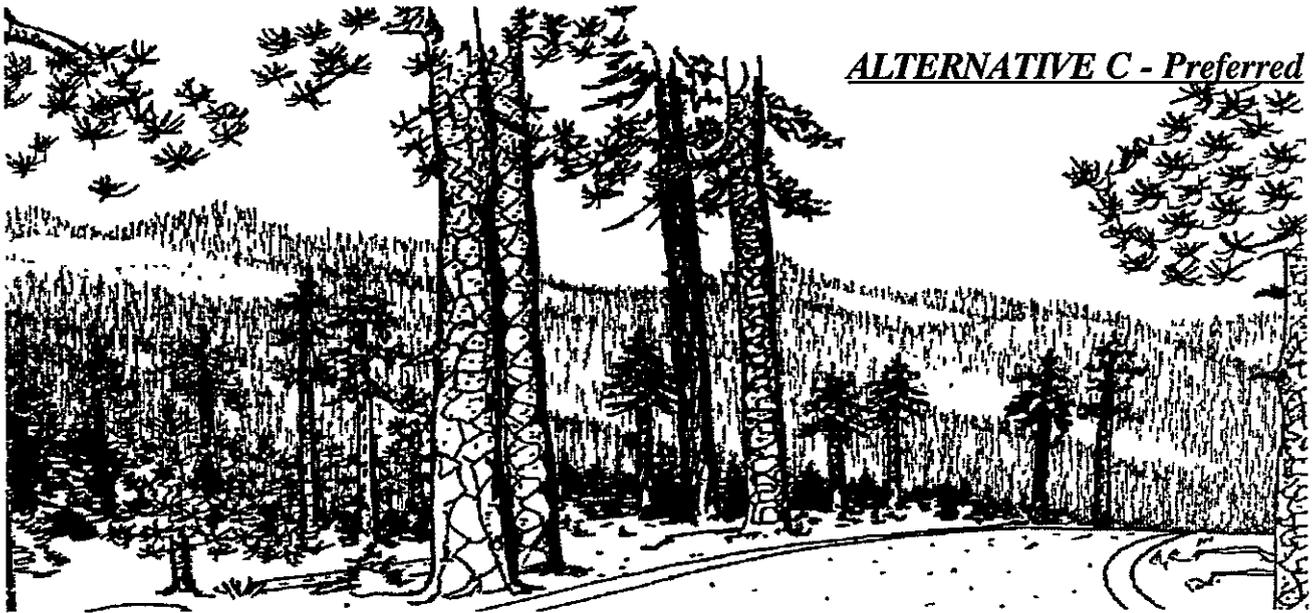

Fire hazard would decrease because of increased timber harvest and hazard reduction activities including prescribed burning. All human caused fires occurring in wilderness areas would be put out. Lightning fires in wilderness would be carefully monitored and allowed to play their natural role unless there is a threat to life, property, or important natural resources. If a threat exists, the fire will be attacked. Fire prevention efforts will be concentrated on logging-related industrial activities.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,756 million dollars. An annual budget of 34.2 million dollars would be required for implementation. Revenues from Forest products would return 8.1 million dollars to the U.S. Treasury; 2.0 million dollars would be returned to local governments. Employment would increase by 577 jobs and income would increase by 15.31 million dollars from existing levels.

ALTERNATIVE B
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec Visitor Days	6,853,000

Change in income	Million Dollars	+15 31

ALTERNATIVE C - Preferred

ALTERNATIVE C - Preferred

This alternative was developed by adjusting the current direction (Alternative A/NFMA) to a land allocation which would maximize net public benefits and would provide a balanced program in response to the issues and concerns. The purpose of Alternative C is to respond to concerns for protecting wildlife and other amenity resources, and provide a variety of recreation opportunities while managing appropriate areas of the Forest for commodity outputs. This was accomplished by modifying existing plans and practices to respond to public concerns received during issue identification early in the planning process. Further modification of this alternative has been done to respond to comments received through the public response on the Draft EIS.

Alternative C differs from Alternative A/NFMA in that it allocates many more acres to key big game range and increases the acreage allocated to roadless management.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and “dedicating” old growth spotted owl habitat areas rather than “managing.”
- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.

-Increase inventoried roadless area acreage from 267,610 acres to 298,115 acres.

-Reduction in acres allocated to unroaded motorized use.

-Development and application of the Mather Memorial Parkway prescription (MP-1) which has no scheduled timber harvest within the Parkway corridor.

-An addition of two new allocations: EW-3 (Key Big Game Habitat, Unroaded) and RE-4 (Dispersed Recreation, Unroaded, Timber Harvest).

-Changes in the classification on some of the recommended Wild and Scenic Rivers, and the addition of the Waptus River to those recommended for designation.

-An increase in acreage of Special Interest Areas.

RECREATION SETTING

--Developed Recreation

This alternative places emphasis on upgrading and expanding heavily used popular campgrounds and renovating or rehabilitating facilities in other developed recreation sites. Highly popular reduced service campgrounds in developed high use areas will be upgraded to full service sites.

ALTERNATIVE C

Campgrounds in more semi-primitive areas will remain as lesser developed sites. Facility repair in more remote semi-primitive settings will focus on sanitation, public safety and unserviceable facilities.

There will be some opportunity during timber sale activities to improve or establish overlooks and scenic vistas.

Ski areas that have current Master Plans and are considering expansion are Mission Ridge, White Pass, and Stevens Pass.

--Dispersed Recreation

By the second decade, 14% of the Forest will provide unroaded recreation opportunities

outside wilderness. This includes 7,265 acres Primitive, 115,314 acres Semi-Primitive Non-Motorized, and 175,536 acres Semi-Primitive Motorized Recreation Opportunity Spectrums (ROS).

In addition, there will be 47 percent of the Forest providing roaded recreation or 1,017,251 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrums combined.

Twenty-two of the 23 inventoried roadless areas will have all or a portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	10,918	0
Rock Creek	32,924	22,812	10,112
Twin Lakes	22,048	14,331	7,717
Canyon Creek	9,158	4,197	4,961
Heather Lake	11,067	2,714	8,353
Chelan	71,063	63,664	7,399
Entiat	71,254	35,998	35,256
Stormy	32,500	9,710	22,790
Slide Ridge	10,091	2,502	7,589
Devil's Gulch	25,186	8,586	16,600
Taneum	25,122	7,038	18,084
Manastash	8,798	6,106	2,692
Norse Peak Adj.	11,300	1,357	9,943
Quartz	8,756	1,145	7,611
Naneum	6,911	1,335	5,576
Lion Rock	4,834	3,582	1,252
William O. Douglas Adj.	22,938	191	22,747
Blue Slide	18,571	3,032	15,539
Goat Rocks Adj.	7,357	1,293	6,064
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 6,232 acres of dedicated old growth that fall within roadless allocations

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1188.0
Unroaded Non-motorized	--	139.7
Unroaded Motorized	190.4	---
Roaded Motorized	944.7	---
Administratively Closed	--	379.4

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

Scenic	Dispersed Recreation	Old Growth
Turnwater	Teanaway Nason Ridge Annette Lake	Hornet Ridge Rattlesnake Springs Heather Lake Trailhead Fish Creek (Lake Wenatchee) The Sanctuary
Ecological	Botanical	Geological
Squaw Lake area Fish Lake Run Twin Lake Ponds Upper Naneum Meadow	Turnwater Ponderosa Estates Goose Egg Blue Slide	Boulder Cave Kloochman Rock Goose Egg Blue Slide

WILD, SCENIC, AND RECREATIONAL RIVERS

The American, Cle Elum, Waptus, Icicle, Napeequa, White, Chiwawa, Wenatchee, and Entiat Rivers have all been given a preliminary administrative recommendation for Wild and Scenic River designation. The proposed classifications are shown in the table below. The only eligible river not recommended for inclusion in the National System is the Little Wenatchee. However, the corridor here will be managed for a visual quality objective of retention, and fisheries habitat will be protected through special riparian prescriptions. For a more complete discussion of this topic, refer to Appendix E of the FEIS.

River	Recommended Classification	Miles	Segment
American	Wild	6.0	Headwaters to confluence with Rainier Fork.
	Scenic	16.0	Confluence with Rainier Fork to confluence with Bumping River (in Mather Memorial Parkway corridor).
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary
	Recreational	24.0	Glacier Peak Wilderness boundary to Goose Creek.
	Recreational	6.0	Goose Creek to confluence with Wenatchee River.
Cle Elum	Wild	4.0	Headwaters to Alpine Lakes Wilderness boundary.
	Scenic	2.0	Alpine Lakes Wilderness boundary to above Lake Tucquala.
	Recreational	14.0	Above Lake Tucquala to Salmon La Sac bridge.
	Recreational	4.5	Salmon La Sac bridge to Lake Cle Elum
Entiat	Wild	12.5	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	4.0	Glacier Peak Wilderness boundary to Cottonwood Trailhead
	Recreational	15.0	Cottonwood Trailhead to above Burns Creek.
Icicle	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary
	Recreational	14.0	Alpine Lakes Wilderness boundary to above Leavenworth city water intake.
Napeequa	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Recreational	1.0	Glacier Peak Wilderness boundary to confluence with White River.
Waptus	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary.
	Wild	1.0	Alpine Lakes Wilderness boundary to confluence with Cle Elum River.
Wenatchee	Recreational	21.0	Lake Wenatchee to Tumwater Campground.
	Recreational	7.0	Tumwater Campground to Forest boundary.
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch.
	Recreational	12.0	Above Tall Timbers Ranch to Lake Wenatchee.

The characteristics that contribute to the eligibility of these rivers will be protected until Congress formally determines their status.

SCENERY

Visual quality is maintained at a high level for all major interstate scenic highway viewsheds, the Alpine Lakes Management Unit, and most major wilderness portals.

Unnatural landscape patterns would occur in a few major viewsheds such as Cooper Mountain to South Navarre, Little Naches, Cash Prairie, Little Rattlesnake, North and South Fork Tieton.

The natural appearance of the remainder of the Forest as viewed from Forest roads would be altered.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

Old growth preservation for aesthetic reasons are in Old Growth (OG-1) and Special Interest (SI-2) management prescriptions.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

A majority of the known cultural resources (77 percent) would be within management area designations that may create a potentially moderate to high level of impact. These would require mitigation. Visual settings around some significant sites might experience modification apparent to the viewer. Opportunities would be good to enhance several significant historic sites through treatment of the adjacent vegetation in conjunction with the Forest timber management program.

There would be a moderate number of acres inventoried for cultural resources (approximately 577,000 acres over the planning period). Accessibility to cultural sites managed for interpretation would be very good.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious use of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information and education on wilderness ethics and minimum impact camping techniques.

Approximately 58 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains moderate levels of habitat for mature and old growth species compared to other alternatives.

Deer and elk populations will decrease a small amount in summer habitat and will increase in their winter habitat.

Primary cavity excavator habitat is maintained near the middle of the range of the alternatives.

Riparian habitat is maintained.

This alternative is in the middle of the range of alternatives in providing for recreation use of wildlife.

State wildlife objectives would be met for deer, mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 165,000 acres of suitable spotted owl habitat in lands that are unsuitable for timber management or in alloca-

tions that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 29,511 acres originally allocated to full timber yield prescriptions and 37,991 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the Plan. Numbers of catchable trout by the second decade are estimated to increase from a current level of 200,000 fish to 212,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1 395 million and 172,000 to 178,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is expected to remain constant at current levels through the life of the Plan.

It is anticipated that increase in habitat capability will result from Riparian Habitat Management Standards and the Fish Habitat Management Program. Beyond this, implementation of Best Management Practices will maintain current habitat capability and should allow fairly natural stream processes to function, resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that approximately \$189,000 of the annual habitat improvement program will be funded through appropriated monies and \$246,000 through Knutson-Vandenburg (KV) monies. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage around dams off the Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous fish runs in the drainage. Resident trout habitat capability will also improve providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase slightly above the current level through the fifth decade. Permitted use in the first decade is expected to average 23,000 AUM's, 24,000 AUM's in the second decade, and 24,000 AUM's in the fifth decade. Demand for cattle grazing would exceed available supply by the third decade, but demand for sheep grazing would be met in all decades. Actual permitted use would not exceed the total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 64,343 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 20,161 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 85,779 acres of old growth. By the fifth decade, there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 24.3 million (MM) cubic feet (136 MM board feet) per year and a Timber Sale Programmed Quantity of 26.1 MMCF (146.0 MMBF) for the first five decades. The long-term sustained yield for this alternative is 27.2 MM cubic feet based on 576,074 acres of suitable timber lands. This compares to the past decade average annual volume sold of 187.5 MMBF and an average annual volume harvested of 166.0 MMBF.

A wide range of timber intensities were selected ranging from GF-1 (high level of timber investment) to GF-6 in General Forest Management Areas. Approximately 50% of the general forest acres will receive intensive management including tree spacing (thinning). The other 50% will not be thinned due to economics, growth potential after thinning, or other physical and biological reasons.

An average of 3,433 acres per year will be clearcut, 2,360 acres will be shelterwood cut, and 2,896 acres will be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) Standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 15,500, 21,000 and 23,800 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades the activity related delivered sediment will be approximately 72,400 tons per year. By the end of the third decade, most of the roads will have been built so the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by roughly 44 percent; therefore, soil losses produced by management activities in the fifth decade will be approximately 40,500 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 2,247 additional acres from mineral entry, which is less than 1 percent of the total Forest acres. In addition to the withdrawals, management prescriptions which could discourage mineral related activities, would be used to manage 482,876 acres or 22 percent of the total Forest acres.

The following table shows how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWAL	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	28,599 acres or 24%	31,143 acres or 26%
Area classified prospectively valuable for oil and gas	530 acres or less than 1%	44,330 acres or 21%	160,994 acres or 76%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	58,767 acres or 9.8%	117,576 acres or 20%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	155,758 acres or 29%	269,030 acres or 50%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

In this alternative it is estimated that the number of small hydroelectric proposals would be about 25. Three or four of these could be expected to reach the application for license stage.

ROADS

The implementation of Alternative C would require the construction of approximately 1,486 miles of additional road. Some 706 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 18 years. It is expected that none of the new roads would be opened to public use by high clearance vehicles. Roads that are currently open would be expected to remain open.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. An unplanned natural fire occurring in wilderness would be treated as a prescribed fire until declared a wildfire. Human-caused fires occurring in wilderness would require an appropriate suppression response. Prescribed fire would be used for the reduction of activity fuels (logging and road building slash) and for maintenance and improvement of other resources as a management tool.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,910 million dollars. An annual budget of 29.0 million dollars would be required for implementation. Revenues from Forest products would return 14.0 million dollars to the U.S. Treasury; 3.3 million dollars would be returned to local governments. Employment would increase by 203 jobs and income would increase by 5.14 million dollars from existing levels.

ALTERNATIVE C**SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)**

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec Visitor Days	6,683,000
Annual dispersed recreation capacity		
- Roaded	Rec Visitor Days	21,884,000
- Unroaded		984,000
- Wilderness		1,060,000
<u>Roadless Management</u>		
Lands allocated to roadless management other than wilderness (RE-2a & 2b, RE-3, SI-1, SI-2, RN-1, EW-3, RE-4)	Acres	313,677
<u>Wild and Scenic Rivers</u>		
- Wild	Miles	82.5
- Scenic	Miles	29.0
- Recreational	Miles	118.5
<u>Water Quality and Quantity</u>		
Water yield increase	Acre Feet	15,500
Sediment increase index	Tons/Year	72,400
<u>Old-growth</u>	Acres	307,300
<u>Wildlife and Fish</u>		
Wildlife habitat management (EW-1 & EW-3)	Acres	137,801
Anadromous fish commercial harvest	Pounds	328,000
<u>Visual Quality Objectives</u>		
Area managed for - Preservation	Acres	843,281
- Retention	Acres	521,800
- Partial Retention	Acres	332,927
- Modification	Acres	147,828
- Maximum Modification	Acres	318,344
<u>Timber</u>		
Allowable sale quantity	Million Cubic Feet	24.3
Allowable sale quantity	Million Board Feet	136.0
Long-term sustained yield	Million Cubic Feet	27.2
Area of suitable timber land	Acres	576,074
<u>Range</u>		
Grazing capacity	Animal Unit Months	38,700
Permitted grazing	Animal Unit Months	23,000
Area of suitable grazing land	Acres	898,184
<u>Social/Economic</u>		
Present Net Value	Million Dollars	1,910
Annual cost to the Federal Government	Million Dollars	29.0
Annual revenues to the Federal Government	Million Dollars	14.0
Annual returns to Local Governments	Million Dollars	3.3
Change in employment	Number of Jobs	+203
Change in income	Million Dollars	+5.14

ALTERNATIVE D

This alternative emphasizes the production of resources such as timber, range forage, developed recreation, minerals, and other resources which have the potential to return revenue to the Federal Treasury and local Counties. Management of other resources is at economically and environmentally feasible levels consistent with the emphasis on market oriented outputs.

A feature of this alternative and Alternative B is the higher allocation to General Forest (GF) and a corresponding decrease in the unroaded and scenic travel allocations. The major difference between this alternative and Alternative B is the economic emphasis. This results in less intensive timber management on the GF land allocation, and a lower annual sale quantity with an increased present net value compared to Alternative B.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.

- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.

RECREATION SETTING

--Developed Recreation

The emphasis of this alternative is to upgrade and expand heavily used popular campsites and develop new sites where capacity is being fully utilized. Highly popular reduced service campgrounds in high use areas will be upgraded to full service sites. Campgrounds in remote semi-primitive areas will remain as lesser developed sites. All deteriorating facilities at campgrounds will be renovated.

Increased timber roading would provide more opportunity for commercial resorts in choice locations. These opportunities would be captured by entrepreneurs as the demand for such facilities develops.

Ski areas would be encouraged to look at their master plans for inclusion of more area for expansion. These are the Mission Ridge, White Pass, Stevens Pass, and Crystal Mountain areas.

--Dispersed Recreation

By the second decade, 11% of the Forest will provide unroaded recreation opportunities. This includes 9,464 acres Primitive, 80,404 acres Semi-Primitive Non-Motorized, and 139,177 acres Semi-Primitive Motorized Recreation Opportunity Spectrums (ROS).

In addition, there will be 50 percent of the Forest providing roaded recreation or 1,086,321 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrums combined.

Seventeen of the 23 inventoried roadless areas will have a substantial portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	8,968	1,950
Rock Creek	32,924	17,128	15,796
Twin Lakes	22,048	13,420	8,628
Canyon Creek	9,158	4,240	4,918
Heather Lake	11,067	1,442	9,625
Chelan	71,063	41,701	29,362
Entiat	71,254	25,801	45,453
Stormy	32,500	5,406	27,094
Slide Ridge	10,091	1,060	9,031
Devil's Gulch	25,186	0	25,186
Taneum	25,122	2,438	22,684
Manastash	8,798	3,498	5,300
Norse Peak Adj.	11,300	0	11,300
Quartz	8,756	106	8,650
Naneum	6,911	0	6,911
Lion Rock	4,834	3,859	975
William O. Douglas Adj.	22,938	0	22,938
Blue Slide	18,571	2,374	16,197
Goat Rocks Adj.	7,357	0	7,357
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 4,388 acres of dedicated old growth that fall within roadless allocations.

ALTERNATIVE D

The miles of trail available to motorized use by land allocation or due to administrative closures are:

<u>Allocation</u>	<u>Miles Open to Motorized Use</u>	<u>Miles Closed to Motorized Use</u>
Wilderness	--	1188.0
Unroaded Non-motorized	--	66.7
Unroaded Motorized	162.5	---
Roaded Motorized	1045.6	---
Administratively Closed	--	390.0

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

Scenic

Dispersed Recreation

Tumwater

Teanaway
Nason Ridge
Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

There are no rivers recommended for designation under the Wild and Scenic Rivers Act. River corridors would be subject to a full range of management activities, with five of the ten eligible rivers outside wilderness being allocated to timber harvest prescriptions that could noticeably alter the scenic qualities of the landscape.

SCENERY

Visual quality objectives would remain at a high level only in the Alpine Lakes Management Unit and the Lake Chelan and Mather Memorial (Hwy-410) viewsheds. Visual quality on the White Pass (Hwy 12) and the Entiat Valley viewsheds would be slightly altered to altered.

Unnatural patterns will dominate most portals to wildernesses. The natural character will not be maintained.

The natural appearance of the Forest in other areas would be greatly reduced. The general viewing impression would be one of a heavily altered landscape with contrasting openings, visible logging roads, and large cut patterns.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

Approximately 80 percent of the known cultural resources would be within management area designations that may create a potentially moderate to high level of impact (59 percent would be within management areas that could be considered to have a high level of impact). These would require mitigation measures or frequent project modification. There might be noticeable modification of the visual settings around several significant sites. There might be an increase in the loss of non-significant sites.

A high number of acres would be inventoried for cultural resources (approximately 644,000 acres over the planning period in support of the timber program alone), but the ways in which identified sites could be managed and interpreted in place might be constrained.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 62 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains lower levels of habitat for mature and old growth species compared to other alternatives.

Deer and elk populations are reduced a small amount in summer habitat and have a moderate reduction in winter habitat.

Primary cavity excavator habitat is reduced to the second lowest level of the alternatives.

Riparian habitat is maintained.

This alternative is on the lower end of the range of providing for recreation use of wildlife.

State wildlife objectives would be met for deer, mountain goats, grouse and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 138,000 acres of suitable spotted owl habitat in lands that are unsuitable for timber management or in allocation that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 45,305 acres originally allocated to full timber yield prescriptions and 19,356 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the plan. Numbers of catchable trout by the second decade are estimated to increase from a current level of 200,000 to 212,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1.368 million and 172,000 to 174,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is expected to remain constant at current levels through the life of the plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices, which will maintain current habitat capability and should allow fairly natural stream processes to function, resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that, under this alternative, the \$295,000 annual habitat improvement program will be funded through Knutson-Vandenburg monies. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous fish runs in the drainage. Resident trout habitat

ALTERNATIVE D

capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the fifth decade. Permitted use in the first decade is expected to average 23,000 AUM's, 25,500/AUM's in the second decade, and 36,000 AUM's in the fifth decade. Demand for cattle grazing would exceed supplies by the third decade, but demand for sheep grazing would be met in all decades. Actual permitted use would not exceed the total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 48,421 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 23,808 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 98,054 acres of old growth. By the fifth decade, there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 25.6 million (MM) cubic feet (142.7 MM board feet) and a Timber Sale Programmed Quantity of 27.4 MMCF (153.2 MMBF) per year for the first five decades. The long-term sustained yield for this alternative is 30.8 MM cubic feet based on 643,639 acres of suitable timber lands. This compares to the past decade average annual volume sold of 187.5 MMBF and average annual volume harvested of 166.0 MMBF.

A wide range of timber intensities were selected ranging from GF-1 (high level of timber investment) to GF-6 in General Forest Management Areas. Approximately 31% of the general forest acres will receive intensive management including tree spacing (thinning). The other 69% will not be thinned.

An average of 5,136 acres per year will be clearcut, 24 acres will be shelterwood cut, and 2,569 acres will be selective cut.

WATER

Water quality and yield parameters are affected by degree of commodity production. Refer to Chapter IV for a discussion of the variation in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 15,700, 22,200 and 24,900 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades, the activity related delivered sediment will be approximately 65,500 tons per year. By the end of the third decade, most of the roads will have been built, so the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by roughly 44 percent; therefore, soil losses produced by management activities in the fifth decade will be approximately 36,700 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 2,247 additional acres from mineral entry, which is less than 1 percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 384,868 acres or 18 percent of the total Forest acres. The following figure shows how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWAL	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 Acres or less than 1%	23,236 acres or 19.5%	36,507 acres or 30.5%
Area classified prospectively valuable for oil and gas	530 acres or less than 1%	29,108 acres or 14%	176,216 acres or 83%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	43,503 acres or 7%	132,840 acres or 22%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	126,396 acres or 24%	298,392 acres or 56%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

In this alternative, it is estimated that the number of small hydroelectric proposals would be 40 or more. At least four of these could be expected to advance to the application for license state.

ROADS

The implementation of Alternative D would require the construction of approximately 1,630 miles of additional road. Some 853 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 20 years. It is expected that none of the new roads would be opened to public use by high clearance vehicles. Roads that are currently open would be expected to remain open.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. Lightning fires occurring in wilderness would be treated as prescribed fire until declared a wildfire. Human caused fires occurring in wilderness would require an appropriate suppression response. The fire hazard would decrease because increased timber harvest and fuel reduction activities would reduce forest fuels. Fire prevention efforts would be directed toward timber harvest activities.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,937 million dollars. An annual budget of 26.9 million dollars would be required for implementation. Revenues from Forest products would return 14.3 million dollars to the U.S. Treasury; 3.4 million dollars would be returned to local governments. Employment would increase 279 jobs, and income would increase by 7.2 million dollars from existing levels.

ALTERNATIVE D
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec Visitor Days	6,853,000
Annual dispersed recreation capacity		
- Roaded	Rec Visitor Days	22,410,000
- Unroaded		950,000

Area of suitable timber land	Acres	643,639
<u>Range</u>		
Grazing capacity	Animal Unit Months	39,700
Permitted grazing	Animal Unit Months	23,000
Area of suitable grazing land	Acres	902,753
<u>Social/Economic</u>		
Present Net Value	Million Dollars	1,937
Annual cost to the Federal Government	Million Dollars	26.9
Annual revenues to the Federal Government	Million Dollars	14.3
Annual returns to Local Governments	Million Dollars	3.4
Change in employment	Number of Jobs	+279
Change in income	Million Dollars	+7.2

ALTERNATIVE E

This alternative allocates all inventoried currently roadless areas outside of the existing wilderness and the Alpine Lakes Management Area to a management prescription which will maintain their roadless status. It also emphasizes the protection of natural scenery, fish and wildlife habitat, and other amenity values. Management of other resources would be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.
- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.
- Development and application of the Mather Memorial Parkway prescription (MP-1) which has no scheduled timber harvest within the Parkway corridor.

RECREATION SETTING

--Developed Recreation

The emphasis for this alternative is to bring selected sites up to full service status and convert these sites to full service campgrounds. Some minor expansion of these sites as well as the present full service sites will take place in popular areas.

As the roadless areas will not be accessed for timber harvest, the opportunities for additional areas for developed site activities will be limited to the existing roaded drainages.

The Mission Ridge, White Pass, and Stevens Pass ski areas have master plans and development of these areas would continue on an orderly basis depending on public demand and economic conditions.

--Dispersed Recreation

By the second decade, 23% of the Forest will provide unroaded recreation opportunities outside wilderness. This includes 3,114 acres Primitive, 342,639 acres Semi-Primitive Non-Motorized, and 153,572 acres Semi-Primitive Motorized Recreation Opportunity Spectrums (ROS).

In addition, there will be 41 percent of the Forest providing roaded recreation or 886,041 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrums combined.

All of the 23 inventoried roadless areas will have all or a portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS	ACRES TO BE ROADDED
Myrtle Lake	10,918	10,918	0
Rock Creek	32,924	32,924	0
Twin Lakes	22,048	22,048	0
Canyon Creek	9,158	9,158	0
Heather Lake	11,067	11,067	0
Chelan	71,063	71,063	0
Entiat	71,254	71,254	0
Stormy	32,500	30,868	1,632 ^{1/}
Slide Ridge	10,091	10,091	0
Devil's Gulch	25,186	25,186	0
Taneum	25,122	25,122	0
Manastash	8,798	8,798	0
Norse Peak Adj.	11,300	11,300	0
Quartz	8,756	8,756	0
Naneum	6,911	6,911	0
Lion Rock	4,834	4,834	0
William O. Douglas Adj.	22,938	22,938	0
Blue Slide	18,571	18,571	0
Goat Rocks Adj	7,357	7,357	0
Nason Ridge	19,123	12,063	7,060 ^{2/}
Alpine Lakes Adj.	44,393	28,513	15,880 ^{2/}
Thorp Mountain	15,667	4,388	11,279 ^{2/}
Teanaway	66,293	52,640	13,653 ^{2/}

^{1/} Experimental Forest area within the boundaries of this inventoried roadless area

^{2/} Located within the Alpine Lakes Management Area

Four of the 23 inventoried roadless areas lie within the Alpine Lakes Management Area. Management of these areas is directed by the Alpine Lakes Area Land Management Plan and Environmental Impact Statement (1981) that was mandated through the Alpine Lakes Management Act (36 CFR, Part 219.2 {b}). Within these four areas, the Alpine Lakes Management Plan is the guiding document when there is a conflict in management direction between it and the proposed Forest Plan. Therefore, these four areas will have some areas roaded.

ALTERNATIVE E

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1188.0
Unroaded Non-motorized	--	112.7
Unroaded Motorized	463.6	--
Roaded Motorized	697.8	--
Administratively Closed	--	621.2

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>
Tumwater	Teanaway Nason Ridge Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

The American, Cle Elum, Waptus, Entiat, Icicle, Little Wenatchee, White, Napeequa, Chiwawa and Wenatchee Rivers are recommended for designation under the Wild and Scenic Rivers Act. The classification by segment is described in the following table:

River	Recommended Classification	Miles	Segment
American	Wild	6.0	Headwaters to confluence with Rainier Fork.
	Scenic	16.0	Confluence with Rainier Fork to confluence with Bumping River (in Mather Memorial Parkway corridor).
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary
	Scenic	24.0	Glacier Peak Wilderness boundary to Goose Creek
	Recreational	6.0	Goose Creek to confluence with Wenatchee River.
Cle Elum	Wild	4.0	Headwaters to Alpine Lakes Wilderness boundary.
	Scenic	2.0	Alpine Lakes Wilderness boundary to above Lake Tucquala
	Scenic	14.0	Above Lake Tucquala to Salmon La Sac bridge
	Recreational	4.5	Salmon La Sac bridge to Lake Cle Elum
Entiat	Wild	12.5	Headwaters to Glacier Peak Wilderness boundary
	Wild	4.0	Glacier Peak Wilderness boundary to Cottonwood Trailhead.
	Scenic	15.0	Cottonwood Trailhead to above Burns Creek
Iceicle	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary.
	Scenic	14.0	Alpine Lakes Wilderness boundary to above Leavenworth city water intake.
Little Wenatchee	Scenic	8.0	Little Wenatchee Falls to Lake Wenatchee
Napeequa	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary
	Recreational	1.0	Glacier Peak Wilderness boundary to confluence with White River.
Waptus	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary
	Wild	1.0	Alpine Lakes Wilderness boundary to confluence with Cle Elum River
Wenatchee	Recreational	21.0	Lake Wenatchee to Tumwater Campground.
	Recreational	7.0	Tumwater Campground to Forest boundary.
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch.
	Recreational	12.0	Above Tall Timbers Ranch to Lake Wenatchee.

Characteristics which contribute to the eligibility of these rivers will be protected until Congress formally determines their status

ALTERNATIVE E

SCENERY

Visual quality would be maintained at the highest level. All major interstate scenic highway viewsheds would retain a natural appearing landscape.

All identified viewsheds in wilderness portals and the Alpine Lakes Management Unit would retain a natural appearance.

Chumstick - Plain, Sugarloaf-Maverick Saddle, Mission Creek, Rattlesnake Creek, and Table Mountain-Reecer Creek viewsheds would retain high visual quality.

The majority of the landscape would be characterized by a natural appearance. The balance of the landscape viewed from Forest roads would have an altered appearance.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCES

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

A majority of the cultural resources would be within management area designations having potential for a low to moderate level of impact. Protection (through avoidance) of non-significant sites would be likely. The necessity of mitigation measures or project modifications would be infrequent, with greater latitude for preservation and protection of cultural resources in place. Visual settings around significant sites would likely be unaltered. However, there might also be fewer opportunities to economically manage the vegetation adjacent to such sites. The accessibility of some sites managed for interpretive purposes would be limited to non-motorized means only.

A somewhat smaller number of acres would be inventoried for cultural resources (approximately 411,000 acres over the planning period would be surveyed in support of the Forest timber program).

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 36 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains the highest levels of habitat for mature and old growth species compared to other alternatives.

Deer and elk populations are increased in both summer and winter habitat.

This alternative is the only one that increases primary cavity excavator habitat.

Riparian habitat is increased.

This alternative provides the highest level of recreation use of wildlife.

State wildlife objectives will be met for elk, deer, mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and

Research Natural Areas, and 235,000 acres of suitable spotted owl habitat in lands that are unsuitable for timber management or in allocations that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 8,756 acres originally allocated to full timber yield prescriptions and 46,344 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in a increase in both anadromous and resident fish habitat capability through the life of the plan. Numbers of catchable trout, by the second decade, are estimated to increase from a current level of 200,000 to 217,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.3 to 1.5 million and 172,000 to 185,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is estimated to remain constant at current levels through the life of the Plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices, which will maintain current habitat capability and should allow fairly natural stream processes to function, resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that approximately \$680,000 of the annual habitat improvement program will be funded through appropriated monies and \$167,000 through Knutson-Vandenburg funds. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous fish runs in the drainage. Resident trout habitat capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the third decade and would only have a slight increase in the fourth through fifth decades. Permitted use in the first decade is expected to average 23,000 AUM's, 25,500 AUM's in the second decade, and 31,500 AUM's in the fifth decade. Demand for cattle grazing would exceed supply by the middle of the second decade but demand for sheep grazing could be met in all decades. Actual permitted use would not exceed total potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 105,556 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 15,095 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 57,562 acres of old growth. By the fifth decade there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 12.9 million (MM) cubic feet (71.9 MM board feet) and a Timber Sale Programmed Quantity of 13.8 MMCF (75.7 MMBF) per year for the first five decades. The long-term sustained yield for this alternative is 18.7 MM cubic feet based on 410,935 acres of suitable timber lands. This compares to the past decade average annual volume sold of 187.5 MMBF and average volume harvested of 166.0 MMBF.

ALTERNATIVE E

This alternative would manage general forest land at a low to moderate intensity. No acres are programmed for the most intensive management that includes both precommercial and commercial thinning.

An average of 611 acres per year will be clearcut, 2,600 acres will be shelterwood cut, and 1,605 acres will be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in the alternative would result in annual water yield increases for the first, second and fifth decades of 8,200, 11,500 and 14,700 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades, the activity related delivered sediment will be approximately 50,300 tons per year. By the end of the third decade, most of the roads will be in place, and the Forest should have a good transportation network in place. Because of that, it is anticipated that the amount of delivered sediment will be reduced by roughly 44 percent; therefore, the amount of soil loss produced in the fifth decade should be approximately 28,200 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres or 39 percent of the Forest) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 3,837 additional acres from mineral entry, which is less than 1 percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions, which could discourage mineral related activities, would be used to manage 654,598 acres or 30 percent of the total Forest acres. The following figure shows how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWAL	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	36,379 acres or 30%	23,363 acres or 19.6%
Area classified prospectively valuable for oil and gas	530 acres or less than 1%	63,792 acres or 30%	141,532 acres or 67%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	95,189 acres or 16%	81,154 acres or 14%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	199,091 acres or 37%	225,697 acres or 42%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

Land use designations in this alternative would appear to limit small hydroelectric projects to about 10 proposals. Perhaps one or two would proceed to the application for license stage. However, the current level of activity must be considered. Even in this alternative, about 25 proposals would be the minimum with 3 of them reaching the application for license stage.

ROADS

The implementation of Alternative E would require the construction of approximately 830 miles of additional road. Some 180 miles of this construction is expected to take place in areas that are currently unroaded within the Alpine Lakes Management Unit. It is assumed that the majority of this construction will occur in the next 20 years. It is expected that none of the new roads would be opened to public use by high clearance vehicles. Roads currently open, would be expected to remain open.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. Unplanned natural ignitions occurring in wilderness areas would be treated as prescribed fire until declared a wildfire. Human caused fires occurring in wilderness areas would require an appropriate suppression response. Fire protection would be concentrated on high production market output areas. Prescribed burning from unplanned ignitions would be used extensively to create diversified forest conditions.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,834 million dollars. An annual budget of 24.8 million dollars would be required for implementation. Revenues from Forest products would return 8.0 million dollars to the U.S. Treasury; 1.9 million dollars would be returned to local governments. Employment would decrease by 520 jobs and income would decrease by 14.56 million dollars from existing levels.

ALTERNATIVE E
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec Visitor Days	5,033,000

Annual returns to Local Governments	Million Dollars	1 9
Change in employment	Number of Jobs	-520
Change in income	Million Dollars	-14 56

ALTERNATIVE F

ALTERNATIVE F

This alternative emphasizes unroaded recreation, protection of natural scenery, fish and wildlife habitat and other amenity values. It allocates approximately 80 percent of the currently roadless area outside of the existing wilderness and Alpine Lakes Management Area to roadless management prescriptions with heavy emphasis to non-motorized recreation. Management of other resources would be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

The Forest was assisted in the development of this alternative by a coalition of environmental groups from throughout the state.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.
- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.
- Development and application of the Mather Memorial Parkway prescription (MP-1) which has no scheduled timber harvest within the Parkway corridor.

RECREATION SETTING

--Developed Recreation

The emphasis for this alternative is to bring selected sites up to full service status. Some minor expansion of these sites as well as the present full service sites will take place in popular areas.

As the roadless areas will not be accessed for timber harvest, the opportunities for additional areas for developed site activities will be limited to the existing roaded drainages.

The Mission Ridge, White Pass, and Stevens Pass Ski Areas have master plans and development of these areas would continue on an orderly basis depending on public demand and economic conditions.

--Dispersed Recreation

By the second decade, 20% of the Forest will provide unroaded recreation opportunities which include 3,606 acres primitive, 280,180 acres semi-primitive non-motorized, and 150,572 acres semi-primitive motorized Recreation Opportunity Spectrums (ROS).

ALTERNATIVE F

In addition, there will be 41 percent of the Forest providing roaded recreation or 881,357 acres of the roaded natural and roaded modified Recreation Opportunity Spectrums combined.

All of the 23 inventoried roadless areas will have all or a portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	10,897	21
Rock Creek	32,924	31,652	1,272
Twin Lakes	22,048	21,306	742
Canyon Creek	9,158	8,904	254
Heather Lake	11,067	8,989	2,078
Chelan	71,063	60,548	10,515
Entiat	71,254	64,873	6,381
Stormy	32,500	29,087	3,413
Slide Ridge	10,091	9,243	848
Devil's Gulch	25,186	21,794	3,392
Taneum	25,122	23,808	1,314
Manastash	8,798	6,063	2,735
Norse Peak Adj.	11,300	1,336	9,964
Quartz	8,756	6,254	2,502
Naneum	6,911	5,957	954
Lion Rock	4,834	4,558	276
William O. Douglas Adj.	22,938	2,586	20,352
Blue Slide	18,571	14,861	3,710
Goat Rocks Adj.	7,357	3,689	3,668
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 4,388 acres of dedicated old growth that fall within roadless allocation.

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1,188.0
Unroaded Non-motorized	--	337.4
Unroaded Motorized	197.0	---
Roaded Motorized	740.4	---
Administratively Closed	--	364.6

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>
Tumwater	Teanaway Nason Ridge Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

The American, Cle Elum, Wapatus, Entiat, Icicle, Little Wenatchee, White, Napeequa, Chiwawa and Wenatchee Rivers are recommended for designation under the Wild and Scenic Rivers Act. The classification by segment is described in the following table:

River	Recommended Classification	Miles	Segment
American	Wild	6.0	Headwaters to confluence with Rainier Fork
	Scenic	16.0	Confluence with Rainier Fork to confluence with Bumping River (in Mather Memorial Parkway corridor).
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary
	Scenic	24.0	Glacier Peak Wilderness boundary to Goose Creek.
	Recreational	6.0	Goose Creek to confluence with Wenatchee River.
Cle Elum	Wild	4.0	Headwaters to Alpine Lakes Wilderness boundary
	Scenic	2.0	Alpine Lakes Wilderness boundary to above Lake Tucquala.
	Scenic	14.0	Above Lake Tucquala to Salmon La Sac bridge
	Recreational	4.5	Salmon La Sac bridge to Lake Cle Elum
Entiat	Wild	12.5	Headwaters to Glacier Peak Wilderness boundary.
	Wild	4.0	Glacier Peak Wilderness boundary to Cottonwood Trailhead
	Scenic	15.0	Cottonwood Trailhead to above Burns Creek
Iceicle	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary
	Scenic	14.0	Alpine Lakes Wilderness boundary to above Leavenworth city water intake.
Little Wenatchee	Scenic	8.0	Little Wenatchee Falls to Lake Wenatchee
Napeequa	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Recreational	1.0	Glacier Peak Wilderness boundary to confluence with White River.
Wapatus	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary
	Wild	1.0	Alpine Lakes Wilderness boundary to confluence with Cle Elum River.
Wenatchee	Recreational	21.0	Lake Wenatchee to Tumwater Campground
	Recreational	7.0	Tumwater Campground to Forest boundary
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch.
	Recreational	12.0	Above Tall Timbers Ranch to Lake Wenatchee.

Characteristics which contribute to the eligibility of these rivers will be protected until Congress formally determines their status.

SCENERY

Visual quality would be maintained at a high level. All major interstate scenic highway viewsheds would retain a natural or slightly altered appearance.

Visual quality in the Alpine Lakes Management Unit would be high and all identified viewsheds and wilderness portals would retain their natural appearance.

Mad River, Sugarloaf to Maverick Saddle, Chumstick-Plain, Mission Creek, Table Mountain-Reecer Creek, Taneum/Manastash Quartz Mountain, Bumping Lake, and Rattlesnake Creek viewsheds would all retain high visual quality.

The general impression of the majority of the landscape would focus on its natural appearance. The remaining landscape viewed from Forest roads would have an altered appearance.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

A majority of the cultural resources would be within management area designations having potential for a low to moderate level of impact. Protection (through avoidance) of non-significant sites would be likely. The necessity of mitigation measures or project modifications would be infrequent, with greater latitude for preservation and protection of cultural resources in place. Visual settings around significant sites would likely be unaltered. However, there might also be fewer opportunities to economically manage the vegetation adjacent to such sites. The accessibility of some sites managed for interpretive purposes would be limited to non-motorized means only.

A somewhat smaller number of acres than other alternatives would be inventoried for cultural resources. Approximately 422,000 acres over the planning period would be surveyed in support of the Forest timber program.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 40 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains the second highest level of habitat for mature and old growth species

Deer and elk populations are increased in both summer and winter habitat.

This alternative has only a slight decrease in primary cavity excavator habitat.

Riparian habitat is increased.

This alternative provides the second highest level of recreation use of wildlife.

State wildlife objectives will be met for elk winter habitat, deer, mountain goats, grouse, and spotted owls.

ALTERNATIVE F

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 224,000 acres of suitable spotted owl habitat in lands that are unsuitable for timber management or in allocations that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 13,526 acres originally allocated to full timber yield prescriptions and 47,806 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the plan. Numbers of catchable trout, by the second decade, are estimated to increase from a current level of 200,000 to 212,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1.401 million and 172,000 to 179,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is estimated to remain constant at current levels throughout the life of the plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices, which will maintain current habitat capability and should allow fairly natural stream processes to function resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that approximately \$340,000 of the annual habitat improvement program will be funded through appropriated monies and \$197,000 through Knutson-Vandenburg funds. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous

fish runs in the drainage. Resident trout habitat capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the fourth decade and would only increase slightly in the fifth decade. Permitted grazing use in the first decade is expected to average 23,000 AUM's, 25,500 AUM's in the second decade, and 31,500 AUM's in the fifth decade. Demand for cattle grazing would exceed supply by the end of the second decade, but demand for sheep grazing could be met in all decades. Actual permitted use would not exceed total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 97,627 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 13,314 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 59,396 acres of old growth. By the fifth decade there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 13.6 million (MM) cubic feet (76.0 MM board feet) and a Timber Sale Programmed Quantity of 14.6 MMCF (81.6 MMBF) per year for the first five decades. The long-term sustained yield for this alternative is 19.2 MM cubic feet

based on 421,265 acres of suitable timber lands. This compares to the past decade average annual volume sold of 187.5 MMBF and average volume harvested of 166.0 MMBF.

This alternative proposes higher intensity timber management on only 2% of the general forest acres. An additional 39 percent would be treated at the GF-3, or moderate intensity. The remaining acres would receive no thinning or other cultural treatment to improve timber growth.

An average of 869 acres per year will be clearcut, 2,515 acres will be shelterwood cut, and 1,692 acres will be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the *management activities proposed in each alternative*. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 8,700, 12,100 and 15,300 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades the activity related delivered sediment will be approximately 51,500 tons per year. By the end of the third decade, most of the roads will have been built so the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by 44 percent. Therefore, management activity created soil loss in the fifth decade will be approximately 28,800 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres or 39 percent of the Forest) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 3,689 additional acres from mineral entry, which is less than one percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 606,495 acres, or 28 percent of the total Forest acres. The following figure shows how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWALS	OPEN BUT WITH HIGHLY SENSITIVE RESTRICTIVE MANAGEMENT	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	32,288 acres or 27%	27,455 acres or 23%
Area classified prospectively valuable for oil and gas	530 acres or less than 1%	53,234 acres or 25%	152,090 acres or 72%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	76,787 acres or 36%	99,556 acres or 17%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	186,646 acres or 35%	238,142 acres or 45%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

This situation is similar to Alternative E. The land use allocations would indicate a lower number of proposals. However, the effect of the existing proposals must be considered. The estimate is that there would be 25 proposals with 3 proceeding to the license application stage.

ROADS

The implementation of Alternative F would require the construction of approximately 872 miles of additional road. Some 222 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 20 years. In addition to the roads currently open, it is expected that 10% of the new roads would be opened to public use by high clearance vehicles.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. Unplanned natural ignitions occurring in wilderness would be treated as prescribed fire until declared a wildfire. Human caused fires occurring in wilderness would require an appropriate suppression response. Prescribed fire from unplanned ignitions would be used extensively to maintain a natural environment.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,897 million dollars. An annual budget of 22.2 million dollars would be required for implementation. Revenues from Forest products would return 8.4 million dollars to the U.S. Treasury, 2.0 million dollars would be returned to local governments. Employment would decrease by 473 jobs and income would decrease by 13.3 million dollars from existing levels.

ALTERNATIVE F
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec Visitor Days	6,443,000
Annual dispersed recreation capacity		
- Roaded	Rec Visitor Days	19,588,000
- Unroaded		988,000
- Wilderness		1,060,000
<u>Roadless Management</u>		
Lands allocated to roadless management other than wilderness (RE-2a & 2b, RE-3, SI-1, SI-2, RN-1, WS-3)	Acres	473,147
<u>Wild and Scenic Rivers</u>		
Wild	Miles	86.5
Scenic	Miles	100.0
Recreational	Miles	51.5
<u>Water Quality and Quantity</u>		
Water yield increase	Acre Feet	8,700
Sediment increase index	Tons/Year	51,500
<u>Old-growth</u>	Acres	309,000
<u>Wildlife and Fish</u>		
Wildlife habitat management (EW-1)	Acres	148,189
Anadromous fish commercial harvest	Pounds	63,000
<u>Visual Quality Objectives</u>		
Area managed for - Preservation	Acres	843,281
- Retention	Acres	761,850
- Partial Retention	Acres	265,872
- Modification	Acres	160,125
- Maximum Modification	Acres	133,052
<u>Timber</u>		
Allowable sale quantity	Million Cubic Feet	13.6
Allowable sale quantity	Million Board Feet	76.0
Long-term sustained yield	Million Cubic Feet	19.2
Area of suitable timber land	Acres	421,265
<u>Range</u>		
Grazing capacity	Animal Unit Months	38,500
Permitted grazing	Animal Unit Months	23,000
Area of suitable grazing land	Acres	812,668
<u>Social/Economic</u>		
Present Net Value	Million Dollars	1,897
Annual cost to the Federal Government	Million Dollars	22.2
Annual revenues to the Federal Government	Million Dollars	8.4
Annual returns to Local Governments	Million Dollars	2.0
Change in employment	Number of Jobs	-473
Change in income	Million Dollars	-13.3

ALTERNATIVE G

This alternative is an attempt to balance the land allocations between amenity values and commodity production emphasis. Of the currently roadless areas outside of existing wilderness and the Alpine Lakes Management Area which are suitable for timber production, approximately half was allocated to roadless management with a heavy emphasis toward motorized recreation and the remainder was allocated to commodity production.

The Forest was assisted in the development of portions of this alternative by representatives of off-road vehicle users groups from throughout the State.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.
- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.

RECREATION SETTING

--Developed Recreation

The emphasis will be on bringing selected sites up to full service standards. Only those sites which have a history of heavy use, or where it is possible to convert all sites in a single drainage to full service sites, will be considered. Other popular sites will be maintained with very little improvement to existing facilities. Some expansion of existing full service sites will occur.

Because of the popularity of areas such as the Lake Creek-Devil's Backbone, North Fork of the Entiat, Devil's Gulch, Manastash Ridge, and Naches Basin for motorized trail use activity, some additional development of trailheads with camping facilities for motorized users will be needed to accommodate this use. These would be developed in cooperation with the State Inter-agency Committee but would be available for all users.

There will be some opportunity to improve and/or establish overlooks and scenic vistas in new roaded areas.

Ski areas that have current master plans and are considering expansion are: Mission Ridge, White Pass, and Stevens Pass.

--Dispersed Recreation

By the second decade, 18% of the Forest will provide unroaded recreation opportunities outside wilderness. This includes 5,724 acres Primitive, 100,128 acres Semi-Primitive Non-Motorized, and 277,762 acres Semi-Primitive Motorized Recreation Opportunity Spectrums (ROS).

In addition, there will be 43 percent of the Forest providing roaded recreation or 931,752 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrums combined.

Twenty-one of the 23 inventoried roadless areas will have all or a portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	10,918	0
Rock Creek	32,924	30,401	2,523
Twin Lakes	22,048	14,480	7,568
Canyon Creek	9,158	4,494	4,664
Heather Lake	11,067	2,502	8,565
Chelan	71,063	58,555	12,508
Entiat	71,254	67,098	4,156
Stormy	32,500	28,938	3,562
Slide Ridge	10,091	0	10,091
Devil's Gulch	25,186	19,737	5,449
Taneum	25,122	8,649	16,473
Manastash	8,798	4,748	4,050
Norse Peak Adj.	11,300	3,986	7,314
Quartz	8,756	8,438	318
Naneum	6,911	0	6,911
Lion Rock	4,834	4,558	276
William O. Douglas Adj.	22,938	1,378	21,560
Blue Slide	18,571	14,883	3,688
Goat Rocks Adj.	7,357	2,247	5,110
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining do not include 4,388 acres of dedicated old growth that fall within roadless allocations

ALTERNATIVE G

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1188.0
Unroaded Non-motorized	--	68.5
Unroaded Motorized	417.9	--
Roaded Motorized	788.4	--
Administratively Closed	--	352.8

Administratively closed trails are those trails in open allocations but closed for other environmental considerations

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>
Turnwater	Teanaway Nason Ridge Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

The White, Chiwawa and Wenatchee Rivers are recommended for designation under the Wild and Scenic Rivers Act. The proposed classifications are as follows:

River	Recommended Classification	Miles	Segment
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch
	Recreational	12.0	Above Tall Timbers Ranch to Lake Wenatchee.
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary.
	Recreational	24.0	Glacier Peak Wilderness boundary to Goose Creek.
	Recreational	6.0	Goose Creek to confluence with Wenatchee River
Wenatchee	Recreational	21.0	Lake Wenatchee to Tumwater Campground.
	Recreational	7.0	Tumwater Campground to Forest boundary.

The characteristics contributing to their eligibility will be protected until Congress formally determines the status of these rivers. Other eligible rivers on the Forest will not be recommended for inclusion in the Wild and Scenic Rivers System, but the corridors will be managed for Scenic Travel, with a visual quality objective of Retention. See Appendix E for a complete description of the Wild and Scenic Rivers analysis process

SCENERY

Visual quality would be maintained at a high level. All major interstate scenic highway viewsheds would retain a natural or slightly altered appearance. Visual quality in the Alpine Lakes Management Area would remain high.

All identified viewsheds and wilderness portals would retain a natural appearance.

Mad River, Table Mountain, Reecer Creek, and Chumstick Plain viewsheds would have high visual quality.

Cooper Mountain to South Navarre and the Little Rattlesnake viewsheds would have a reduced visual quality.

The majority of the landscape, including unroaded motorized areas, would be natural appearing. The remaining landscape viewed from Forest roads would have an altered appearance.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

Approximately 63 percent of the known cultural resources would be within management area designations having potential for a moderate to low level of impact. The visual settings around significant sites would likely be unaltered. There might be occasional conflicts with motorized trail use, requiring some level of mitigation.

The number of acres inventoried for cultural resources would be moderate (approximately 584,000 acres over the planning period would be examined in support of the timber program). There would be reasonable access to sites managed for interpretive purposes.

ALTERNATIVE G

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 56 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains moderate levels of habitat for mature and old growth species.

Deer and elk populations are increased in both summer and winter habitat.

This alternative provides a moderate level of primary cavity excavator habitat.

Riparian habitat is increased.

This alternative provides a moderate level of recreation use of wildlife.

State wildlife objectives will be met for elk winter habitat, deer, mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 187,000 acres of suitable spotted owl habitat in lands that are unsuitable for timber management or in allocations that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area

(SOHA) network, there were 16,918 acres originally allocated to full timber yield prescriptions, 42,464 acres originally allocated to reduced timber yields, and 29,871 acres originally allocated to prescriptions with no timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the plan. Numbers of catchable trout, by the second decade, are estimated to increase from a current level of 200,000 to 210,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1.368 million and from 172,000 to 174,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is estimated to remain constant at current levels through the life of the plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices, which will maintain current habitat capability and should allow fairly natural stream processes to function, resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that approximately \$17,000 of the annual habitat improvement program will be funded through appropriated monies and \$245,000 through Knutson-Vandenburg funds. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous fish runs in the drainage. Resident trout habitat capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the fourth decade and would only increase slightly in the fifth decade. Permitted use is expected to average 23,000 AUM's in the first decade, 25,500 AUM's in the second decade, and 33,500 AUM's in the fifth. Demand for cattle grazing would exceed supply by the end of the second decade, but demand for sheep grazing could be met in all decades. Actual permitted use would not exceed total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 77,063 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 17,829 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 75,391 acres of old growth. By the fifth decade there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 17.5 million (MM) cubic feet (98.0 MM board feet) and a Timber Sale Programmed Quantity of 18.7 MMBF (105.1 MMBF) per year for the first five decades. The long-term sustained yield for this alternative is 23.4 MM cubic feet based on 503,326 acres of suitable timber lands. This compares to the past decade average annual volume sold of 187.5 MMBF and average volume harvested of 166.0 MMBF.

Approximately 32% of the general forest area will receive intensive management including tree spacing (thinning).

An average of 1,124 acres per year will be clearcut, 3,139 acres will be shelterwood cut, and 2,131 acres will be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 11,200, 15,500 and 18,600 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-full service.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades, the activity-related delivered sediment will be approximately 60,900 tons per year. By the end of the third decade, most of the roads will have been built so the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by 44 percent. Therefore, management activity created soil loss in the fifth decade will be approximately 34,100 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres or 39 percent of the Forest) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 2,247 additional acres from mineral entry, which is less than 1 percent of the

ALTERNATIVE G

total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 536,513 acres or 25 percent of the total Forest acres.

The following figure shows how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWAL	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	26,903 acres or 22.5%	32,840 acres or 27.5%
Area classified prospectively valuable for oil and gas	530 acres or less than 1%	48,082 acres or 23%	157,242 acres or 74%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	62,074 acres or 10%	114,269 acres or 19%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	172,294 acres or 32%	252,493 acres or 47%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

The estimated activity level for small hydroelectric projects is 20 to 25 proposals with 3 proposals advancing to the application for license stage.

ROADS

The implementation of Alternative G would require the construction of approximately 1,160 miles of additional road. Some 458 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 20 years. In addition to the roads currently open, it is expected that 30 percent of the new roads would be opened to public use by high clearance vehicles.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

Fire hazard would increase due to a decrease of timber harvest in roadless areas. Prescribed burning would be used to maintain or enhance amenity values and to reduce the hazard in timber harvest areas. An appropriate suppression response would be made on all wildfires. Unplanned natural ignitions occurring in wilderness would be treated as prescribed fire until declared a wildfire. Human caused fires occurring in wilderness would require an appropriate suppression response.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,889 million dollars. An annual budget of 25.7 million dollars would be required for implementation. Revenues from Forest products would return 10.4 million dollars to the U.S. Treasury, 2.5 million dollars would be returned to local governments. Employment would decrease by 225 jobs and income would decrease by 6.54 million dollars from existing levels.

ALTERNATIVE G
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec. Visitor Days	6,623,000
Annual dispersed recreation capacity		
- Roaded	Rec. Visitor Days	20,999,000

Annual returns to Local Governments	Million Dollars	2.5
Change in employment	Number of Jobs	-225
Change in income	Million Dollars	-6 54

ALTERNATIVE H

ALTERNATIVE H

This alternative was developed to portray the maximum timber producing capability of the Forest under the present land allocations of existing management direction. This alternative has the same land allocations as Alternative A/NFMA. The major difference between this alternative and Alternative A/NFMA is that more intensive timber management would be practiced on the General Forest land allocation which would result in higher yields and higher annual sale quantities with a corresponding decrease in present net value.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.
- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.
- Changes in classification on some of the recommended Wild and Scenic Rivers and deletion of some eligible segments with private land issues.

RECREATION SETTING

--Developed Recreation

The emphasis will be on bringing selected sites up to full service standards. Only those sites which have a history of heavy use, or where it is possible to convert all sites in a single drainage to full service sites, will be considered. Other popular sites will be maintained with very little improvement to existing facilities. Some expansion of existing full service sites will occur.

There will be some opportunity to improve and/or establish overlooks and scenic vistas in new roaded areas.

Ski areas that have current master plans and are considering expansion are: Mission Ridge, White Pass, and Stevens Pass.

--Dispersed Recreation

By the second decade, 12% of the Forest will provide unroaded recreation opportunities which include 7,497 acres primitive, 58,032 acres Semi-Primitive Non-Motorized, and 183,825 acres Semi-Primitive Motorized Recreation Opportunity Spectrums (ROS).

ALTERNATIVE H

In addition, there will be 49 percent of the Forest providing roaded recreation, or 1,066,012 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrums combined.

Fifteen of the 23 inventoried roadless areas will have a portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	10,918	0
Rock Creek	32,924	17,935	14,989
Twin Lakes	22,048	13,717	8,331
Canyon Creek	9,158	0	9,158
Heather Lake	11,067	1,526	9,541
Chelan	71,063	59,806	11,257
Entiat	71,254	19,144	52,110
Stormy	32,500	0	32,500
Slide Ridge	10,091	0	10,091
Devil's Gulch	25,186	9,222	15,964
Taneum	25,122	6,296	18,826
Manastash	8,798	4,070	4,728
Norse Peak Adj.	11,300	2,650	8,650
Quartz	8,756	64	8,692
Naneum	6,911	21	6,890
Lion Rock	4,834	0	4,834
William O. Douglas Adj	22,938	784	22,154
Blue Slide	18,571	0	18,571
Goat Rocks Adj.	7,357	5,597	1,760
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 4,388 acres of dedicated old growth which fall within roadless allocations

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1188.0
Unroaded Non-motorized	--	94.4
Unroaded Motorized	235.7	--
Roaded Motorized	944.7	--
Administratively Closed	--	367.4

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>
Tumwater	Teanaway Nason Ridge Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

The American, Entiat and Waptus Rivers, and certain segments of the Cle Elum, Icicle, White, Napeequa, Chiwawa and Wenatchee Rivers are recommended for designation under the Wild and Scenic Rivers Act. The only eligible river not recommended for inclusion in the National System is the Little Wenatchee. However, the corridor here will be managed for a visual quality objective of retention, and fisheries habitat will be protected through special riparian prescriptions. For a more complete discussion of this topic, refer to Appendix E of the FEIS. The classification by segment is described in the following table:

ALTERNATIVE H

River	Recommended Classification	Miles	Segment
American	Wild	6.0	Headwaters to confluence with Rainier Fork.
	Scenic	16.0	Confluence with Rainier Fork to confluence with Bumping River (in Mather Memorial Parkway corridor).
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary.
	Recreational	24.0	Glacier Peak Wilderness boundary to Goose Creek.
Cle Elum	Wild	4.0	Headwaters to Alpine Lakes Wilderness boundary
	Scenic	2.0	Alpine Lakes Wilderness boundary to above Lake Tucquala.
Entiat	Wild	12.5	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	4.0	Glacier Peak Wilderness boundary to Cottonwood Trailhead
	Recreational	15.0	Cottonwood Trailhead to above Burns Creek.
Icicle	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary.
Napeequa	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
Waptus	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary
	Wild	1.0	Alpine Lakes Wilderness boundary to confluence with Cle Elum River.
Wenatchee	Recreational	7.0	Tumwater Campground to Forest boundary
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch.

The characteristics contributing to the eligibility will be protected until such time as action on these rivers is taken by Congress.

SCENERY

Visual quality would be maintained at a high level. All major interstate scenic highway viewsheds would retain a natural or slightly altered appearance. Visual quality in the Alpine Lakes Management Unit would remain high.

All major wilderness portals would retain a near natural appearance.

The landscape would have a natural to slightly altered appearance near major recreation areas and viewsheds. However, increased timber harvest and intensive management would result in an altered appearance in some areas. Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

Under this alternative, a majority of the known cultural resources (76 percent) would be within management area designations that may create a potentially moderate to high level of impact. These would require mitigation. Visual settings around some significant sites might experience modification apparent to the viewer. At the same time, opportunities would be good to enhance several significant historic sites through treatment of the adjacent vegetation in conjunction with the Forest timber management program.

There would be a high number of acres inventoried for cultural resources (approximately 604,000 acres over the planning period). Accessibility to cultural sites managed for interpretation would be very good.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the

freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 58 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains a low level of habitat for mature and old growth species.

Deer and elk populations are decreased a small amount in both summer and winter habitat.

This alternative provides a moderate level of primary cavity excavator habitat.

Riparian habitat is increased.

This alternative provides for moderate levels of recreation use of wildlife.

State wildlife objectives will be met for mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 151,100 acres of suitable spotted owl habitat in lands that are unsuitable for timber management or in allocations that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 16,430 acres originally allocated to full timber yield prescriptions and 41,955 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the plan. Numbers of catchable trout, by the second decade, are estimated to increase from a current level of 200,000 to 210,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1.368 million and from 172,000 to 173,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is estimated to remain constant at current levels through the life of the plan.

It is anticipated that increase in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices, which will maintain current habitat capability and should allow fairly natural stream processes to function, resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated approximately \$7,000 of the annual habitat improvement program will be funded through appropriated monies and \$245,000 through Knutson-Vandenburg funds. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous fish runs in the drainage. Resident trout habitat capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the fifth decade. Permitted use is expected to average 23,000 AUM's in the first decade, 25,500 AUM's in the second decade, and 36,000 AUM's in the fifth decade. Demand for cattle grazing would exceed supplies by the third

decade, but demand for sheep grazing would be met in all decades. Actual permitted use would not exceed the total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 55,863 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 22,854 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 91,567 acres of old growth. By the fifth decade there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 27.5 million (MM) cubic feet (146.7 MM board feet) and a Timber Sale Programmed Quantity of 28.9 MMCF (157.5 MMBF) per year for the first five decades. The long-term sustained yield for this alternative is 29.0 MM cubic feet based on 603,620 acres of suitable timber lands. This compares to the past decade average annual volume sold of 187.5 MMBF and average volume harvested of 166.0 MMBF.

Almost all general forest acres would be intensively managed including tree spacing (thinning) under this alternative. More shelterwood harvest is proposed under this alternative than under any other evaluated.

An average of 1,521 acres per year will be clearcut, 4,656 acres will be shelterwood cut, and 3,089 acres will be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 19,100, 27,300 and 28,900 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades, the activity related delivered sediment will be approximately 89,400 tons per year. By the end of the third decade, most of the roads will have been built so the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by 44 percent. Therefore, management activity created soil loss in the fifth decade will be approximately 50,100 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 1,717 additional acres from mineral entry, which is less than 1 percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 417,325 acres or 19 percent of the total Forest acres. The following figure shows how this management strategy would affect areas, identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWAL	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	23,914 acres or 20%	35,827 acres or 30%
Area classified prospectively valuable for oil and gas	0 acres or 0%	32,246 acres or 15%	173,608 acres or 82%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	56,774 acres or 9%	119,569 acres or 20%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	138,904 acres or 26%	285,884 acres or 53%

ALTERNATIVE H

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

Small hydroelectric proposal activity is estimated at 25 or more proposals, with 3 proceeding to the license application stage.

ROADS

The implementation of Alternative H would require the construction of approximately 1,550 miles of additional road. Some 652 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 16 years. In addition to the roads currently open, it is expected that 50% of the new roads would be opened to public use by high clearance vehicles.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. Unplanned natural ignitions occurring in wilderness would be treated as prescribed fire until declared a wildfire. Human caused fires occurring in wilderness would require an appropriate suppression response. Fire hazard will decrease because of increased timber harvest and hazard reduction activities. Fire prevention efforts would be directed toward timber harvest activities.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,864 million dollars. An annual budget of 28.9 million dollars would be required for implementation. Revenues from Forest products would return 12.9 million dollars to the U.S. Treasury; 3.1 million dollars would be returned to local governments. Employment would increase by 324 jobs and income would increase by 8.43 million dollars from existing levels.

ALTERNATIVE H
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec. Visitor Days	4,883,000
Annual dispersed recreation capacity		
- Roaded	Rec. Visitor Days	22,688,000
- Unroaded		1,021,000
- Wilderness		1,060,000
<u>Roadless Management</u>		
Lands allocated to roadless management other than wilderness (RE-2a & 2b, RE-3, SI-1, SI-2, RN-1, WS-3)	Acres	263,158
<u>Wild, Scenic and Rivers</u>		
-Wild	Miles	82.5
-Scenic	Miles	29.0
-Recreational	Miles	46.0
<u>Water Quality and Quantity</u>		
Water yield increase	Acre feet	19,100
Sediment increase index	Tons/Year	89,400
<u>Old-growth</u>	Acres	306,700
<u>Wildlife and Fish</u>		
Wildlife habitat management (EW-1)	Acres	17,151
Anadromous fish commercial harvest	Pounds	328,000
<u>Visual Quality Objectives</u>		
Area managed for - Preservation	Acres	842,751
- Retention	Acres	486,691
- Partial Retention	Acres	457,501
- Modification	Acres	55,629
- Maximum Modification	Acres	321,608
<u>Timber</u>		
Allowable sale quantity	Million Cubic feet	27.5
Allowable sale quantity	Million Board feet	146.7
Long-term sustained yield	Million Cubic feet	29.0
Area of suitable timber land	Acres	603,620
<u>Range</u>		
Grazing capacity	Animal Unit Months	36,800
Permitted grazing	Animal Unit Months	23,000
Area of suitable grazing land	Acres	893,642
<u>Social/Economic</u>		
Present Net Value	Million Dollars	1,864
Annual cost to the Federal Government	Million Dollars	28.9
Annual revenues to the Federal Government	Million Dollars	12.9
Annual returns to Local Governments	Million Dollars	3.1
Change in employment	Number of Jobs	+324
Change in income	Million Dollars	+8.43

ALTERNATIVE I

ALTERNATIVE I

Alternative I is a departure from the base sale schedule established under Alternative C, the preferred alternative. It has the same land allocation as Alternative C. The timber harvest schedule for Alternative C is based upon nondeclining flow, never exceeding long-term sustained yield. Alternative I has the same long-term sustained yield capacity as Alternative C but deviates from nondeclining flow. The level of timber harvest in the first decade approximates the average annual sell volume for fiscal years 1975 through 1984 under the current Timber Management Plan. The level of timber harvest gradually declines in the second and third decades, equaling that of Alternative C in the fourth decade. This would allow local industry to phase into a lower level of timber harvest more gradually than in Alternative C. The effects on other resources could be greater in the early decades due to the accelerated rate of timber harvest under the departure.

The major changes in this alternative from the DEIS, and the Supplement to the DEIS, include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.
- Revision of the mature habitat network for marten, and three-toed and pileated woodpeckers, by changing sizes, locations, and management direction.
- Increase inventoried roadless areage from 267,610 acres to 298,115 acres.
- Reduction in acres allocated to unroaded motorized use.
- Development and application of the Mather Memorial Parkway prescription (MP-1) which allows only unscheduled timber harvest within the Parkway corridor.
- An addition of two other allocations, EW-3 (Key Big Game Habitat, Unroaded) and RE-4 (Dispersed Recreation, Unroaded, Timber Harvest).
- Changes in the classification on some of the recommended Wild and Scenic Rivers.

RECREATION SETTING**--Developed Recreation**

This alternative places emphasis on upgrading and expanding heavily used popular campgrounds and renovating or rehabilitating facilities at other developed recreation sites. Highly popular reduced service campgrounds in developed high use areas, will be upgraded to full service sites. Campgrounds in more semi-primitive areas will remain as lesser developed sites. Facility repair in more remote semi-primitive settings will focus on sanitation, public safety and unserviceable facilities.

There will be some opportunity to improve and/or establish overlooks and scenic vistas.

Some small developed non-feet sites will still exist but as the facilities deteriorate beyond repair, the sites will be converted to dispersed occupancy spots.

Ski areas that have current master plans and are considering expansion are: Mission Ridge, White Pass, and Stevens Pass.

--Dispersed Recreation

By the second decade, 14% of the Forest will provide unroaded recreation opportunities outside wilderness. This includes 7,157 acres Primitive, 115,422 acres Semi-Primitive Non-Motorized, and 175,536 acres Semi-Primitive Motorized Recreation Opportunity Spectrums (ROS).

In addition, there will be 47 percent of the Forest providing roaded recreation or 1,017,251 acres of the roaded natural and roaded modified Recreation Opportunity Spectrums combined.

Twenty-two of the 23 inventoried roadless areas will have a substantial portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADED
Myrtle Lake	10,918	10,918	0
Rock Creek	32,924	22,812	10,112
Twin Lakes	22,048	14,331	7,717
Canyon Creek	9,158	4,197	4,961
Heather Lake	11,067	2,714	8,353
Chelan	71,063	63,664	7,399
Entiat	71,254	35,998	35,256
Stormy	32,500	9,710	22,790
Slide Ridge	10,091	2,502	7,589
Devil's Gulch	25,186	8,586	16,600
Taneum	25,122	7,038	18,084
Manastash	8,798	6,106	2,692
Norse Peak Adj.	11,300	1,357	9,943
Quartz	8,756	1,145	7,611
Naneum	6,911	1,335	5,576
Lion Rock	4,834	3,582	1,252
William O. Douglas Adj.	22,938	191	22,747
Blue Slide	18,571	3,032	15,539
Goat Rocks Adj.	7,357	1,293	6,064
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 6,232 acres of dedicated old growth that fall within roadless allocations

ALTERNATIVE I

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1188.0
Unroaded Non-motorized	--	139.7
Unroaded Motorized	245.1	--
Roaded Motorized	944.7	--
Administratively Closed	--	379.4

Administratively closed trails are those trails in open allocations but closed for other environmental considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>	<u>Old Growth</u>
Tumwater	Teaway Nason Ridge Annette Lake	Hornet Ridge Rattlesnake Springs Heather Lake Trailhead Fish Creek (Lake Wenatchee) The Sanctuary
<u>Ecological</u>	<u>Botanical</u>	<u>Geological</u>
Squaw Lake area Fish Lake Run Twin Lake Ponds Upper Naneum Meadow	Tumwater Ponderosa Estates Goose Egg Blue Slide	Boulder Cave Kloochman Rock Goose Egg Blue Slide

WILD, SCENIC, AND RECREATIONAL RIVERS

The American, Cle Elum, Waptus, Icicle, Napeequa, White, Chiwawa, Wenatchee, and Entiat Rivers are recommended for Wild and Scenic River designation. The proposed classifications are shown in the table below. The only eligible river not recommended for inclusion in the National System is the Little Wenatchee. However, the corridor here will be managed for a visual quality objective of retention, and fisheries habitat will be protected through special riparian prescriptions. For a more complete discussion of this topic, refer to Appendix E of the FEIS.

River	Recommended Classification	Miles	Segment
American	Wild	6.0	Headwaters to confluence with Rainier Fork.
	Scenic	16.0	Confluence with Rainier Fork to confluence with Bumping River (in Mather Memorial Parkway corridor).
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary.
	Recreational	24.0	Glacier Peak Wilderness boundary to Goose Creek.
	Recreational	6.0	Goose Creek to confluence with Wenatchee River.
Cle Elum	Wild	4.0	Headwaters to Alpine Lakes Wilderness boundary.
	Scenic	2.0	Alpine Lakes Wilderness boundary to above Lake Tucquala.
	Recreational	14.0	Above Lake Tucquala to Salmon La Sac bridge.
	Recreational	4.5	Salmon La Sac bridge to Lake Cle Elum.
Entiat	Wild	12.5	Headwaters to Glacier Peak Wilderness boundary
	Scenic	4.0	Glacier Peak Wilderness boundary to Cottonwood Trailhead
	Recreational	15.0	Cottonwood Trailhead to above Burns Creek
Icicle	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary
	Recreational	14.0	Alpine Lakes Wilderness boundary to above Leavenworth city water intake.
Napeequa	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Recreational	1.0	Glacier Peak Wilderness boundary to confluence with White River.
Waptus	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary.
	Wild	1.0	Alpine Lakes Wilderness boundary to confluence with Cle Elum River
Wenatchee	Recreational	21.0	Lake Wenatchee to Tumwater Campground.
	Recreational	7.0	Tumwater Campground to Forest boundary.
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch.
	Recreational	12.0	Above Tall Timbers Ranch to Lake Wenatchee.

The characteristics that contribute to the eligibility of these rivers will be protected until Congress formally determines their status.

ALTERNATIVE I

SCENERY

Visual quality would be maintained at a high level. All major interstate scenic highway viewsheds and the Alpine Lakes Management Unit will retain their natural appearance.

Most wilderness portals would retain a natural appearance.

Unnatural landscape patterns would dominate the Cooper Mountain to South Navarre, Little Naches, Cash Prairie, Little Rattlesnake, and North and South Fork Tieton viewsheds.

The balance of the landscape viewed from Forest roads would have an altered appearance.

Refer to Tables IV-5 and IV-6 in Chapter IV for specifics about future visual conditions of identified viewsheds and lakes.

Old growth preservation for aesthetic reasons are included in Old Growth (OG-1) and Special Interest (SI-2) prescriptions.

CULTURAL RESOURCE

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

A majority of the known cultural resources (77 percent) would be within management area designations that may create a potentially moderate to high level of impact. These would require mitigation. Visual settings around some significant sites might be difficult to manage in a natural appearing condition, particularly over the first four decades of the planning period. Opportunities would be good to enhance several significant historic sites through treatment of the adjacent vegetation in conjunction with the Forest timber management program.

There would be a moderate number of acres inventoried for cultural resources (approximately 577,000 acres over the planning period). Accessibility to cultural sites managed for interpretation would be very good.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 58 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains moderate levels of habitat for mature and old growth species.

Deer and elk populations are decreased in summer habitat and increased in winter habitat.

Primary cavity excavator habitat is maintained near the middle level of the alternatives.

Riparian habitat is increased.

This alternative is on the lower end of the range of alternatives for providing recreation use of wildlife.

State wildlife objectives will be met for deer, mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 165,100 acres of

suitable spotted owl habitat in lands that are unsuitable for timber management or in allocations that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 29,511 acres originally allocated to full timber yield prescriptions and 37,991 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the plan. Numbers of catchable trout, by the second decade, are estimated to increase from a current level of 200,000 to 216,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1.388 million and 172,000 to 177,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is estimated to remain constant at current levels through the life of the plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices, which will maintain current habitat capability and should allow fairly natural capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that approximately \$85,000 of the annual habitat improvement program will be funded through appropriated monies and \$367,000 through Knutson-Vandenburg funds. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objective to improve anadromous fish runs in the drainage. Resident trout habitat capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the fifth decade. Permitted use is expected to average 23,000 AUM's in the first decade, 24,000 AUM's in the second decade, and 24,000 AUM's in the fifth decade. Demand for cattle grazing would exceed supplies by the third decade, but demand for sheep grazing would be met in all decades. Actual permitted use would not exceed the total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 64,343 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 20,161 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 85,779 acres of old growth. By the fifth decade there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative is a departure from the base sale schedule established under Alternative C, the preferred alternative.

Alternative I has approximately the same long-term sustained yield capacity as Alternative C. However, unlike Alternative C, the allowable sale quantity in the first decade for Alternative I approximates the amount programmed for fiscal year 1989 (27.7 MM cubic feet or 154.6 MM board feet). The second decade timber harvest drops to 23.2 MM cubic feet. The Timber Sale Programmed Quantity for the first decade is 29.6 MMCF (166.0 MMBF). This compares to the

ALTERNATIVE I

past decade average annual volume sold of 187.5 MMBF and average volume harvested of 166.0 MMBF. The advantage of this alternative is that timber industry would have a 10 year period to adjust to lower sell levels. The disadvantage is that the sell level for decades 2 through 14 is less than that for Alternative C.

The long-term sustained yield for this alternative is 27.1 MM cubic feet based on 576,074 acres of suitable timber lands.

A wide range of timber intensities was selected, ranging from GF-1 (high level of timber investment) to GF-6 in General Forest Management Areas. Approximately 35% of the general forest area will receive intensive management including tree spacing (thinning).

An average of 5,603 acres per year will be clearcut, 223 acres will be shelterwood cut, and 2,913 acres will be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 17,300, 22,200 and 22,900 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades, the activity related delivered sediment will be approximately 71,400 tons per year. By the end of the third decade, most of the roads will have been built so the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by 44 percent. Therefore, management activity created soil loss in the fifth decade will be approximately 40,000 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres or 39 percent of the Forest) will not change in any of the alternatives, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 2,247 additional acres from mineral entry, which is less than one percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 482,876 acres or 22 percent of the total Forest acres. The following figure show how this management strategy would affect areas identified as having potential for the occurrence of locatable and leasable mineral resources.

	WITHDRAWALS	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	28,599 acres or 24%	31,143 acres or 26%
Area classified prospectively valuable for oil and gas	530 acres or 1%	44,330 acres or 21%	160,994 acres or 76%
Area classified prospectively valuable for geothermal resources	0 acres or less than 0%	58,767 acres or 9.8%	117,576 acres or 20%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	155,758 acres or 29%	264,030 acres or 50%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

Small hydroelectric proposal activity is estimated at 24 or more proposals, with 3 proposals moving to the application for license stage.

ROADS

The implementation of Alternative I would require the construction of approximately 1,493 miles of additional road. Some 713 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 16 years. In addition to the roads currently open, it is expected that 50% of the new roads would be opened to public use by high clearance vehicles.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

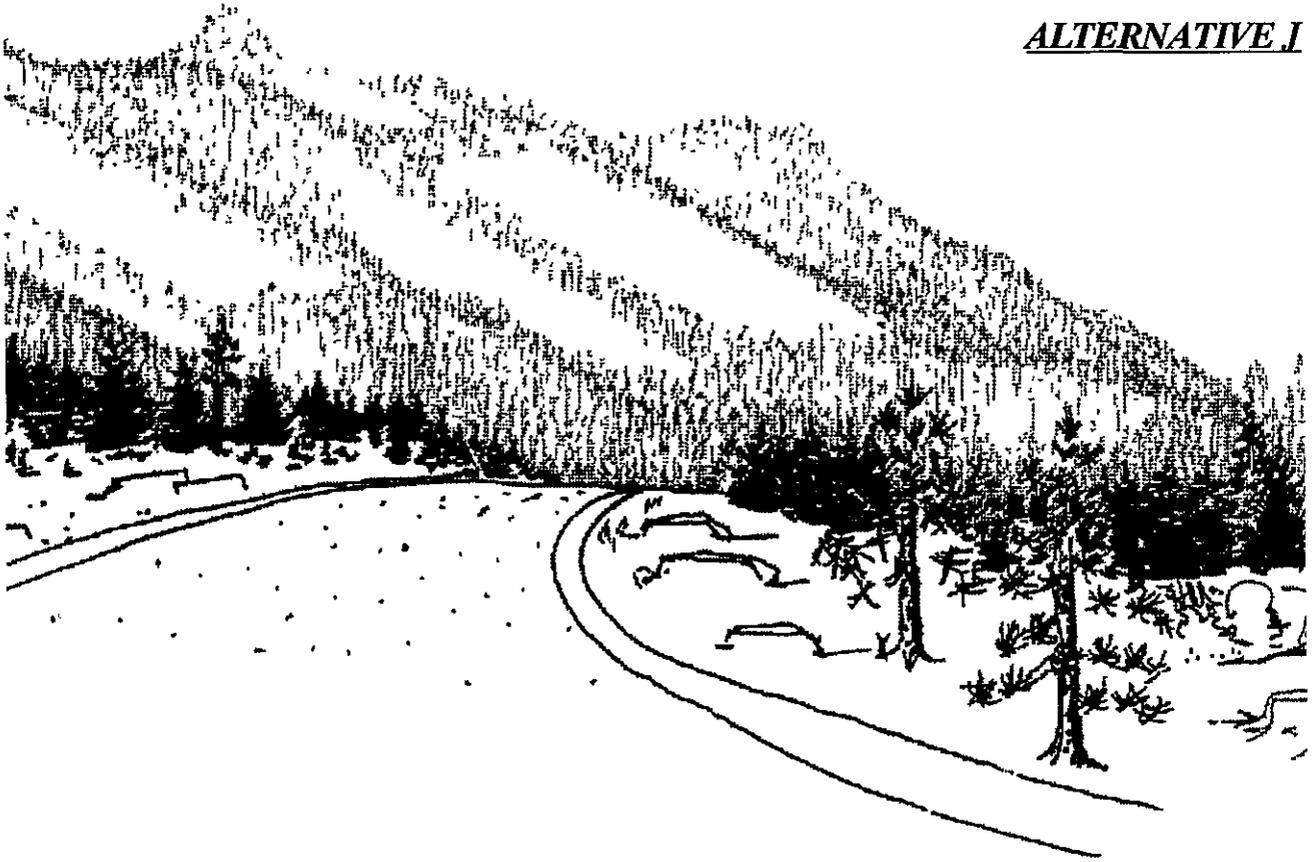

Prescribed fire would be used for reduction of activity fuels and for maintenance and improvement of other resources as a management tool. An appropriate suppression response would be made on all wildfires. Unplanned natural ignitions occurring in wilderness would be treated as prescribed fires until declared a wildfire. Human caused fires occurring in wilderness would require an appropriate suppression response.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,837 million dollars. An annual budget of 31.6 million dollars would be required for implementation. Revenues from Forest products would return 15.3 million dollars to the U.S. Treasury; 3.7 million dollars would be returned to local governments. Employment would increase by 413 jobs and income would increase by 10.86 million dollars from existing levels.

ALTERNATIVE I
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS
<u>Recreation</u>		
Annual developed recreation capacity	Rec Visitor Days	6,683,000
Annual dispersed recreation capacity		
- Roaded	Rec Visitor Days	21,889,000
- Unroaded		983,000
- Wilderness		1,060,000
<u>Roadless Management</u>		
Lands allocated to roadless management other than wilderness (RE-2a & 2b, RE-3, SI-1, SI-2, RN-1, EW-3, RE-4)	Acres	313,677
<u>Wild and Scenic Rivers</u>		
- Wild	Miles	82.5
- Scenic	Miles	29.0
- Recreational	Miles	118.5
<u>Water Quality and Quantity</u>		
Water yield increase -	Acre feet	17,300
Sediment increase index -	Tons/Year	71,400
<u>Old-growth</u>	Acres	307,300
<u>Wildlife and Fish</u>		
Wildlife habitat management (EW-1 & EW-3)	Acres	137,801
Anadromous fish commercial harvest	Pounds	328,000
<u>Visual Quality Objectives</u>		
Area managed for - Preservation	Acres	843,281
- Retention	Acres	521,800
- Partial Retention	Acres	332,927
- Modification	Acres	147,828
- Maximum Modification	Acres	318,344
<u>Timber</u>		
Allowable sale quantity	Million Cubic feet	27.7
Allowable sale quantity	Million Board feet	154.6
Long-term sustained yield	Million Cubic feet	27.1
Area of suitable timber land	Acres	576,074
<u>Range</u>		
Grazing capacity	Animal Unit Months	38,900
Permitted grazing	Animal Unit Months	23,000
Area of suitable grazing land	Acres	898,184
<u>Social/Economic</u>		
Present Net Value	Million Dollars	1,837
Annual cost to the Federal Government	Million Dollars	31.6
Annual revenues to the Federal Government	Million Dollars	15.3
Annual returns to Local Governments	Million Dollars	3.7
Change in employment	Number of Jobs	+413
Change in income	Million Dollars	+10.86

ALTERNATIVE J

This alternative was developed by representatives of the Timber Industry after release of the Wenatchee DEIS. They referred to it during the public input process as the "Essential Alternative." The goal of this alternative is to maintain timber harvest and other commodity outputs at their highest levels, while providing as much of the amenity outputs as possible without dropping ASQ below the level of the existing timber management plans.

Some features of this alternative include:

- The highest acreage of GF land allocation of any of the alternatives with correspondingly lower roadless and scenic travel allocations.

- No scenic travel retention allocation outside of the Alpine Lakes management area. I-90, Highway 2 (Stevens Pass) and Highway 97 (Swauk Pass) are in this management unit.

- Limited Partial Retention allocation on Mather, Entiat, Lake Wenatchee, and a part of the Chiwawa River road.

RECREATION SETTING

--Developed Recreation

The emphasis under this alternative is to convert the more popular reduced service recreation sites to full service status. Rehabilitation and renovation of high use sites will be accomplished to meet full service site standards. Other popular sites will be maintained with minor improvements to provide for sanitation and public safety. Some expansion of highly popular existing full service sites will occur.

Added coordination between the developed recreation component of the recreation setting is needed because of the increased timber harvest and road construction activities.

More opportunity will be available for establishing overlooks and opportunities to view scenic vistas in the new roaded areas.

Ski areas that are operating under existing master plan and are considering expansion are: Mission Ridge, White Pass, and Stevens Pass.

ALTERNATIVE J

--Dispersed Recreation

By the second decade, seventeen percent of the Forest will provide unroaded recreation opportunities outside wilderness. This includes 7,991 acres primitive, 150,664 acres semi-primitive non-motorized, and 222,196 acres semi-primitive motorized, Recreation Opportunity Spectrum (ROS) classes.

In addition, these will be 44% of the Forest providing roaded recreation or 951,524 acres of the Roaded Natural and Roaded Modified Recreation Opportunity Spectrum classes combined.

Fourteen of the twenty-three inventoried roadless areas will have a portion of their area maintained in a roadless management character. The area allocated to developed and roadless management is shown below.

AREA NAME	TOTAL ACRES PRESENTLY ROADLESS	ACRES REMAINING ROADLESS 1/	ACRES TO BE ROADDED
Myrtle Lake	10,918	8,968	1,950
Rock Creek	32,924	10,516	22,408
Twin Lakes	22,048	13,420	8,628
Canyon Creek	9,158	4,240	4,918
Heather Lake	11,067	1,442	9,625
Chelan	71,063	36,761	34,302
Entriat	71,254	25,355	45,899
Stormy	32,500	5,363	27,137
Slide Ridge	10,091	1,060	9,031
Devil's Gulch	25,186	0	25,186
Taneum	25,122	0	25,122
Manastash	8,798	0	8,798
Norse Peak Adj.	11,300	0	11,300
Quartz	8,756	0	8,756
Naneum	6,911	0	6,911
Lion Rock	4,834	3,859	975
William O. Douglas Adj.	22,938	0	22,938
Blue Slide	18,571	572	17,999
Goat Rocks Adj.	7,357	0	7,357
Nason Ridge	19,123	12,063	7,060
Alpine Lakes Adj.	44,393	28,513	15,880
Thorp Mountain	15,667	4,388	11,279
Teanaway	66,293	52,640	13,653

1/ The acres shown remaining roadless do not include 4,388 acres of dedicated old growth that fall within roadless allocations.

The miles of trail available to motorized use by land allocation or due to administrative closures are:

Allocation	Miles Open to Motorized Use	Miles Closed to Motorized Use
Wilderness	--	1188.0
Unroaded Non-motorized	--	66.7
Unroaded Motorized	162.5	---
Roaded Motorized	1045.6	---
Administratively Closed	--	390.0

Administratively closed trails are those trails in open allocations but closed for other resource management considerations.

--Special Interest Areas

The following proposed Special Interest areas would either remain classified or be recommended for classification for the purpose shown:

<u>Scenic</u>	<u>Dispersed Recreation</u>
Tumwater	Teanaway Nason Ridge Annette Lake

WILD, SCENIC, AND RECREATIONAL RIVERS

There are no rivers recommended for designation under the Wild and Scenic Rivers Act. River corridors would be subject to a full range of management activities, with five of the ten eligible rivers outside wilderness being allocated to timber harvest prescriptions that could noticeably alter the scenic qualities of the landscape.

SCENERY

Visual quality objectives would remain at a high level along the immediate foreground of all major interstate scenic highway travel routes, and most major wilderness portals. In this alternative a buffer strip of trees 200 feet along both sides of the travel route would be left slightly altered to altered. However, the viewshed beyond the 200 foot strip will be heavily altered.

Some wilderness and main transportation corridors will not maintain scenic qualities. Unnatural landscape patterns would occur in almost all major viewsheds.

The Alpine Lake Management unit will maintain high visual quality.

The general visual impression of the majority of the Forest would be a heavily altered landscape pattern. Block-cut patterns and contrasting openings will be dominant.

CULTURAL RESOURCES

Cultural resource inventory and evaluation, according to the established strategies and consultation procedures, would precede all ground disturbing projects. Appropriate historic preservation laws, regulations, and policies, plus the Forest-wide Standards and Guidelines, would direct future management decisions regarding significant cultural resources.

Approximately 80 percent of the known cultural resources would be within management area designations that may create a potentially moderate to high level of impact (59 percent would be within management areas that could be considered to have a high level of impact). These would require mitigation measures or frequent project modification. There might be noticeable modification of the visual settings around several significant sites. There might be an increase in the loss of non-significant sites.

ALTERNATIVE J

A high number of acres would be inventoried for cultural resources (approximately 644,000 acres over the planning period in support of the timber program alone), but the ways in which identified sites could be managed and interpreted in place might be constrained.

Coordination with the American Indian community would be ongoing to ensure that concerns regarding the protection of ancestral sites and the freedom to continue traditional religious uses of the Forest lands and resources are considered.

WILDERNESS

Wilderness would remain unchanged at 841,034 acres, or 39 percent of the Forest.

Increased emphasis will be placed on management, public information, and education on wilderness ethics and minimum impact camping techniques.

Approximately 62 percent of the land adjacent to the total length of wilderness boundary on the Forest is allocated to management activities associated with timber management and road access.

WILDLIFE

This alternative maintains low levels of habitat for mature and old growth species.

Deer and elk populations are decreased in summer habitat and increased a small amount in winter habitat. The wildlife habitat management prescriptions has different standards and guidelines in this alternative. See Appendix D for further information.

Primary cavity excavator habitat is maintained at low levels.

Riparian habitat is maintained.

This alternative is in the low range of providing for recreation use of wildlife.

State wildlife objectives will be met for deer, mountain goats, grouse, and spotted owls.

In this alternative, there are 149,000 acres of suitable spotted owl habitat in wilderness and Research Natural Areas, and 135,617 acres of suitable spotted owl habitat in lands that are unsuitable for timber management or in allocation that preclude timber management. Of the acres allocated to the Spotted Owl Habitat Area (SOHA) network, there were 41,510 acres originally allocated to full timber yield prescriptions and 23,384 acres originally allocated to reduced timber yields.

FISHERIES

This alternative should result in an increase in both anadromous and resident fish habitat capability through the life of the plan. Numbers of catchable trout, by the second decade, are estimated to increase from a current level of 200,000 to 217,000 fish. Spring chinook salmon and summer steelhead trout smolt habitat capability are estimated to increase from 1.348 million to 1.388 million and 172,000 to 177,000 smolts respectively. Summer chinook salmon and sockeye salmon smolt habitat capability is estimated to remain constant at current levels through the life of the plan.

It is anticipated that increases in habitat capability will result from Riparian Habitat Management Standards, the Fish Habitat Management Program and implementation of Best Management Practices, which will maintain current habitat capability and should allow fairly natural stream processes to function, resulting in improving trends in habitat capability. Further increases are expected due to implementation of a habitat improvement program. It is estimated that approximately \$45,000 of the annual habitat improvement program will be funded through appropriated monies and \$418,000 through Knutson-Vandenburg funds. This does not include potential funding through outside sources.

Actual anadromous fish outputs from the Forest will be dependent upon the success of other programs correcting problems such as passage off Forest. This alternative, however, is anticipated to improve habitat from current levels and thus is consistent with objectives to improve anadromous

fish runs in the drainage. Resident trout habitat capability will also improve, providing opportunities for expected increased demand for sport fishing.

RANGE

Permitted livestock grazing would increase in all decades through the fifth decade. Permitted use in the first decade is expected to average 23,000 AUM's, 25,500 AUM's in the second decade, and 36,000 AUM's in the fifth decade. Demand for cattle grazing would exceed supplies by the third decade, but demand for sheep grazing would be met in all decades. Actual permitted use would not exceed the total production potential by the fifth decade.

OLD GROWTH

This alternative would have approximately 148,507 acres of old growth in wilderness and 45,093 acres of old growth in prescriptions with no scheduled timber harvest. In areas within harvest prescriptions, but on lands unsuitable for timber harvest, there are approximately 25,970 acres of old growth. On suitable timberlands outside wilderness, in areas allocated for timber harvest, there are approximately 99,220 acres of old growth. By the fifth decade there will be a decline in total old growth acres mainly because old growth within harvest prescriptions will decrease, and ingrowth (when stands develop old growth characteristics over time) will not be rapid enough to replace the acres cut. The acres of old growth remaining will be of value for maintaining biological diversity, providing plant and wildlife diversity, and preserving aesthetic values.

TIMBER

This alternative would produce an Allowable Sale Quantity of 34.1 million (MM) cubic feet (173.8 MM board feet) and a Timber Sale Programmed Quantity of 36.5 MMCF (186.6 MMBF) per year for the first five decades. The long-term sustained yield for this alternative is 34.8 MM cubic feet based on 686,918 acres of suitable lands. This

compares to the past decade average annual volume sold of 187.5 MMBF and average volume harvested of 166.0 MMBF.

This alternative has the highest intensity of timber management. All suitable acres would be managed using thinning to increase yields of sawlog size trees.

An average of 8,050 acres per year would be clearcut, 2,215 acres would be shelterwood cut, and 5,133 acres would be selective cut.

WATER

Water quality and yield parameters are affected by the degree of commodity production. Refer to Chapter IV for a discussion of the variations in risks or benefits to water resources from the management activities proposed in each alternative. Water quality for this alternative should meet the Washington State Class AA (excellent) standard in all decades of the plan. Timber harvest activity in this alternative would result in annual water yield increases for the first, second and fifth decades of 29,100, 40,600 and 37,900 acre-feet, respectively, compared to a background annual runoff of 4,455,000 acre-feet.

SOIL

The background level (approximately 930,500 tons per year) of delivered sediment will remain constant throughout all decades. However, the amount of delivered sediment created by management activities related to timber manipulation will change over time. During the first and second decades, the activity-related delivered sediment will be approximately 96,600 tons per year. By the end of the third decade, most of the roads will have been built so the Forest should have a good transportation network in place. Because of this, it is anticipated that the amount of delivered sediment will be reduced by 44 percent. Therefore, management activity created soil loss in the fifth decade will be approximately 54,100 tons per year.

MINERALS

The area withdrawn as Wilderness (841,034 acres) will not change in any of the alternative, but the additional area to be withdrawn and the area to be managed under highly sensitive management prescriptions does vary by alternative. This alternative would result in the withdrawal of 2,247 additional acres from mineral entry, which is less than 1 percent of the total Forest acres. In addition to the withdrawals, highly sensitive management prescriptions which could discourage mineral related activities would be used to manage 365,046 acres or 17 percent of the total Forest acres. The following figure shows how this management strategy would affect areas identified as having potential for the occurrence of leasable.

	WITHDRAWALS	OPEN BUT WITH HIGHLY SENSITIVE MANAGEMENT STRATEGIES	OPEN WITH MODERATE TO LOW SENSITIVITY
"High" and "Moderate" locatable mineral potential areas	827 acres or less than 1%	23,236 acres or 19%	36,506 acres or 30%
Area classified prospectively valuable for oil and gas	530 acres or less than 1%	28,070 acres or 13%	177,254 acres or 84%
Area classified prospectively valuable for geothermal resources	0 acres or 0%	42,379 acres or 7%	133,964 acres or 22%
Area classified prospectively valuable for coal resources	869 acres or less than 1%	123,110 acres or 23%	301,678 acres or 56%

LANDS

Existing utility corridors would be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (e.g., 115 KV line might be increased to 230 KV). One potential new corridor is identified.

Small hydroelectric proposal activity is estimated at 25 or more proposals with 3 proceeding to the license application stage.

ROADS

The implementation of Alternative J would require the construction of approximately 1,964 miles of additional road. Some 1,006 miles of this construction is expected to take place in areas that are currently unroaded. It is assumed that the majority of this construction will occur in the next 18 years. All new construction and approximately 700 miles of existing road would be closed to public use by automobile.

The proposed construction and reconstruction of the Arterial and Collector roads are shown on Table IV-26 in Chapter IV.

FIRE MANAGEMENT

An appropriate suppression response would be made on all wildfires. Unplanned natural ignitions occurring in wilderness would be treated as prescribed fire until declared a wildfire. Human-caused fires occurring in wilderness would require an appropriate suppression response. Fire hazard will decrease because of increased timber harvest and hazard reduction activities. Fire prevention efforts would be directed toward timber harvest activities.

SOCIAL/ECONOMIC

Present net value of this alternative would be 1,825 million dollars. An annual budget of 33.8 million dollars would be required for implementation. Revenues from Forest products would return 8.7 million dollars to the U.S. Treasury; 2.1 million dollars would be returned to local governments. Employment would increase by 630 jobs and income would increase by 16.76 million dollars from existing levels.

ALTERNATIVE J
SUMMARY OF RESULTS RELATED TO PLANNING PROBLEMS (FIRST DECADE)

ISSUE	UNITS	RESULTS

^{1/} Alternative J has different standards and guidelines for EW-1 and Retention/Partial Retention acres than the other alternatives. Refer to Appendix D for more information.

2. COMPARISON OF ALTERNATIVES CONSIDERED IN DETAIL

a. OVERVIEW

This section will present the alternatives in a way that they can be easily compared. The aspects of the alternatives that will be presented for comparison include: responsiveness to issues and concerns, management areas, resource outputs, environmental effects, and costs and benefits. In addition to tables presenting information, there are narrative sections describing differences between alternatives.

The purpose of Forest planning is to identify and select for implementation that alternative that most nearly maximizes net public benefits. Net public benefits are defined as the

“... overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not . . . consistent with the principles of multiple use and sustained yield (36 CFR 219.3).

There is no mathematical formula available to define the preferred alternative. Indeed, there are differences of opinion about whether particular effects of alternatives are positive or negative. Therefore, it is necessary to separately identify all the major effects of each alternative as the basis for review, judgment, and an eventual selection. This selection may result in a completely different alternative or one that is a combination of those presented.

b. ISSUES AND CONCERNS

Alternatives are different ways of responding to issues and concerns. Table II-1 presents the ways that each alternative responds to each of the issues and concerns. Since benchmarks are analytic bases rather than attempts to respond to all issues, they do not appear in this table.

Each alternative has goals and output objectives. They are designed to respond to public issues and management concerns. Table II-1 presents the response of each alternative to the issues and concerns which are addressed differently in each alternative.

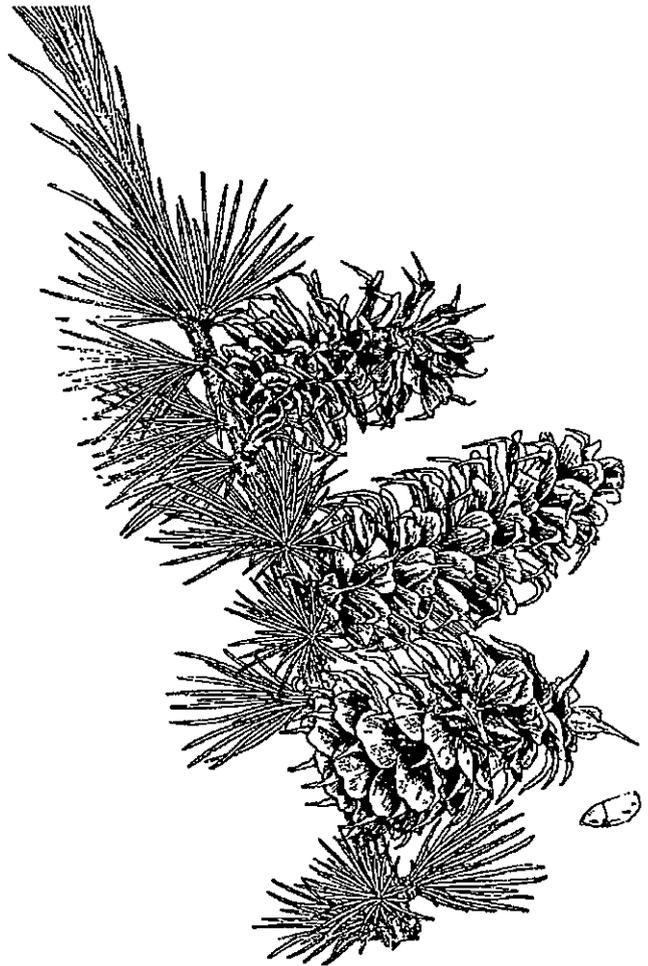

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

<u>ISSUES AND CONCERNS</u> <i>Outputs or Effects to be Measured</i>	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D					
<u>1 RECREATIONAL OPPORTUNITIES AND USE CONFLICTS</u> <i>Developed</i>	<p align="center">←—— The current potential supply of 2,900,000 Recreation Visitor Days (RVD's) at developed recreation sites is adequate to meet the projected demand on a Forest-wide basis regardless of alternative. However, as stated in Chapter III, there is demand and need to provide additional capacity in several specific areas such as the loicle drainage. To meet these needs, an additional 180,000 RVD capacity is planned for development through the year 2000. ———→</p>									
Ability to provide particular types of recreational use <u>Dispersed Allocations</u> <i>Roaded Acres</i> <i>Unroaded, Motorized Acres 1/</i> <i>Unroaded, Non-Motorized Acres</i>	1,148,131 175,015 0	1,066,012 183,825 65,529	1,086,321 139,177 89,868	1,017,251 175,536 122,579	1,086,321 139,177 89,868

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

ISSUES AND CONCERNS <i>Outputs or Effects to be Measured</i>	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D
Road densities and standards needed to implement the different land allocations of the Forest Plan Alternatives	←—————The assumptions about local road densities and standards are the same for all alternatives—————→ The amount of local road varies in direct proportion with the amount of timber harvest				
<i>Miles local roads</i>	Not Estimated.	1,462	1,883	1,468	1,612
5. WATER QUALITY, QUANTITY, AND TIMING OF FLOWS					
Measures that should be taken to maintain or enhance water quality. <i>Water Quality</i>	←—————The intent of all alternatives is to manage watersheds to minimize—————→ the loss of on-site soil productivity potential (e.g., minimize erosion and sedimentation) and to provide riparian area, stream channel, water quality and yield conditions that would protect the beneficial uses of water (e.g., fish habitat, irrigation). Measures designed to maintain or enhance water quality are incorporated in all alternatives through implementation of Standards and Guidelines and Best Management Practices				
The influence of land use allocations and activities on water yield <i>Water Yield</i>	←—————The potential effects of alternatives on water yield (quantity,—————→ timing of flows) are based on the acres allocated to prescriptions subject to vegetative manipulation through timber harvest (e.g., see "Water Yield" in Table II-3a). Refer to the Soil and Water sections of Chapter IV, Environmental Consequences, for further discussion of these issues				
6. MIXED OWNERSHIP MANAGEMENT					
Management of National Forest lands adjacent to other ownerships <i>There are no management prescriptions which apply to the NC alternative. The Forest will cooperate with adjacent land-owners and reasonable access will be provided.</i>	←—————In all alternatives these lands will be managed according to the management—————→ prescriptions applied to them. To the extent consistent with the prescriptions, the Forest will cooperate with the adjacent landowner in planning, road construction, and property line survey. In all cases, reasonable access will be provided to the private land owner, though the Forest Service may not share in the cost of access (e.g., within roadless areas in checkerboard ownership). Also, in some areas, delay of scheduled harvest of National Forest timber may be necessary to mitigate the cumulative effects of harvesting on both parties' lands.				

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

Alternative E	Alternative F	Alternative G	Alternative H	Alternative I	Alternative J
<p><-----The assumptions about local road densities and standards are the same for all alternatives-----> The amount of local road varies in direct proportion with the amount of timber harvest</p>					
830	872	1,142	1,532	1,475	1,945

<-----The intent of all alternatives is to manage watersheds to minimize----->
 the loss of on-site soil productivity potential (e g , minimize erosion and sedimentation) and to provide riparian area, stream channel, water quality and yield conditions that would protect the beneficial uses of water (e g , fish habitat, irrigation). Measures designed to maintain or enhance water quality are incorporated in all alternatives through implementation of Standards and Guidelines and Best Management Practices

<-----The potential effects of alternatives on water yield (quantity,----->
 timing of flows) are based on the acres allocated to prescriptions subject to vegetative manipulation through timber harvest (e g , see "Water Yield" in Table II-3a) Refer to the Soil and Water sections of Chapter IV, Environmental Consequences, for further discussion of these issues.

<-----In all alternatives these lands will be managed according to the management----->
 prescriptions applied to them. TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

ISSUES AND CONCERNS Outputs or Effects to be Measured	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D
Ability to meet fish habitat needs	<p>Riparian habitat management standards do not apply to this alternative. Protection of riparian and fish habitat will include only those measures necessary to meet the minimum requirements of the Washington State Forest Practice Rules and Regulations. This alternative has the lowest planned investment in habitat improvement and is the most risky in terms of not meeting fish habitat objectives.</p>	<p><—All Alternatives, except NC, should result in the protection and maintenance of—> fish habitat. Implementation of Forest-wide Fish and Riparian Standards, the EW-2 Prescription, Best Management Practices and Monitoring Guidance, should assure that fish habitat capability is at least maintained with an improving trend.</p> <p>Increases in habitat capability are also projected due to habitat improvement projects. Differences displayed between alternatives are due to the amount of money invested and the mix between KV funded work and projects projected to be completed with appropriated funds. It is assumed that eighty-percent of the appropriated funds will be spent on anadromous fish, with KV funding being split 50/50 between anadromous and resident fish work.</p> <p>Demand for fish is expected to increase over the life of the plan. By maintaining and improving habitat, all alternatives are compatible with objectives to increase anadromous fish production throughout the Columbia Basin. All alternatives should also provide increased opportunity for resident trout sport fishing.</p> <p>Projects the lowest increase in anadromous fish outputs by the second decade and the lowest investment in habitat improvement. Compared to other alternatives, Alternative A has a relatively moderate risk of not achieving fish habitat objectives.</p>	<p>Projects the sixth highest potential for anadromous fish outputs in the second decade with the fifth highest investment in habitat improvement. Due to the amount of land allocated to resource development activities such as timber management and roading, Alternative B has a relatively high risk of not achieving fish habitat objectives compared to other Alternatives.</p>	<p>Projects the third highest increase in anadromous fish outputs by the second decade. Along with Alternative B, it has approximately the fifth highest investment in habitat improvement. Due to the amount of land allocated to resource development such as timber management and roading, Alternative C has a relatively moderate risk of not achieving fish habitat objectives compared to other Alternatives.</p>	<p>Along with Alternatives G and H, Alternative D projects next to lowest increase in anadromous fish outputs by the second decade. It has approximately the lowest investment in habitat improvement. Due to the amount of land allocated to resource development activities such as timber management and roading, this alternative has a relatively high risk of not achieving fish habitat objectives compared to other alternatives.</p>

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

Alternative E	Alternative F	Alternative G	Alternative H	Alternative I	Alternative J
---------------	---------------	---------------	---------------	---------------	---------------

← All Alternatives, except NC, should result in the protection and maintenance of fish habitat. Implementation of Forest-wide Fish and Riparian Standards, the EW-2 Prescription, Best Management Practices and Monitoring guidance, should assure that fish habitat capability is at least maintained with an improving trend →

Increases in habitat capability are also projected due to habitat improvement projects. Differences displayed between alternatives are due to the amount of money invested and the mix between KV funded work and projects projected to be completed with appropriated funds. It is assumed that 80 percent of the appropriated funds will be spent on anadromous fish, with KV funding being split 50/50 between anadromous and resident fish work.

Demand for fish is expected to increase over the life of the plan. By maintaining and improving habitat, all alternatives are compatible with objectives to increase anadromous fish production throughout the Columbia Basin. All alternatives should also provide increased opportunity for resident trout sport fishing.

Projects the highest increase in anadromous fish outputs by the second decade with greatest investment in habitat improvement. Due to the amount of land allocated to resource development activities such as timber management and roading, this Alternative has a relatively low risk of not achieving fish habitat objectives compared to other Alternatives.

Projects the second highest increases in anadromous fish outputs by the second decade with the second highest investment in the habitat improvement. Due to the amount of land allocated to resource development activities such as timber management and roading, this Alternative has a relatively low risk of not achieving fish objectives compared to other Alternatives.

Along with Alternatives D and H, alternative G projects the fifth highest increase in anadromous fish outputs, with the seventh highest investment in habitat improvement. Due to the amount of land allocated to resource development activities such as timber management and roading, this Alternative has a relatively low risk of not achieving fish habitat objectives compared to other Alternatives.

Along with Alternatives D and G, alternative H projects fifth highest increase anadromous fish outputs with an investment in habitat improvement similar to alternative G. Due to amount of land allocated to resource development activities such as timber harvest and roading, this Alternative has a relatively moderate risk of not achieving fish habitat objectives.

Along with Alternatives B, alternative I projects the fourth highest increase in anadromous fish outputs with the fourth highest investment in habitat improvement. Due to the amount of land allocated to resource development activities such as timber management and roading, this alternative has a relatively moderate risk of not achieving fish habitat objectives. Because this is a departure alternative, alternative I is somewhat more risky than alternatives A, C, H.

Projects the fourth highest increase in anadromous fish outputs by the second decade with the third highest investment in habitat improvement. Due to the amount of land allocated to resource development activities such as timber management and roading, this alternative has a relatively high risk of not achieving fish habitat objectives compared to other Alternatives.

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

ISSUES AND CONCERNS <i>Outputs or Effects to be Measured</i>	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D
9 VISUAL RESOURCE MANAGEMENT Maintenance, enhancement, and restoration of the visual resource <i>Visual Quality</i>	High reduction in natural appearing landscapes	High in natural appearing landscapes	Substantial reduction in natural appearing landscapes	Moderate reduction in natural appearing landscapes	Greatly reduced in natural appearing landscapes
Management direction needed to maintain the key or unique visual resources of the Forest <i>Visual Quality</i>	High reduction in management direction that protects unique visual attributes	High in management direction that protects unique visual attributes	Substantial reduction in management direction that protects unique visual attributes	Moderate reduction in management direction that protects unique visual attributes	Greatly reduced in management direction that protects unique visual attributes.
10 TIMBER MANAGEMENT The Forest timber harvest level considering the local, regional, and national demand for timber products. <i>Allowable Sale Quantity (first decade)</i>	Allowable sale quantity is the same as the current Timber Management Plan	Allowable sale quantity decreases to 71% of current Timber Management Plan	Allowable sale quantity decreases to 99% of current Timber Management Plan	Allowable sale quantity decreases to 80% of current Timber Management Plan	Allowable sale quantity decreases to 84% of current Timber Management Plan.
The capability and suitability of the Forest to produce timber <i>Suitable Acres For Timber Management</i>	Suitable acres are the highest of any alternative. (787,751 acres plus 102,200 marginal)	Suitable acres are the sixth highest of any alternative. (591,794 acres)	Suitable acres are the third highest of any alternative. (681,186 acres)	Suitable acres are the seventh highest of any alternative (576,074 acres)	Suitable acres are the fourth highest of any alternative (643,639 acres)

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

Substantial increase in natural appearing landscapes.	High increase in natural appearing landscapes.	High increase in natural appearing landscapes.	Little reduction in natural appearing landscapes	Moderate to higher reduction in natural appearing landscapes	Substantial reduction in natural appearing landscapes
Substantial increase in management direction that protects unique visual attributes	High increase in management direction that protects unique visual attributes	High increase in management direction that protects unique visual attributes	Little reduction in management direction that protects unique visual attributes	Moderate to higher reduction in management direction that protects unique visual attributes	Substantial reduction in management direction that protects unique visual attributes
Allowable sale quantity decreases to 42% of current Timber Management Plan	Allowable sale quantity decreases to 44% of current Timber Management Plan	Allowable sale quantity decreases to 57% of current Timber Management Plan.	Allowable sale quantity decreases to 86% of current Timber Management Plan	Allowable sale quantity decreases to 91% of current Timber Management Plan	Allowable sale quantity increases to 102% of current Timber Management Plan
Suitable acres are the lowest of any alternative (410,935 acres)	Suitable acres are the tenth highest of any alternative (421,265 acres)	Suitable acres are the ninth highest of any alternative (503,326 acres)	Suitable acres are the fifth highest of any alternative (603,620 acres)	Suitable acres are the eighth highest of any alternative (576,074 acres)	Suitable acres are the second highest of any alternative (686,918 acres)

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

ISSUES AND CONCERNS <i>Outputs or Effects to be Measured</i>	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D
The effect timber management has on other resources and on meeting other multiple use objectives <i>The ability to meet other resource objectives</i>	Other resource objectives are not fully integrated into this alternative	Less dispersed old-growth habitat protection would be included in this alternative	Increased funding would be required to mitigate other resource effects from increased harvest	All other resource objectives can be met or exceeded under this alternative	Other resource objectives would be similar to Alternative B except less money would be invested in tree management
11 ENERGY Management of existing and future utility corridor needs.	<----- All alternatives provide the same opportunities ----->				
Energy conservation in meeting other resource goals <i>Net Energy Balance</i>	Not estimated	Provides the fifth highest net energy balance	Provides the ninth highest net energy balance	Provides the sixth highest net energy balance	Provides the seventh highest net energy balance
12 THE ROLE OF FIRE The role of naturally occurring fires to improve Forest conditions.	<----- An appropriate wildfire suppression response will be implemented under all alternatives. All natural ignitions occurring in Wilderness will be considered prescribed fires unless declared a wildfire, at which time an appropriate suppression response will occur ----->				
Use of prescribed fire as a tool to improve Forest conditions <i>Prescribed Fire</i>	There will be a slight decrease in the amount of prescribed fire.	There will be no significant change in the number of acres treated by prescribed fire	There will be a significant increase in the number of acres treated by prescribed fire	There will be no significant change in the number of acres treated by prescribed fire	There will be no significant change in the number of acres treated by prescribed fire
Control of the public user to reduce fire risk to acceptable levels	<----- All alternatives will emphasize the reduction of public user control needed to bring fire risk to acceptable levels with little variation between alternatives ----->				

TABLE II-1

COMPARISON OF ISSUE AND CONCERN RESPONSE BY ALTERNATIVE

Alternative E	Alternative F	Alternative G	Alternative H	Alternative I	Alternative J
Many other resource objectives and opportunities are foregone under this alternative. The effect on unroaded recreation is minimized under this alternative.	Protection of roadless recreation high, but other resource production including forage at low level.	Opportunities to achieve other resource objectives through timber sales at low level. Protection of resource values impacted by timber sales high.	Moderate level of other resource outputs and moderate mitigation from timber sale effects.	Little change from current resource outputs in the first decade. Decrease timber, and other resource opportunities associated with timber sales in future decades.	Increased funding would be required to mitigate other resource effects from increased harvest.

← All alternatives provide the same opportunities →

Provides the highest net energy balance	Provides the second highest net energy balance	Provides the fourth highest net energy balance	Provides the eighth highest net energy balance	Provides the third highest net energy balance	Provides the lowest net energy balance

I. MANAGEMENT AREAS

Each alternative is a combination of management areas where sets of management practices and activity scheduling occur. Table II-2 presents acreages of the management areas for each alternative in a format for comparison. The enclosed maps accompanying this FEIS provide both a brief description of each management area and show its location on the Forest.

Benchmarks are analytic tests of the quantitative outputs under different assumptions. While approximating what could be managed on the ground, they are not mapped to assure their feasibility and manageability. Therefore, no management areas are presented here for the benchmarks.

1. Management Area EF-1: Experimental Forest

a. GOAL STATEMENT:

Provide opportunities to study the effects of forest management and fire on vegetative, soil and water resources occurring on the east side of the Cascade Mountains. Maintain the area in a form that will not compromise the opportunities for research.

b. DESCRIPTION:

The Entiat Experimental Forest was designated under the authority of the Chief of the Forest Service in 1970. Burned by wildfire in 1970, and rehabilitated and reforested in subsequent years, the area has been the subject of numerous scientific investigations. Currently, the Experimental Forest is being managed for a wide range of multiple uses in coordination with the Forestry Sciences Laboratory in Wenatchee. Periodic monitoring will occur until vegetation reaches such a size as to have a significant effect on water production. New studies will be initiated at that time.

New objectives following the Entiat Burn in August 1970 were to study the effects of fire on complete hydrologic units.

2. Management Area EW-1: Key Deer and Elk Habitat

a. GOAL STATEMENT:

Manage deer and elk winter range to meet habitat requirements for sustaining maximum carrying capacity.

b. DESCRIPTION:

Deer and elk winter ranges are generally on the edge of the Forest, adjacent to or intermingled with, other land ownerships, at low elevations, south and/or east facing slopes with reduced snow depth and early melt-off of snow. Because of these conditions these areas are highly desired for winter and/or early spring recreation activities and dry out early to become high fire danger areas. These habitats have openings covering 10 to 60 percent of the area (used by big game for foraging), containing shrubs, grasses, and forbs with scattered conifer trees, and 20 to 80 percent covered by conifer stands (used by big game for cover). The quality of the forage and the amount of thermal cover combined with the amount of human disturbance are the factors that determine the carrying capacity of these areas for big game in winter.

3. Management Area EW-2: Riparian-Aquatic Habitat Protection Zone

a. GOAL STATEMENT:

Maintain and enhance riparian management areas to perpetuate their distinctive resource values to (a) achieve and maintain habitat conditions necessary to maximize long-term natural production opportunities for desired fish species, (b) maintain water quality that meets or exceeds State Standards and (c) provide diverse wildlife habitat

b. DESCRIPTION:

This prescription applies to the land and vegetation adjacent to fish bearing streams, lakes and wetlands. The Riparian Management Area (RMA) shall correspond to at least the recognizable area dominated by riparian vegetation (true

Riparian Zone) and sufficient upland area (influence area) to assure adequate protection to achieve riparian management objectives and standards. The minimum area of consideration is 100 feet horizontal distance from the ordinary high water line associated with both banks of Class I, II, and fish bearing Class III streams and the perimeter of lakes and wetlands.

Riparian Management Area boundaries and specific riparian management objectives will be established for all projects within an RMA. Riparian management objectives will be established based upon analysis of RMA habitat conditions, objectives and standards both within the sub-drainage (generally 1,000-10,000 acres) and at the project site.

Within Riparian Management Areas, management decisions will be made in favor of riparian dependent resources (water quality, fish and wildlife habitat) when conflicts exist with man's use.

Refer to the Forest-wide Standards and Guidelines for Riparian Areas for overall direction on the planning and administration of management activities in RMA's. The interim quantitative standards applicable to EW-2 are also listed under the heading RIPARIAN in the following prescription, along with some of the operational considerations associated with the standards (under "MANAGEMENT PRACTICE"). Refer to the "Administration" section in the Forest-wide Standards and Guidelines for Riparian Areas for a discussion of the use and refinement of these interim standards.

**4. Management Area EW-3:
Key Big Game Habitat/Unroaded**

a. GOAL STATEMENT:

Manage deer, elk, and mountain goat winter range and key summer range to meet habitat requirements for sustaining optimum carrying capacity in an unroaded setting.

b. DESCRIPTION:

Deer and elk winter ranges are generally at low elevations, on south and/or east facing slopes with reduced snow depth and early melt-off of snow. Because of these conditions, these areas are highly desirable for winter and early spring recreation activities, and dry out early to become high fire danger areas. These habitats have 10-60 percent of the area in openings (used by big game for foraging) containing shrubs, grasses, and forbs with scattered conifer trees, and 20-80 percent of the area in conifer stands (used by big game for cover). The quality of the forage and the amount of thermal cover combined with the amount of human disturbance are the factors that determine the carrying capacity of these areas for big game in winter. Mountain goat summer and winter ranges are generally adjacent to each other at high elevations, well within the Forest, and just above and below the line separating suitable and unsuitable timber harvesting stands. Summer range consists of dense stands of old conifer trees intermingled with small meadows that provide food and shelter. Winter range consists of open, steep, rocky ridges with grasses, forbs, and shrubs dominating a landscape containing scattered conifer trees. Human activity, reductions in winter habitat, and lack of quality forage in summer range limit the populations of mountain goats.

**5. Management Area GF:
General Forest**

a. GOAL STATEMENT:

Provide for the greatest long-term growth and production of commercially valuable wood products at a level of investment in timber culture practices that maximizes net public benefits.

b. DESCRIPTION:

Future stands will vary from intensive timber management typified by regular spacing, relatively even age and height, to those that are similar to natural stands. Regenerated stands will have a high ratio of genetically superior stock and may receive cultural treatments throughout the rotation. The cultural practices will be deter-

mined on a site specific basis depending on the biological and economic conditions of the stand. Regeneration harvest will generally occur at culmination of mean annual increment. Logging will be by the most economical methods compatible with silvicultural requirements, soil and water standards and landform. Road densities and standards would also be dependent upon these conditions. In the General Forest area, the relative intensity of management is set by the Forest Plan. However, site specific details and locations of treatments will be determined in the prescription written or field reviewed by a certified silviculturist.

**6. Management Area MP-1:
Mather Memorial Parkway**

a. GOAL STATEMENT:

Manage area to maintain and enhance its outstanding scenic and recreation qualities.

b. DESCRIPTION:

This is an area classified by executive order, encompassing a zone extending 1/2 mile each side of U.S. Highway 410, to be managed primarily for scenic and recreational purposes. Developments and management activities within the allocation generally are not visually evident. The natural existing or established landscape will generally have vegetation on forested lands that is composed of large old growth trees in the overstory or in groves intermixed with a variety of age classes in the understory. The general perception of the landscape is a natural appearing environment. Motorized use is permitted within these areas to the extent it is compatible with the management intent.

**7. Management Area OG-1:
Old-Growth Management**

a. GOAL STATEMENT:

Manage for old growth habitat to achieve "ecosystem diversity, preservation of aesthetic qualities", and/or wildlife and plant habitat".

b. DESCRIPTION:

The Regional Guide for the Pacific Northwest Region directs all Forests to use a standard definition of old growth. Following are the descriptions of the characteristics needed to meet the requirements of this prescription.

1. ECOSYSTEM DIVERSITY: Ecosystem diversity is a representation of the variety that exists in biotic communities and is characterized by the number of species on a site and by the number of communities at all sites. The variety of management prescriptions will provide many and varied stand conditions and species, helping to maintain ecosystem diversity in managed, younger stands. However, enough of all types of old growth are required to maintain species dependent on old growth and preserve the various kinds of old growth communities found on the Forest

2. PRESERVATION OF AESTHETIC QUALITIES: People using the forest for recreation purposes enjoy old growth trees for their aesthetic and awe-inspiring qualities. Old trees represent a living link with the past and provide an important visual reference to the natural successional process of the forest environment.

Old growth stands are typically thought of as having an atmosphere that is peaceful, cathedral-like, and park-like or an atmosphere of being small, closed in, dominated and encompassed. The stand feels cool and refreshing, and smells musty from the decaying vegetation (rotting logs, snags, fruiting bodies of fungus and underbrush). The trees have deep furrowed bark, large diameters at the base of the tree (generally 21" in diameter or larger), tall and straight boles, (over 100 feet tall) rotten cracks, broken limbs, mosses, lichens, and rounded tops that create the illusion of being old.

3. WILDLIFE AND PLANT HABITAT: The indicator species for old growth and mature habitat is the spotted owl. Habitat for spotted owls includes mature and overmature trees dominant in the overstory, a multi-layered canopy, trees of several age classes, large amounts of standing dead trees and down material present, canopy crown closure of 45 percent or greater, and elevations between 1500 and 5000 feet.

The 2200 acres (more or less depending upon local circumstances) of suitable habitat may be contiguous, or scattered over a area of about 9000 acres. There is usually unsuitable habitat (either naturally occurring or from harvest) intermingled with the suitable habitat. It is common to find logging activities next to suitable spotted owl habitat. Road use and recreation activities will often be taking place within the habitat site.

Maintenance of reproduction of spotted owls is of high concern. Therefore, limit activities that may affect reproduction will be limited.

**8. Management Area OG-2:
Mature Habitat**

a. GOAL STATEMENT:

Manage for mature to old growth habitat for wildlife and plant species dependent upon this habitat.

b. DESCRIPTION:

The indicator species for this prescription are the marten/northern three-toed woodpecker and pileated woodpecker. These indicators plus the spotted owl are designed to provide a mature and old growth network. The network is to provide habitat for all species dependent upon mature or old growth habitat. The habitat for the marten/northern three-toed woodpecker and pileated woodpecker is described as mature or overmature trees in the overstory, a multi-layered canopy of trees in several age classes, large amounts of dead standing and down trees present, and a canopy closure of 40 percent or greater. Habitat for marten/northern three-toed woodpeckers is at elevations of about 2000 to 7000 feet, and for the pileated woodpecker, about 1500 to 5000 feet in elevation.

The marten/northern three-toed woodpecker habitat is a 160 acre contiguous habitat. One site will be found every 4000 to 5000 acres and it will be overlapped with spotted owl and pileated woodpecker sites when possible. An additional 160 acres of habitat is needed for developing future marten/northern three-toed woodpecker habitat. This additional acreage may be in any

successional stages. The location of the 160 acres of mature habitat will change through time in the 320 acre site.

The pileated woodpecker habitat is 300 acres, made of stands of no less than 50 acres within a 1000 acre area. One site will be found every 12,000 acres and these sites should be overlapped with spotted owls when possible. An additional 300 acres of habitat is needed for pileated woodpecker sites that may be in any successional stage but must have a high number of snags to provide food. The location of the 300 acres of mature habitat will change through time in the 600 acre site.

**9. Management Area RE-1:
Developed Recreation**

a. GOAL STATEMENT:

Provide developed recreation in an Urban to Primitive Recreation Opportunity Spectrum (ROS) setting.

b. DESCRIPTION:

This prescription is applicable to existing and potential developed recreation sites within the full spectrum of ROS settings. The areas allocated to this use include only the specific site on which development takes place. This prescription is also applicable to existing and potential Alpine (downhill) ski areas including runs, tows or lift facilities, shelters, lodges, services and parking lots. Associated developments such as skating rinks, toboggan runs, etc , may also be present. Potential sites allocated to this prescription will be managed to protect or enhance the future values and conditions desired.

**10. Management Area RE-2A and RE-2B:
Dispersed Recreation, Unroaded, Motorized**

a. GOAL STATEMENT:

Provide dispersed, unroaded recreation in a semi-primitive motorized recreation opportunity setting.

b. DESCRIPTION:

This prescription is for application to unroaded areas in which trails are evident and maintained for the following types of uses:

RE-2A - Areas having existing or potential trails for motorbikes, hikers, and horseback riders.

RE-2B - Areas having existing or potential four-by-four routes in addition to trails for motor bikes, hikers and horseback riders.

They are generally located in a natural appearing landscape setting. Winter motorized use is permitted where appropriate.

**11. Management Area RE-3:
Dispersed Recreation, Unroaded,
Non-motorized**

a. GOAL STATEMENT:

Provide dispersed recreation in an unroaded, semi-primitive non-motorized setting or a primitive setting.

b. DESCRIPTION:

This prescription is for application to unroaded areas in which trails are evident and maintained for non-motorized uses. Landscape changes are generally not evident to those walking through the area. The area is essentially a natural or natural appearing environment. There is little evidence on-site of other users.

**12. Management Area RE-4:
Dispersed Recreation, Unroaded,
Timber Harvest**

a. GOAL STATEMENT:

Provide for dispersed recreation, as well as long-term growth and production of commercially valuable wood products at a very low level of investment in timber cultural practices while maintaining the unroaded characteristics.

b. DESCRIPTION

Approximately 90 percent of future stands would come from natural regeneration. The remaining 10 percent would be regenerated by planting, after failure of natural regeneration to establish the stand. No stand improvements are planned between regeneration and harvest, future stands will closely resemble unmanaged conditions and will be typified by a tendency towards small irregularly spaced groups. Stands will generally have poor crown ratios and a wide range of age and height. Mortality due to tree competition, disease, and insects can be expected. Logging will generally be by aerial system to protect the unroaded characteristics of the area. Roads will not be constructed, except to protect adjacent resources.

**13. Management Area RM-1:
Intensive Range Management**

a. GOAL STATEMENT:

Provide for maximum forage production and utilization by commercial livestock with a high level of investment in range cultural practices.

b. DESCRIPTION:

Management seeks to optimize production and utilization of forage allocated for livestock use consistent with maintaining the environment and providing for multiple use of the range. Cultural practices such as brush control or seeding may be combined with fencing and water developments to implement complex grazing systems.

**14. Management Area RN-1:
Research Natural Area**

a. GOAL STATEMENT:

Provide for; (1) Preservation of examples of all significant natural Ecosystems for comparison with those influenced by man, (2) educational research areas for ecological and environmental studies, and (3) preservation of gene pools for typical and rare and endangered plants and animals.

b. DESCRIPTION:

Research Natural Areas (RNA) contain either examples of typical natural ecosystems or unique kinds of vegetation, animals, and land which are reserved for scientific and educational use. This use is restricted to non-manipulative and non-destructive research. On the Wenatchee National Forest there are two established RNA's: Meeks Table and Thompson Clover. Two additional areas have been studied and are candidates for addition to the system. They are: Fish Lake Bog, a marsh-bog community, and Eldorado Creek, a montane serpentine community. Several new areas on the Forest are candidates as Research Natural areas to meet regional cell (ecosystem) needs. A Research Natural Area establishment report will be prepared for each recommended area when the Forest Plan is implemented. These reports will describe the boundaries of the areas. Until the reports are signed by the Chief of the Forest Service, the areas designated in this Plan are recommendations. They will be managed to maintain their suitability as RNA's.

**15. Management Area SI-1:
Classified Special Areas -
Scenic and/or Recreation**

a. GOAL STATEMENT:

Manage Special Areas for recreation use, substantially in their natural condition.

b. DESCRIPTION:

These areas are classified under 36 CFR 294.1 and managed for recreation use substantially in their natural condition. The purpose of classifying these areas is to protect the natural beauty and, where appropriate, foster public use and enjoyment of the feature or environment (scenic areas possess outstanding or unique natural beauty). They occupy large areas of land where some multiple use activities may be compatible. Motorized use is permitted within these areas to the extent it is compatible with the management intent. Developments such as resorts, parking areas, campgrounds, etc., are located outside of the Special Area whenever possible.

**16. Management Area SI-2:
Classified Special Area - Other**

a. GOAL STATEMENT:

Manage areas of significant cultural, geological, botanical, zoological, paleontological, or other special characteristics so as to protect, preserve, and enhance their intrinsic values.

b. DESCRIPTION:

Special Interest Areas are classified under 36 CFR 294.1 and managed for recreation use substantially in their natural condition. The purpose of classifying these areas is to protect, and where appropriate, foster public use and enjoyment of the feature or environment. This prescription includes the following:

1) Cultural-Historic Area: Lands possessing prehistoric or historical sites, buildings or objects of National Register significance or having special cultural associations to the American Indian community.

2) Geologic Area: Lands having unique geologic features of the earth's development including caves and fossils.

3) Botanical Area: Lands containing specimens or group exhibits of plants, plant groups and plant communities which are significant because of form, color occurrence, habitat location, life history, arrangement ecology, environment, rarity and/or other features.

4) Zoological Area: Those lands having authentic, significant, and interesting evidence of our American National heritage as it pertains to fauna. The areas are meaningful because they embrace animals, animal groups, or animal communities which are natural and important because of occurrence, habitat, location, life history, ecology, environment, rarity or other features.

5) Paleontological Areas: Areas containing relic specimens of fauna and flora. These are the plant and animals (nonhuman) that span geologic time between periods when life first appeared on earth

and the age of man. Significant specimens may include Precambrian rocks; shellfish; early vertebrates; coal swamp forests; early reptiles; dinosaurs and Cenozoic mammals.

Management of these areas is aimed at preserving the features and environment of the area to be classified. Developments such as resorts, parking areas, campgrounds, etc., are located outside of the special interest area whenever possible.

There is one classified special interest area on the Wenatchee National Forest - Tumwater Botanical Area. There are also several potential geologic areas and a number of known significant and potentially significant cultural sites. There may also be other special interest areas which have not been identified to date.

**17. Management Area ST-1:
Scenic Travel - Retention**

a. GOAL STATEMENT:

To retain or enhance the viewing and recreation experiences along scenic travel routes.

b. DESCRIPTION:

Development and permitted uses will meet the "Retention" Visual Quality Objective in foreground and middleground areas viewed from recreation sites, and designated roads and trails. Developments and management activities within the allocation generally are not visually evident. The natural existing or established landscape will generally have vegetation on forested lands that is composed of large old growth trees in the overstory or in groves intermixed with a variety of age classes in the understory. The general perception of the landscape is that of a natural appearing environment.

**18. Management Area ST-2:
Scenic Travel - Partial Retention**

a. GOAL STATEMENT:

Provide a natural appearing foreground and middleground along scenic travel corridors.

b. DESCRIPTION:

Development and permitted uses will meet the "Partial Retention" Visual Quality Objective in the foreground and middleground viewed from developed recreation sites and designated roads and trails. The foreground of the main use routes will generally have vegetation that is composed of some large trees in the overstory or in groves intermixed with a variety of age classes in the understory. The middleground viewed areas from the main travel routes will generally have the perception of a natural appearing environment. The proposed uses and vegetation management within the allocation will be integrated with the natural landscape so that activities are visually subordinate to the characteristic landscape.

**19. Management Area UC-1:
Utility Corridors**

a. GOAL STATEMENT:

Provide and manage utility corridors to accommodate energy transmission needs.

b. DESCRIPTION:

This prescription is applicable to existing and potential utility and transmission corridors. It includes the land directly under and adjacent to the pipeline or powerline facility (clearing limits). Compatible facilities are combined in the same corridor whenever possible. Resource uses, such as grazing, and dispersed recreation activities, such as camping, mushroom and berry picking, Christmas tree cutting, etc., may be compatible in some areas.

**20. Management Area WI-1:
Wilderness**

a. GOAL STATEMENT:

Preserve and protect the natural character for future generations, and provide opportunities for solitude, challenge, inspiration, and scientific study.

b. DESCRIPTION:

This prescription is for application to the following Wildernesses: Alpine Lakes, Chelan-Sawtooth, Glacier Peak, Henry M. Jackson, Norse Peak, William O. Douglas, and Goat Rocks. Also, refer to the Alpine Lakes Area Management Plan for specific direction for the Alpine Lakes Wilderness. Each wilderness is delineated into four wilderness Recreation opportunity classes. These classes are Pristine, Primitive, semi-primitive and transition. Each class represents a specific physical, biological, social and managerial setting and degree of isolation and solitude that can be experienced. Experiences range from the maximum solitude and freedom found in the Pristine Class to the more human impacted acres near wilderness boundaries and trailheads that are classified transition.

**21. Management Area WS-1:
Scenic River (Proposed)**

a. GOAL STATEMENT:

Preserve the Scenic River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

b. DESCRIPTION:

This prescription is for application to those river segments on the Forest that are free of impoundments, and have largely primitive watersheds or shorelines but are accessible by road in places.

**22. Management Area WS-2:
Recreational River (Proposed)**

a. GOAL STATEMENT:

Preserve the Recreational River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

b. DESCRIPTION:

This prescription is for application to those river segments on the Forest that are readily accessible by road or railroad, may have some development along their shorelines, and may have undergone some impoundment or diversion in the past.

**23. Management Area WS-3:
Wild River (Proposed)**

a. GOAL STATEMENT:

Preserve the Wild River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

b. DESCRIPTION:

This prescription is applicable to those river segments on the Forest identified as being free of impoundments and generally inaccessible except by trail, with watersheds or shoreline essentially primitive and waters unpolluted. These represent vestiges of primitive America.

1/ Acres not shown for Alternative NC as it does not have management areas. Roughly equivalent acres would be 841,034 for WI-1, 7,780 acres for Water, 1,081,049 acres for GF, 8,200 acres for RE-1, 36,337 acres for RE-2a, 276 for RN-1, 1,104 acres for SI-2, and 164,000 acres for ST-1

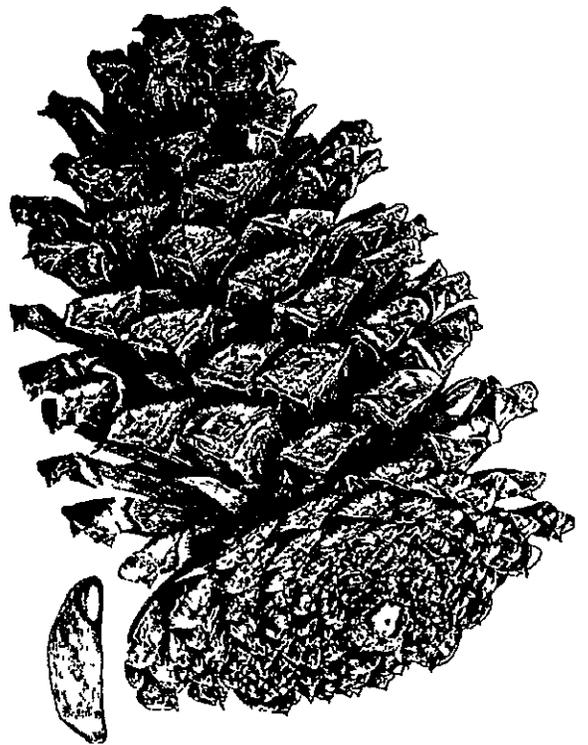

2/ Included in RE-2a.

3/ Acres distributed among other management areas

4/ WI-1 acreage totals include WS-3 acres (except 1,590 acres in Alt E, 1,442 acres in Alt F, and 170 acres in Alt. C and I)

J. RESOURCE OUTPUTS AND ENVIRONMENTAL EFFECTS

Many of the outputs and effects are derived from the analysis which is fully described in Appendix B. Environmental effects are more fully discussed in Chapter IV. Consult Appendix B and Chapter IV for additional information. By comparing the alternative's response to issues and concerns (Table II-1) and the outputs and effects (Tables II-3a and II-3b) in this Chapter, the relationship between issues and environmental effects can be seen. It is important to note that the outputs shown are estimates and projections based on available inventory data and assumptions, subject to the annual budget. Refer to the glossary for definitions and explanations of abbreviations and units of measure.

Mineral Exploration 1000 Acres						1,313.1					

FOOTNOTES

1/ Refer to the Glossary for definition of Units and Outputs

2/ Figures are "potential" capacities

3/ The figure for Decade 1 is the amount actually planned for this year. The others are average annual PAOT's

4/ Development will take place on these acres within the next 18 to 24 years, depending on the alternative

5/ The values reflect the estimated old growth acres by alternative and decade, but do not reflect any estimate for ingrowth (i.e. the development over time of stands that currently do not exhibit old growth habitat characteristics into stands that do). The amounts of old growth remaining would be relatively greater if ingrowth were included. Alternatives with lower harvest levels will develop old growth at a relatively higher rate.

6/ Assumes no areas for spotted owls are planned

7/ This is grazing capacity by alternative. Actual permitted grazing is not expected to exceed: First Decade - 23.0 MAUM's, Second Decade - 25.5 MAUM's, or Fifth Decade - 36.0 MAUM's, in some alternatives. Some alternatives will have less permitted use than others.

8/ Harvest volumes for Alternative NC are "potential yield" and include a 14.0 MMBF temporary inflation of the cut on the Naches Ranger District. Refer to Table II-3c for a further display of differences between the potential yield and other alternatives' ASQ.

9/ Estimated volume of fuelwood readily accessible is 14 percent of allowable sale quantity. Most of the accessible wood is logging residue and wood accessed by new timber sales.

10/ Average of FORPLAN for 13 decades

11/ Average of 2030 and 1990 from the plan

12/ The units shown are treated acres which are not indicative of the total area potentially affected by a given improvement project

13/ Area available with low to moderate sensitivity (acres). For accessibility data relative to mineral commodity information (eg, locatable minerals, energy minerals) and mineral potential ratings (eg, high, moderate, low, prospectively valuable), see the description of the alternatives considered in detail (this chapter).

14/ This figure was derived from the National Fire Management Analysis System as prepared for the Wenatchee National Forest. It is used to represent the most efficient level of protection identified in that process. The actual amount may vary significantly as there are changes in the values of resources and the costs incurred in fire suppression.

15/ Jobs and income figures are based on the actual timber volume harvested, not on the potential yield or volume sold.

16/ Includes "Land Suitable For Timber Production" plus lands that were tentatively suitable but not cost-efficient.

17/ Acres available for grazing include both currently suitable acres producing forage now and also those acres which will produce suitable transitory forage after trees have been harvested. Approximately one-half of the acres shown as available will be producing usable forage in any given decade. Acres shown for Alternatives NC, A/NFMA, C and F are acres within existing allotment only.

18/ Includes acres of clearcut and shelterwood regeneration cuts as computed by FORPLAN. Partial cutting acres are based on historic trends and 10 year action plans.

19/ Acres modeled in FORPLAN as clearcut. Includes some acres that may require shelter trees or, in extreme sites, unevenaged management to assure regeneration. Acres for Alternative NC are not modeled in FORPLAN.

20/ Acres of predominantly long rotation shelterwood - harvests. However, some clearcutting, and unevenaged management will be done based on site specific prescriptions by certified silviculturalists in consultation with various interdisciplinary specialists.

21/ Acres modeled in FORPLAN are labeled thinning but actually include overstory removal volumes as well. FORPLAN numbers do not include unestimated acres of salvage or unevenaged management as these were not modeled in FORPLAN. Historically, selective cutting included about 50 percent of the Forest acres harvested annually. Acres for Alternative NC are not modeled in FORPLAN.

22/ "Full Yield" includes GF-1, EW-1 and RM-1. For Alternative NC, Full Yield are the acres of "Standard" commercial forest land.

23/ "50 - 90 Percent of Full Yield" includes EW-2, OG-2, ST-1, WS-1 and WS-2. For Alternative NC, these are the acres of "Special" commercial forest land.

24/ The timber management plans upon which the No Change Alternative are based were developed in 1963 (Wenatchee) and 1969 (Naches). The plans were not integrated resource plans, and consequently did not address all resource uses and outputs. The missing information in this table cannot be reasonably estimated, since the original plans were based on yield tables and resource relationships which do not reflect the latest scientific techniques and information, do not reflect the standards in the NFMA regulations, or are otherwise inappropriate. Unit plans developed during the period 1976 to 1979 provided new standards and management objectives, which were used in on the ground management. Alternative A/NFMA - No Action is representative of the unit plans. Outputs and effects of all alternatives other than NC were calculated using updated inventories and yield tables and the latest methods of calculating timber harvest levels.

25/ This figure does not include all existing Forest Service administration withdrawals which are currently being reviewed per the requirements of the Federal Land Policy and Management Act of 1976. Those withdrawals cover approximately 7,627 acres (0.35% of the Forest), and have been included in the "Highly Sensitive" accessibility category of this table.

26/ These comparisons assume (1) Alternative "A/NFMA" is the base with which the other alternatives are varied, (2) a 1% decrease in the relative availability amount of area in withdrawals and/or highly restricted management prescription areas will result in a 1% decrease in production, (3) production of locatable minerals will come from areas identified as having a "moderate" to "high" potential for the occurrence of such, (4) production of energy minerals will come from areas identified to be prospectively valuable for these minerals.

TABLE II-3b

QUALITATIVE RESOURCE OUTPUTS AND ENVIRONMENTAL EFFECTS

Resource Outputs and Environmental Effects	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D
1 AIR QUALITY	<p>None of the alternatives allow significant degradation of air quality</p> <p>The Forest will comply with all applicable air quality laws and regulations and coordinate with appropriate regulatory agencies. To meet Regional Standards and Guidelines, the Forest will demonstrate reasonable progress in reducing total suspended particulates (TSP) from prescribed burning. There will be no significant effects on air quality upon implementation of any of the alternatives proposed in this plan. Effects of air quality on other resources will not vary significantly by alternative. Prescribed burning would be done when atmospheric conditions allow dispersal of smoke and minimize smoke entering populated areas. Occasional short-term deterioration will occur in limited geographic areas.</p>				
2 VISUAL CHARACTER OF THE FOREST	<p>All major interstate scenic highways, Lake Chelan, portals to most wilderness areas would have protection along the foreground, but would be heavily altered in the middleground and background. The narrow strip of 200 foot foreground in this alternative creates high risk for retaining visual quality. Partial cutting with longer rotations will reduce screenings along travel routes. An unnatural appearing landscape would dominate the majority of the Forest landscape.</p>	<p>All major interstate scenic highway viewsheds would retain natural or slightly altered conditions. All major portals to wildernesses would retain natural or slightly altered visual character. The natural appearance of the Forest as viewed from Forest roads would be altered to heavily altered. The Alpine Lakes Management Unit would retain high visual quality. The natural appearing landscape character would appear slightly altered to altered on most of the Forest landscape.</p>	<p>Most interstate scenic highway viewsheds would retain natural or slightly altered conditions. White Pass (Hwy-12) would be an altered viewshed. Only Lake Chelan viewshed would retain natural visual character of the portals to wildernesses. All other major portals to wildernesses would not retain natural appearing character. The natural appearance of the Forest as viewed from Forest roads would be heavily altered. The Alpine Lakes Management Unit would retain high visual quality. An unnatural appearing landscape character would dominate the majority of the Forest landscape.</p>	<p>All major interstate scenic highway viewsheds would retain a natural or slightly altered conditions. Most major portals to wilderness would retain a natural appearing character. Unnatural portals would be Cash Prairie and North and South Fork of the Tieton. The natural appearance of the Forest as viewed from Forest roads would be altered. The Alpine Lakes Management Unit would retain high visual quality. The natural appearing landscape character would appear slightly altered on most of the Forest landscape.</p>	<p>Most interstate scenic highway viewsheds would retain natural or slightly altered conditions. An altered viewshed would be White Pass (Hwy-12). Only the Lake Chelan viewshed would retain a natural appearing character. The natural appearance of the Forest as viewed from Forest roads would be heavily altered. The Alpine Lakes Management Unit would retain high visual quality. The unnatural appearing landscape character would dominate the majority of the Forest landscape.</p>
3 CHANGES IN RECREATION USE PATTERNS	<p>Current developed recreation use patterns would remain basically unchanged. Dispersed use would shift in accordance with the availability of unroaded areas and motorized/non-motorized opportunities as described below. Wilderness use opportunity is well distributed north to south along the western Forest boundary. Use may shift from older established areas to newer areas from visitors seeking a change or becoming acquainted with them.</p>	<p>Current developed recreation use patterns would remain basically unchanged. Dispersed use would shift in accordance with the availability of unroaded areas and motorized/non-motorized opportunities as described below. TABLE II-3b

QUALITATIVE RESOURCE OUTPUTS AND ENVIRONMENTAL EFFECTS

Resource Outputs and Environmental Effects	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D
Changes in Occupations & Employment	Increase of about 378 jobs from current situation. Approximately half of the jobs would be in the logging and wood processing sectors. The remainder would be primarily in wholesale and retail trade and the service sectors.	Increase of 39 jobs from 1982 Base Period Level. Logging and wood processing sectors decline by 132 jobs.	Increase of 577 jobs from 1982 Base Period Level. Logging and wood processing sectors increase by 137 jobs.	Increase of 203 jobs from 1982 Base Period Level. Logging and wood processing sectors decrease by 50 jobs.	Increase of 279 jobs from 1982 Base Period Level. Logging and wood processing sectors decrease by 12 jobs.
7 SOCIAL EFFECTS	←-----No measurable differences between alternatives-----→				
Population	←-----No measurable differences between alternatives-----→				
Lifestyles (Work and Leisure)	An increase of about 378 jobs from the current situation, with one-half of those jobs in rural woods products industrial communities (logging and wood processing). The remaining jobs would accrue in the wholesale and retail trade and service sectors. The altered appearance of the Forest would have adverse effects on rural recreational and residential communities and visitors from metropolitan areas. This alternative would be beneficial to other racial and cultural minorities, principally Hispanic Americans, owing to their participation in the increased general economic activity. Similarly, women would benefit from the increased economic activity.	Increase in employment in retail trade and service sectors. Decrease in logging and wood processing sectors. Adverse effects on rural communities with wood products industries. No effect on visitors from metropolitan areas or rural communities with tourism attractions.	Increase in employment in retail trade and service sectors. Increase in logging and wood processing sectors. Probable adverse effects with rural communities with tourism attractions and visitors from metropolitan areas. Positive effects on rural communities with wood products industries.	Increase in employment in retail trade and service sectors. Some decrease in logging and wood processing sectors. Positive effects on visitors from metropolitan areas and communities with tourism based economies. Some adverse effect on communities with wood products industries.	Increase in employment in retail trade and service sectors. Minor decrease in logging and wood processing sectors. Probable adverse effects on tourist based rural communities and tourists from metropolitan areas. Minor to no effect on communities with wood products industries.
Attitudes Beliefs and Values/ Expectations For Minimal Change	Land designations would not be consistent with people's beliefs and values. Adverse effects due to changes in local environmental amenities and recreational opportunities would conflict with what the American Indian community and other groups expect.	Land designations are generally consistent with people's beliefs and values. American Indian communities would benefit from improved protection of cultural sites, treaty right activities, and anadromous fish habitat.	Land designations would not be consistent with people's beliefs and values. Adverse effects due to changes in local environmental amenities and recreational opportunities would conflict with what the American Indian community and other groups expect.	Land designations are generally consistent with people's beliefs and values. American Indian communities would benefit from improved protection of cultural sites, treaty right activities, and anadromous fish habitat. Changes from current conditions would be minimal and occur gradually over time.	Land designations are generally consistent with people's beliefs and values. Changes would occur more rapidly in those areas designated for intensive timber management. The effects on American Indian beliefs and attitudes would be more intense in these areas.

QUALITATIVE RESOURCE OUTPUTS AND ENVIRONMENTAL EFFECTS

Resource Outputs and Environmental Effects	Alternative NC	Alternative A/NFMA	Alternative B	Alternative C Preferred	Alternative D
Community Cohesion	Community cohesion would be tested. There would be polarization on the roadless and scenery issues, and conflicts would intensify.	Community cohesion would be maintained. However, conflicts on the roadless area issue would intensify because of the loss of jobs.	Community cohesion would be tested. There would be polarization on the roadless and scenery issues, and conflicts would intensify.	Community cohesion is maintained. There would be increased conflict on the roadless issue and about sensitive scenic travel corridors, especially those near rural recreational and residential communities.	Community cohesion would be maintained. However, conflicts on the roadless issue would intensify because of the loss of jobs.
8 CIVIL RIGHTS	<-----The civil rights of individuals will be protected by all alternatives----->				
9 AMERICAN INDIAN	<-----Every alternative would involve continuing coordination with the American Indian community in accordance with the American Indian Religious Freedom Act. This will ensure that concerns regarding both the protection of ancestral sites and the freedom to continue traditional American Indian religious uses of the Forest lands and resources are considered. Until such time as specific use localities can be identified, the consequences of the individual alternatives cannot be determined, except to assume that the more intensive the level of modification the more likely is the alternative to adversely affect areas of potential significance to the American Indians.----->				
Treaty Rights	<-----Those rights reserved to the Indians of the Colville and Yakima Reservations by the Treaty with the Yakimas, June 9, 1855, will be honored in all alternatives----->				
(1) Anadromous Fisheries Treaty Rights	While best management practices would apply, Forest-wide Riparian and Fish Standards are not integrated into this Alternative and fish habitat improvement/rehabilitation is not emphasized. Because Alternative NC does not include Forest-wide Standards for fish and riparian habitat and because Alternative NC would allocate the most land to ground disturbing activities, this alternative has the highest risk of not meeting fish habitat objectives on the Forest.	<-----In all alternatives, except Alt. NC, the objective is to maintain and improve resident and anadromous fish habitat capability on the Forest. Each alternative includes Forest-wide Riparian and Fish Standards for managing fish habitat and includes expenditures for fish habitat improvement. Habitat improvement expenditures vary by alternative, but the net effect in each should be an improving trend in fish habitat capability.-----> Alternatives B, J and D allocate the most land to development activities such as timber management and roading and therefore have a relatively high risk of not meeting fish habitat objectives. Alternatives A, C, H and I pose a relatively moderate risk of not meeting habitat objectives, compared between Alternatives, while Alternatives G, F and E pose somewhat less risk. (See Chapter IV, Fisheries) Forest management of stream systems should maintain and improve habitat capability. Whether anadromous fish escapement to the forest and whether fish harvest attributable to fish produced on the Forest will increase will depend upon many factors. These revolve around programs aimed at improving fish runs in the Wenatchee, Entiat and Yakima Rivers and the Columbia Basin, such as the Northwest Power Planning Council's Fish and Wildlife program. With continued and improved coordination between the Forest Service and other groups and agencies which affect fisheries potential, long-term compliance with the Treaty is anticipated.			

TABLE II-3b

QUALITATIVE RESOURCE OUTPUTS AND ENVIRONMENTAL EFFECTS

Alternative E	Alternative F	Alternative G	Alternative H	Alternative I	Alternative J
In rural areas community cohesion would be strained because of the loss of jobs and unemployment in rural wood products communities. In metropolitan areas, the effects on cohesion are generally considered to be positive.	These effects are similar to those in Alternative E but would be less intense.	These effects are similar to those in Alternative E but would be less intense.	Community cohesion would be maintained. Some conflicts would likely develop because of the potential for reduced visual quality near rural recreational and residential communities.	Eastside urban areas and rural recreational and residential communities will experience more conflict and less cohesion because of the intensity of timber harvest in localized areas. People in metropolitan areas may experience concern because of the more intensive program with its attendant effects on unroaded areas and scenery.	Community cohesion would be maintained. However, conflicts on the roadless issue would intensify because of the loss of jobs.

←-----The civil rights of individuals will be protected by all alternatives----->

←-----Every alternative would involve continuing coordination with the American Indian community in accordance with the American Indian Religious Freedom Act. This will ensure that concerns regarding both the protection of ancestral sites and the freedom to continue traditional American Indian religious uses of the Forest lands and resources are considered. Until such time as specific use localities can be identified, the consequences of the individual alternatives cannot be determined, except to assume that the more intensive the level of modification the more likely is the alternative to adversely affect areas of potential significance to the American Indians----->

←-----Those rights reserved to the Indians of the Colville and Yakima Reservations by the Treaty with the Yakimas, June 9, 1855, will be honored in all alternatives----->

←-----In all alternatives, except Alt. NC, the objective is to maintain and improve resident and anadromous fish habitat capability on the Forest. Each Alternative includes Forest-wide Riparian and Fish Standards for managing fish habitat and includes expenditures for fish habitat improvement. Habitat improvement expenditures vary by Alternative, but the net effect in each should be an improving trend in fish habitat capability----->

Alternatives B, J and D allocate the most land to development activities such as timber management and roading and therefore have a relatively high risk of not meeting fish habitat objectives. Alternatives A, C, H and I pose a relatively moderate risk of not meeting habitat objectives, compared between Alternatives, while Alternatives G, F and E pose somewhat less risk. (See Chapter IV, Fisheries)

Forest management of stream systems should maintain and improve habitat capability. Whether anadromous fish escapement to the forest and whether fish harvest attributable to fish produced on the Forest will increase will depend upon many factors. These revolve around programs aimed at improving fish runs in the Wenatchee, Entiat and Yakima Rivers and the Columbia Basin such as the Northwest Power Planning Council's Fish and Wildlife program. With continued and improved coordination between the Forest Service and other groups and agencies which affect fisheries production and potential, long-term compliance with the Treaty is anticipated.

---	---	---	---	---	--

We are coordinating with various entities, such as State and local governments and Indian tribes, and none of the alternatives create direction which is in conflict with State and local controls and directions.

It has been determined by the U.S.D.A. Soil Conservation Service and confirmed by the Forest Service that there are no prime farmlands or rangelands on the Forest.

Prime forest land is a term used only for non-federal land and does not apply to Forest Service lands.

TABLE II-3b

QUALITATIVE RESOURCE OUTPUTS AND ENVIRONMENTAL EFFECTS

Alternative E	Alternative F	Alternative G	Alternative H	Alternative I	Alternative J
---------------	---------------	---------------	---------------	---------------	---------------

←-----The Riparian-Aquatic Habitat Protection Zone allocation (EW-2) is applied where vegetation manipulation can occur. Those alternatives which have the fewest acres in this allocation will offer the best protection for wetland and floodplains, because fewer acres are subject to timber harvest. Acres in this management area by alternative are as follows----->

38,012	40,832	47,573	52,301	47,361	52,470
--------	--------	--------	--------	--------	--------

The management standards and guidelines for this prescription in the plan provide better habitat for dependent species in the future than has been done in the past. Therefore, species dependent upon this habitat will be maintained or increase in numbers. This should provide more species for non-consumptive recreational use of wildlife.

←-----The area around the Wenatchee National Forest is one of the areas not meeting the recovery objectives in the State of Washington. The Forest is emphasizing bald eagle management by increasing the recovery goals for this species from 2 in the Draft EIS to 8 in the Final EIS to meet the recovery plan. There is 1 active nest on the Forest now and 2 others suspected----->

The Forest has been partially surveyed for peregrine falcons and there are a number of good potential nesting sites. In coordination with other groups, the Forest is participating in Falcon introductions. Therefore, it is likely that active nests sites will be on Forest in a few years. Habitat and plans for sensitive animals will be developed for maintaining these species.

←-----Big game management is gathering habitat inventories. Once this is done, the Forest can use existing models and research to provide populations of these species. The alternatives provide increases and decreases in both summer and winter range at various magnitudes. There are management problems that are specific to each area that will be resolved in the future----->

←-----There is a moderate to good inventory of spotted owl habitat and occupancy by spotted owls. The estimates of effects are fairly accurate. The marten and pileated woodpecker need inventories of habitat and populations to determine if the estimates are valid. The fifth decade estimate of numbers is near the lowest population levels of these species----->

←-----The Forest has many acres of habitat for these species in wilderness or roadless areas. Therefore the question is not if the Forest will provide a viable population but whether the Forest will maintain distribution of habitat and enough numbers for recreational use----->

←-----In the past decade, there were less people hunting than in previous decades. This trend is expected to continue. Therefore, there will be less need to provide big game for hunting in the future. There has been a six-fold increase in non-consumptive use of wildlife from 1975 to 1985. This is a large increase. The trend is expected to continue but not at the same rate as during the past 10 years. Management of wildlife in coordination with recreation will be more important than in the past----->

←-----These estimates of Diversity by alternative were derived by combining estimates for both plant and animal species as well as community diversity elements. The rating reflects the similarity of the diversity in an alternative to that found within the natural environment, therefore High indicates a high similarity to natural diversity. Estimates do not include invertebrates or non-vascular plants----->

High	High	Moderate-High	Low-Moderate	Low-Moderate	Low-Moderate
The American, Cle Elum, Icicle, Little Wenatchee, White, Napeequa, Chiwawa, Entiat, Wenatchee, and Waptus Rivers are recommended for inclusion in the Wild and Scenic Rivers System, at their highest potential classification. See Table IV-3 for proposed river classification.	The American, Cle Elum, Icicle, Little Wenatchee, White, Napeequa, Chiwawa, Entiat, Wenatchee, and Waptus Rivers are recommended for inclusion in the Wild and Scenic Rivers System, at their highest potential classification. See Table IV-3 for proposed river classification.	The Chiwawa, White, and Wenatchee Rivers are recommended for inclusion in the Wild and Scenic Rivers System. See Table IV-3 for potential river classifications.	The American, Waptus, and Entiat Rivers, and segments of the Cle Elum, Icicle, Chiwawa, White, Napeequa, and Wenatchee Rivers are recommended for inclusion in the Wild and Scenic Rivers System. See Table IV-3 for proposed river classifications.	The American, Cle Elum, Waptus, Icicle, White, Waptus, Chiwawa, Napeequa, Entiat, and Wenatchee Rivers are recommended for inclusion in the Wild and Scenic Rivers System. See Table IV-3 for potential river classifications.	No rivers are recommended for designation. River corridors would be subject to a full range of management activities, with potential for effects to outstanding river values and free-flowing characteristics.

TABLE II-3C
COMPARISON OF PAST, PRESENT, AND ALTERNATIVE TIMBER OUTPUTS
(MMBF/Year)

TIMBER OUTPUT COMPONENTS	1963 & 1969 TM PLANS POTENTIAL YIELD ^{1/}	1975-1984 AVERAGE VOLUME SOLD	ALTERNATIVES ^{3/}									
			A/NFMA	B	C <i>Preferred</i>	D	E	F	G	H	I	J
I ALLOWABLE SALE QUANTITY (ASQ) The allowable sale quantity is composed of those volumes resulting from the yield projections of FORPLAN ASQ is obtained from lands designated as suitable for timber production under NFMA standards, and meets the utilization standards in the Regional Guide. When sold, the volume is called "chargeable", and is used to determine achievement of planned allowable sale quantity goals ^{4/}	170.8 ^{2/}	159	121	169	136	143	72	76	98	147	155	170
II SAWTIMBER FROM LANDS DESIGNATED UNSUITABLE FOR TIMBER PRODUCTION - This incidental volume is an estimate of timber that will be sold from lands not designated for timber production. These sales are generally associated with vegetative management for other resources. Though meeting Regional Guide utilization standards, this volume is not considered "chargeable" against the planned allowable sale quantity goals ^{5/}	6.0	2	2.0	2.0	2.0	2.0	2.0	2.0	2.0	2.0	2.0	2.0
III SUBMERCHANTABLE VOLUMES FROM ALL LANDS - The estimated timber volume that does not meet the utilization standards in the Regional Guide, but which could be utilized for products other than sawtimber. It is not considered "chargeable" against planned allowable sale quantity goals ^{5/}												
A Fuelwood		4.4	3	5	3	4	2	2	2	4	4	4
B Other (Including Cull)		3.4	2	4	3	2	0	2	3	3	4	4
Total Submerchantable timber		7.8	5	9	6	6	2	4	5	7	7	9
TOTAL NET MERCHANTABLE SAWTIMBER	170.8	161	123	171	138	145	74	78	100	149	157	176
TOTAL NONCHARGEABLE	6.0	9.8	7	11	8	8	4	6	7	11	11	13
IV TIMBER SALE PROGRAM QUANTITY The timber sale program quantity includes the allowable sale quantity for the first decade and estimated additional volume planned for sale during the first decade, such as Fuelwood	176.8	169.6 ^{6/}	130	182	146	153	76	82	105	158	166	187

^{1/} The assumptions that were used in the existing timber management plan to calculate potential yield differ from those that were used to calculate Allowable Sale Quantity. While potential yield represented a level that could be produced, allowable sale quantity represents a timber objective and program for achievement of planned levels. However, both the potential yield and allowable sale quantity do represent a ceiling on the amount of chargeable timber volume that could be sold for a given decade. In this context, the two terms are comparable.

^{2/} Yield of timber projected for the period 1980 to 1989, as calculated for the 1963 & 1969 Timber Management Plans, revised in 1984. The potential yield is only that volume that is shown under Sawtimber (chargeable). Yield predictions are based on methods no longer used. The nonchargeable volume is marginal lands on the Wenatchee W.C.

^{3/} Allowable sale quantity calculated for the current land and resource management plan direction, projected into future using best available information for yield tables and suitability for timber harvest, and using the FORPLAN harvest scheduling model.

^{4/} Chargeable - wood that is attributed to Potential Yield (green and salvage) or Allowable Sale Quantity. ASQ includes salvage volume only when it otherwise would have been sound sawlog size volume. Examples are windthrow, fire kill, and widespread mortality from insect and disease.

^{5/} Non-chargeable - all volume not included in growth and yield projection for the selected management prescriptions used to arrive at Allowable Sale Quantity or the Potential Yield.

Existing Timber Management Plan

Data from the timber management (TM) plan---

1) Potential yield in million board feet 170 8

2) Average annual chargeable volume sold during years TM plan was in effect in million board feet 147 9

3) Total acres of standard, special and marginal lands used to develop the potential yield 889,951

Table II-3d displays timber resource management information by alternative and benchmarks. However, not all outputs are available for the benchmarks. This is because there were changes in alternative formulations and modeling parameters which resulted in the benchmark data displayed in the Draft EIS no longer being comparable to the alternatives displayed in the Final EIS. Refer to Appendix B for complete details.

The suitable acres displayed in column (1) in Table II-3d reflect the differences in acreage scheduled among alternatives. With few exceptions, the total suitable acres are a function of allocations which allow scheduled timber harvest. Those alternatives which have the highest timber volumes (NC, J, B, D) generally will have the highest number of suitable acres.

The beginning inventory is a function of the amount of suitable timber acres and species present on those suitable acres. In general, the more suitable timberlands, the greater the beginning inventory. The ending inventory decreases less in those alternatives with the smaller Allowable Sale Quantity (ASQ). Alternatives E and F have the lowest amount of suitable acres, inventory and ASQ primarily because of high allocations to roadless prescriptions.

The first decade ASQ reflects the amount of resource allocations, suitable timberlands, and departures from nondeclining flow. Alternatives J, B, and NC harvest the highest volumes primarily because of the largest amount of suitable acres but also because of high intensities of timber management. Alternative I, has the highest first decade harvest in proportion to the number of suitable acres because it is the departure alternative. Alternatives E, F, and G have the lowest ASQ's because of high allocations to roadless management.

The long-term sustained yield (LTSY), columns (8) - (10) reflect the suitable acres and management intensity of the timber harvest prescriptions in the alternatives. Alternatives with the highest ASQ, Alternatives J, B, and NC, achieve the LTSY in the first decade. An exception is Alternative I, which is the departure alternative. It uses the same land base as Alternative C but has a high ASQ the first decade, then declines, then eventually follows Alternative C. Alternatives A/NFMA and H have similar land allocations but H produces a level of

timber harvest that maximizes first decade harvest subject to nondeclining flow, while Alternative A/NFMA produces a level of timber harvest that maximizes present net value.

The average annual net growth for the first and fifth decades reveals a consistent pattern: the growth increase in every alternative. The gradual conversion of overmature or stagnated stands of timber to young, fast-growing seedlings and saplings explains this trend. The full growth potential isn't realized until LTSY is reached. Alternatives with low ASQ's (Alternatives E, F, G) and Alternatives with a lot of extended rotation harvest methods (A and H) tend to reach LTSY later and consequently do not reach their full growth potential immediately.

Acres on the Forest managed for full yield range from 87 to 32 percent, varying by alternative. Alternatives with the higher ASQ's generally have the higher amount of full yield acres and likewise have the greatest amount of acres clearcut in the first decade. Alternatives E and F, with the lowest ASQ's, also have the least amount of acres clearcut. An exception to the trend is Alternative I, the departure alternative. While it allocates the some percentages of acreage to full and 50-90% yield as Alternative C, it has the third highest amount of acres clearcut in the first decade in order to meet the departure harvest levels.

K. ECONOMIC EFFICIENCY **ANALYSIS OF ALTERNATIVES**

1. INTRODUCTION

Economic efficiency analysis is required by the National Forest Management Act Regulations (36 CFR 219) and plays an important role in the development and evaluation of benchmarks and alternatives. Specifically, the Regulations (36 CFR 219.12(f)) state that:

“The primary goal in formulating alternatives, besides complying with NEPA procedures, is to provide an adequate basis for identifying the alternative that comes nearest to maximizing net public benefits.”

This and following sections explain some of the key concepts and terms related to economic efficiency in general. Some of the significant differences between the alternatives and benchmarks with regard to their economic consequences and their responsiveness to the issues, concerns, and opportunities (ICO's) are also discussed. Please refer to Appendix B for a more detailed discussion of the process used to analyze economic efficiency for each of the benchmarks and alternatives considered during the development of this FEIS.

ECONOMIC EFFECTS

The purpose of this section is to display and compare the differences in economic costs and benefits of the alternatives, and to discuss the general reasons for these differences. More complete discussions of the relationship between economic values and net public benefits can be found in Chapter II, Major Tradeoffs Among Alternatives, and the Summary of Effects section in Appendix B.

COMPARISON OF COSTS AND BENEFITS

Table II-4 displays Present Net Value (PNV) and total discounted costs and benefits for the alternatives. PNV is the primary measure of economic efficiency used by the Forest Service. It is the sum of the priced benefits minus the sum of costs for the next 50 years, discounted to the present at the rate of four percent per year. An additional sensitivity analysis has been completed using a discount rate of 7-1/8 percent per year. Results of this analysis are shown in Appendix B.

The alternatives are ranked by decreasing present net value. Table II-5 displays the differences in PNV between adjacent pairs of successional ranked alternatives. The incremental changes in PNV are a measurement of the net economic values of the priced resources that would be foregone if a lower-ranked alternative is selected over a preceding one. This must be weighed against the nonpriced benefits of the alternatives.

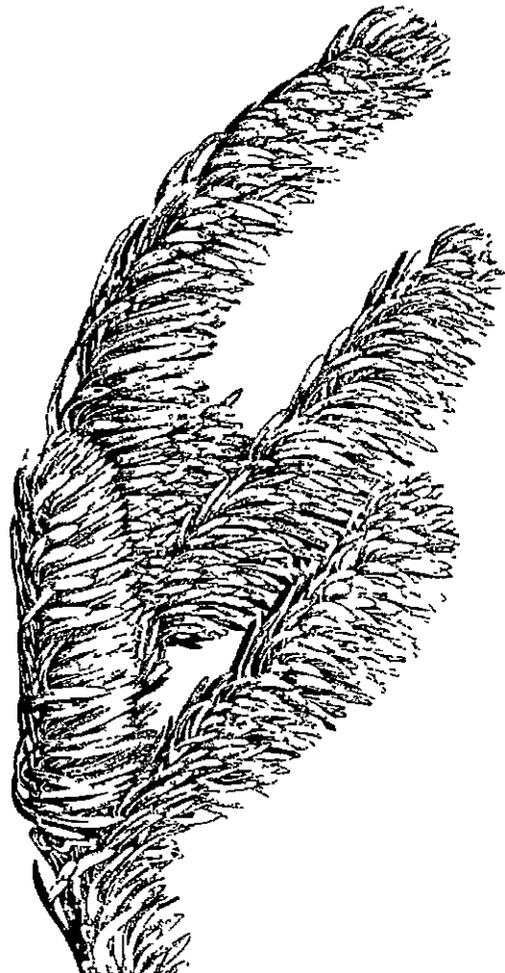

TABLE II-4
PRESENT NET VALUE AND DISCOUNTED COSTS AND BENEFITS OF ALTERNATIVES
(Million Dollars)

	Alternative/ Benchmark	PNV	Change	Discounted Costs	Discounted Change	Discounted Benefits	Discounted Change
	Max PNV	2,132		266		2,398	
(Current Mgt.)	A/NFMA	1,976	-156	329	-63	2,305	-93
	D	1,937	-39	410	+81	2,347	+42
(Preferred)	C	1,910	-27	409	-1	2,319	-28
	F	1,897	-13	312	-97	2,209	-110
	G	1,889	-8	371	+59	2,260	+51
	H	1,864	-25	435	+64	2,299	+90
(Departure)	I	1,837	-27	478	+43	2,315	+16
	E	1,834	-3	368	-110	2,202	-113
	J	1,825	-9	452	+84	2,277	+75
	B	1,756	-69	503	+51	2,259	-18
	NC	←-----Not Estimated-----→					

Alternative A/NFMA has the highest PNV at \$1,976 million. Alternative B has the lowest PNV at \$1,756 million. Alternatives A/NFMA, D, G, F, and E had a maximize PNV objective function in FORPLAN. Alternatives C, H, I, J, and B had either a timber volume target or were run under a maximize timber volume objective function in FORPLAN.

For the alternatives run under a maximize PNV objective function in FORPLAN, the greater the acreage allowing timber harvest the higher the PNV. The one exception is Alternative A/NFMA, which had a higher PNV because its recreation costs were significantly lower than for the other alternatives. The recreation benefits for Alternative A were similar to the other alternatives.

The present net values for Alternatives C, H, I, J, and B were directly related to the volume of timber produced in excess of the amounts that would maximize PNV for those alternatives' land allocations. That is, the value of the increased timber production in these alternatives is offset by less efficient production of timber.

Discounted costs equal the sum of all costs which would be incurred for an alternative during the 50 year planning horizon, discounted to their present values using a 4 percent discount rate. Alternative B has the highest discounted cost at \$503 million due to higher timber costs. As a general rule, costs were highest for those alternatives that produced the largest amounts of timber.

Discounted benefits equal the sum of all benefits which would be accrued for an alternative during the 50 year planning horizon, discounted to their

present values using a 4 percent discount rate. Alternative D has the highest discounted benefits at \$2,347 million. Alternative F had the lowest discounted benefits at \$2,187 million. Alternative D has the highest benefits because of its economically efficient timber harvest levels.

Table II-5 presents a more detailed breakdown of benefits and costs by resource groups. The alternatives are ranked in order of decreasing present net value. This display is only intended to give a broad indication of resource relationships. Many costs are nonseparable under multiple use management. It is difficult to attribute these costs to specific resources.

Resources having priced outputs are aggregated into groups for display in Table II-5. Timber refers to sawtimber. Recreation includes developed and dispersed recreation other than wildlife and fish related recreation. Wildlife includes wildlife and fish related recreation and commercially harvested anadromous fish. Range refers to permitted grazing. "Other" includes water yield.

Arterial and collector roads are shown as a separate costs item rather than being attributed to specific resources. Costs that were not clearly associated with a specific resource are included under "other."

Table II-5 reveals that almost all of the differences in present net value, discounted costs, and discounted benefits between alternatives is due to variations in the timber resource and changes in costs for the recreation and wildlife programs. The alternatives represent a wide range of timber harvest levels ranging from 81.6 MMBF to 186.6 MMBF for the first decade. With the exception of the departure alternative (I), discounted costs for timber rank in the same order as the timber harvest levels of the alternatives.

Present Net Value patterns are determined by whether the objective function in FORPLAN was maximize PNV or maximize timber volume objective or a timber volume target. Alternatives A/NFMA, D, E, F, and G had a maximize PNV objective function in FORPLAN. Alternatives B, C, H, I, and J had either a timber volume target or were run under a maximize timber volume objective function in FORPLAN. Alternative B was run under a maximize timber volume objective function to attempt to meet the RPA timber target assigned to the Forest by the Regional Guide for the Pacific Northwest Region. Alternative C had a 136 MMBF first decade target volume to meet local community needs. Timber harvest for Alternative H was set at the level which maximized timber production under the

1/Direct comparisons of benefits and costs by individual resource provide broad indications of relationships, but they may be misleading because many costs are nonseparable under multiple use management.

* Preferred

current land allocation in order to come as close as possible to the harvest level set by the Forest's current timber management plan. Alternative I is a departure alternative in which the first decade timber harvest is constrained to equal the average volume sold on the Forest from fiscal year 1975 to fiscal year 1984. Alternative J was run under a maximize timber volume objective function to reach a harvest level as close to 180 MMBF as possible. For all these alternatives, the timber volume level exceeds the PNV level. This results in higher harvest volume, but increases the ratio of costs to benefits. It is for this reason that the PNV's are lower for these alternatives.

Recreation benefits do not vary significantly between alternatives. All alternatives supply enough recreation capacity to exceed projected demand during the 50-year planning horizon. A shortage of unroaded recreation is projected for some alternatives beyond the planning horizon. The quality of the recreation experience would vary between alternatives even though the PNV benefits show little change. This effect was beyond the Forest's ability to quantify into dollar values and is considered as a nonpriced contribution to net public benefits. Recreation costs vary with the objectives of the alternative.

Wildlife and fish benefits vary slightly among alternatives due to different levels of investment in habitat improvements. The bulk of fish and wildlife benefits are recreation oriented and most of this recreation activity would occur regardless of the levels of investment in habitat improvement. The wildlife costs vary significantly by alternative. These costs are related to the goals and objectives for the alternative.

Range benefits and costs vary between alternatives. However, the differences are small enough that they are not reflected in Table II-5, where values are rounded to the nearest million dollars.

b. NET CASH FLOWS OF ALTERNATIVES

Table II-6 compares the expected cash flows to and from the United States Treasury that would be associated with the alternatives. Receipts are fees collected for sawtimber, firewood, grazing, developed camping, recreation and other special uses, and mineral leases. Costs include only

Forest Service budgetary costs. Net receipts equal total receipts less total costs. Non-cash benefits to the user are the difference between priced benefits and receipts actually collected for goods and services.

Alternatives are ranked by decreasing net receipts in Table II-6. All alternatives have negative net receipts for the first and fifth decades. This indicates negative net cash flows to the United States Treasury. Net receipts range from -10.5 million dollars for Alternative A to -26.1 million dollars for Alternative B for the first decade. Net receipts improve significantly by the fifth decade, but are still negative. Alternative B net cash flow improved to -1.4 million dollars, while Alternative I had the worst cash flow at -14.2 million dollars.

The reason for the negative cash flow is that both recreation and wildlife programs produce substantial benefits for which no revenue is collected for the Federal Government. For recreation, the only receipts are generated from campground fees and recreation special uses, all other users do not pay fees to the Federal Government. Likewise, the wildlife program produces substantial benefits for which no fees are collected. As Exhibit 3 indicates, non-cash benefits to users total approximately 81 million dollars for the first decade and 115 million dollars for the fifth decade. For the timber program, the variation in receipts is due to the differences in the volume, species mix, and size of timber harvested. The variation in costs is due to differences in the volume, location, and silvicultural system of timber harvested. In the first decade, all alternatives except B and J produce positive net receipts. Alternatives B and J have high costs and lower unit values in the first decade than other alternatives. By the fifth decade, the timber program is producing positive net receipts for all alternatives. The alternatives with the largest net cash receipts in the fifth decade are Alternatives B and J as a result of the large investments in the timber program in the first decade.

Total receipts are higher for the fifth decade than for the first decade. The general trend is for the alternatives to harvest more valuable timber in the future due to the assumption that timber will increase in real value by one percent a year for the next 50 years. Costs tend to be stable to somewhat lower in the future, primarily due to lower capital investments for roads. Non-cash benefits also increase due to increased recreational use, grazing, and wildlife and anadromous fish production.

Receipts plus non-cash benefits exceed costs in all alternatives for all decades.

L. MAJOR TRADEOFFS AMONG ALTERNATIVES

This section summarizes the relationships among economic values, community effects and the differing responses among alternatives to selected issues, concerns, and opportunities (ICO's). The purpose is to highlight major economic and noneconomic tradeoffs, or differences between alternatives, that can be quantified as indicators of response to ICO's among alternatives. However, a complete understanding of differences among alternatives requires reading all of this chapter and Chapter IV. Appendix A discusses the ICO's in greater detail.

To provide a partial framework for assessing these tradeoffs, the long-term resource demands or needs of the nation, region, and local communities are briefly summarized. Then selected economic values and quantified indicators of responsiveness to major ICO's are tabulated. Finally, differences and similarities among individual alternatives are summarized in terms of major tradeoffs among competing objectives or responses to expressed public issues, management concerns, or resource use and development opportunities.

1. NATIONAL, REGIONAL AND LOCAL OVERVIEW

The Draft Environmental Impact Statement for the 1985 Resources Planning Act Program estimates that total national demands will rise for all outputs of the National Forests. At the same time, there is a strong demand to protect and enhance the quality of the environment.

The Regional Guide for the Pacific Northwest Region estimates that demands for all outputs of the National Forests will rise in the States of Oregon and Washington. Recreation use is expected to increase as the population increases and its characteristics change. The Pacific Northwest has a much greater ratio of public forest and range lands to population than most of the country. The bulk of recreation use is expected to be from residents of the region. Demand for wilderness recreation is expected to exceed what

can be supplied within the Wilderness Preservation System regionally. Demand could be met in the near future, at least, by utilization of undeveloped lands outside of the Wilderness Preservation System. Development of these lands would intensify pressure on the formally designated wilderness.

Although the regional demand for hunting is expected to increase, the local demand for big game hunting is decreasing slightly while demand for other game is remaining constant. These trends have been documented by Washington State Department of Wildlife. The local demand for nonconsumptive use of wildlife is rapidly increasing due to public desires to view wildlife. This local increase is comparable to national and regional studies.

Demand for livestock grazing is expected to increase at a faster rate in the Pacific Northwest than nationally. Additional demands for natural range forage are stemming from loss of feedlot opportunities due to increasing costs.

The National Forests of the Pacific Northwest supply almost one-half of the sawtimber of the entire National Forest System. The quantity of timber demanded regionally in the year 2000 is expected to be only one percent greater than the 1976 level. The stumpage price of timber is expected to rise dramatically, however.

The local situation is similar to that of the regional, with a few exceptions. Wilderness demand is not expected to exceed supply in the near future on the Wenatchee. Over one-half million acres of currently unroaded land exists outside of formally designated wilderness.

Demand for cattle grazing cannot be met in the future under some alternatives. Supply of sheep grazing exceeds demand in all cases. Much of the excess sheep range is not suitable for cattle grazing. The range potential of the Forest cannot be fully realized unless there is an increased emphasis on sheep production by local ranchers

2. ECONOMIC VALUES AND RESPONSES TO MAJOR ISSUES, CONCERNS, AND RESOURCE USE AND DEVELOPMENT OPPORTUNITIES

The major reason that alternatives differ is that each responds in different ways to the issues, concerns, and resource use and development opportunities (ICO's) identified for this Forest. This section summarizes many of these differences in responses by defining indicators of those responses that can be quantified. It also discusses indicators of central concern to the nation as a whole, as owner of this Forest. Appendix A fully discusses each of the ICO's. A less quantified comparison of the responsiveness of the alternatives is found earlier in this chapter in Table II-1. The ICO's and indicators of responsiveness found in Table II-7 include:

- Recreation opportunities and use conflicts

Indicator:

-percent of Forest by recreation opportunity spectrum (ROS) class

- Management of areas that are presently undeveloped

Indicator:

-allocation of inventoried roadless areas to roaded versus unroaded management

- Water quality and quantity

Indicators:

-first decade increased water yield
-average annual sedimentation over the planning horizon

- Wildlife and fish

Indicators:

-acres allocated to Key Big Game Habitat Management Area
-acres of old-growth retained (fifth decade)
-commercial harvest of anadromous fish

- Management of scenery

Indicator:

-percent of Forest by visual quality objective (VQO).

- Timber Management

Indicators:

-first decade average annual harvest (allowable sale quantity plus unregulated volume)
-long-term sustained-yield capacity
- acres of suitable timber lands

- Minerals

Indicators:

-lands that are withdrawn and relatively unrestricted by management prescriptions in terms of total forest area.

- Social/Economic

Indicators:

-first decade payments to counties
-first decade change in employment
-first decade change in income

In addition, the nation as a whole has an interest in ensuring that the Forest is managed in a financially prudent manner while the quality of the physical environment is protected and enhanced. Indicators of national interest include:

- Present net value
- First and fifth decade net receipts (cash flows)
- First and fifth decade noncash benefits

1/ Alternatives are ranked in order of decreasing present net value (except for NC which does not have a PNV computed) All resource outputs cannot be reasonably estimated for Alternative NC because the TM plans were based on different yield tables and resource relationships.

2/ Alternative J has different standards and guidelines for key wildlife habitat areas and Retention/Partial Retention areas than the other alternatives. Refer to Appendix D for more information

3. DIFFERENCES AND SIMILARITIES OF INDIVIDUAL ALTERNATIVES

The alternatives are ranked in order of decreasing present net value (PNV) in Table II-7. They are discussed below in the same order.

a. ALTERNATIVE A/NFMA

Alternative A/NFMA is the No-Action Alternative. It is implementable as it now provides for the management requirements mandated by the National Forest Management Act of 1976 (NFMA).

Alternative A/NFMA has the highest present net value of the alternatives. One major contributor to the high PNV for this alternative is the low recreation budget, while recreation benefits remain high. Alternative A/NFMA has the highest net receipts (though still negative) of all the alternatives for the first decade. By the fifth decade, Alternative A/NFMA slips to third in net receipts because the intensive timber management practices in Alternatives B and J increase receipts over Alternative A/NFMA. It has non-cash benefits at a level slightly higher than the other alternatives.

Alternatives A/NFMA and H allocate the fewest acres of the inventoried roadless areas to un-roaded management with the exception of Alternatives B, D, J, and the No-Change Alternative. Of those areas remaining roadless, a greater proportion is assigned to motorized use than most alternatives. By the end of the second decade, only Alternatives G and H have a greater percentage in the Semi-Primitive Motorized Recreation Opportunity Spectrum class.

With the exception of Alternative NC, alternative A/NFMA has the fourth lowest level of water yield and the fifth lowest level of sedimentation. Both factors are closely correlated to timber harvest levels, although they are also influenced by the location and type of harvest. The sedimentation level is higher than would be expected based on harvest level alone.

Alternatives A/NFMA and H have the fewest acres allocated to management for key big game species than other alternatives. Alternative A/

NFMA, by the fifth decade, has greater amounts of old-growth remaining than any other alternatives, except for Alternatives E and F. Anadromous fish production is the same for all alternatives in the first decade.

Alternatives A/NFMA and H result in 17.5 percent of the Forest ending in a modified visual environment over the 50-year planning horizon. This is near the middle of the range of alternatives as five alternatives modify the visual environment more with three alternatives modifying it less. The modification of the visual environment is directly proportional to the volume of timber harvest and its rate.

Alternative A/NFMA has the eighth highest timber harvest in the first decade with the sixth highest long-term sustained yield. It has the sixth highest acreage of suitable timberlands. The objective function in FORPLAN is to maximize present net value.

Alternatives A/NFMA and NC are fourth highest in acres open to mineral resources with only moderate to few constraints.

Alternative A/NFMA has the eighth highest level of jobs and income change from the 1982 base period. The change in jobs and income is directly related to the timber harvest level. The higher the timber harvest, the greater the gain in jobs and local income. Alternative A/NFMA has the sixth highest level of payments to counties. The payment to counties is somewhat related to the level of timber harvest. In general, there is a direct correlation, but for Alternatives B and J the payment to counties level is lower because these alternatives harvest less valuable timber in the early decades. For the later decades, the payment to counties increases for these alternatives.

b. ALTERNATIVE D

Alternative D has the second highest present net value of the alternatives. This is due to the high acreage allocated to some sort of timber management coupled with the use of the maximize present net value objective function in FORPLAN. Alternative D has the second highest net receipts of all the alternatives for the first decade. By the fifth decade, Alternative D is fourth in net receipts.

Alternatives D and B have the third lowest allocation of the inventoried roadless areas to unroaded management. Only Alternatives J and NC have less roadless areas allocated to unroaded management.

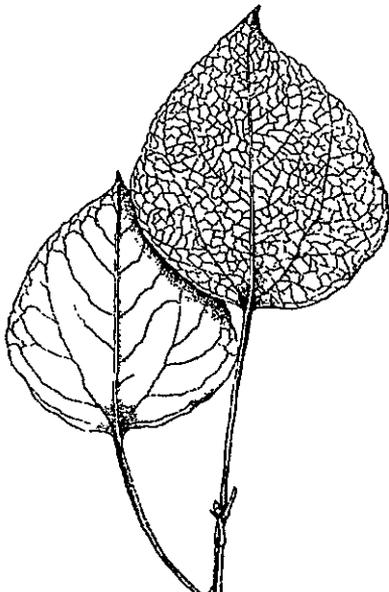

Alternative D has the sixth highest level of increased water yield and eighth highest level of sedimentation of the alternatives. This is closely correlated with timber harvest level. Alternative D also has the sixth highest level of timber harvest.

Alternatives D and B have the third fewest acres allocated to key big game species. By the fifth decade Alternative D has the fourth fewest acres of old-growth remaining. Anadromous fish production is the same as other alternatives.

Alternatives D and B result in 32.6 percent of the Forest ending in a modified visual environment over the 50-year planning horizon. Only Alternatives J and NC end up with a more modified visual environment. Alternative D has the sixth highest timber harvest, but the third highest long-term sustained yield. It has the fourth highest suitable timberland base.

Alternatives D and B are second highest in acres open to mineral resources with only moderate to few constraints.

Alternative D has the sixth highest level of jobs and local income of the alternatives and the third highest level of payment to counties.

c. ALTERNATIVE C - Preferred

Alternative C has the third highest present net value of any alternative. Alternative A, which has the highest present net value, is 3.5 percent higher. Alternative C was constrained in FORPLAN to produce an allowable sale quantity of 136 MMBF. This resulted in a reduction of about one percent from the maximum PNV level for this alternative. Alternative C, however, maximizes net public benefits and was, therefore, selected as the preferred alternative.

For the first decade, Alternative C has the fifth highest level of net receipts. By the fifth decade, this ranking would likely slip to sixth highest level of net receipts. It has non-cash benefits at a slightly higher level than most of the other alternatives, but the difference is not significant.

Alternatives C and I allocate the fourth highest acreage of the inventoried roadless areas to roadless management. Alternative I, which is the departure alternative, has the same land allocations. Only Alternatives E, F, and G have greater allocations to unroaded management. Roadless areas allocated to roaded management would be developed faster under Alternative I than under Alternative C.

Alternative C has the seventh highest water yield and the fifth highest rate of sedimentation.

Alternatives C and I have the fifth highest acreage allocated to key big-game species. At the end of the fifth decade, Alternatives C and I will have the third highest level of old-growth remaining. At this point, there should be 261,200 acres of old growth remaining. Anadromous fish production is the same as other alternatives.

Under Alternatives C and I, 21.5 percent of the forest ends up in a modified visual environment over the 50-year planning horizon. In the range of alternatives, this is the fifth highest.

To maximize net public benefits, the allowable sale quantity for Alternative C was set at 136 MMBF. This is the seventh highest timber harvest level. It also has the seventh highest long-term sustain yield level and suitable timberland base.

Alternatives C and I have 38.8 percent of the land base open to mineral resources with only moderate to few constraints.

Alternative C has the seventh highest level of job increase and income. This alternative has the fourth highest level of payment to counties.

d. ALTERNATIVE F

Alternative F has the fourth highest present net value. It has a large portion of the inventoried roadless areas allocated to roadless management. This reduces the level of timber harvest, which reduces PNV. Most of the benefits of not roading these areas are unquantified and must be subjectively weighed to determine the net public benefits of the alternative.

Alternative F has the fourth highest net receipts in the first decade, dropping to the sixth highest net receipts by the end of the fifth decade. The non-cash benefits to users are slightly lower than the other alternatives, but the differences are not significant.

Alternative F allocates the second highest acres of the inventoried roadless areas to unroaded management. Only Alternative E has a greater allocation to unroaded management.

Alternative F has the next to lowest water yield of any alternative. It also has the next to lowest amount of sedimentation. Both factors are closely correlated to timber harvest levels.

Alternatives F and E have the highest acre allocation to management for key big-game species with. Alternative F maintains the second highest level of old-growth, only slightly lower than Alternative E. Anadromous fish production is the same as other alternatives.

Alternative F would have the second most natural appearing landscape of the alternatives. Only Alternative E would have a more natural appearing landscape.

Alternative F has the next to lowest level of timber production both in the first decade and long-term. It has the second fewest acres of suitable timberlands.

Alternative F has the second fewest acres available for relatively unconstrained mineral related activities.

Alternative F has the next to lowest level of jobs and income of the alternatives. The job change is -473 jobs and the income change is -13.3 million dollars. The payment to counties level is the ninth highest at 2.0 million dollars.

e. ALTERNATIVE G

Alternative G has the fifth highest present net value. It has the sixth highest net receipts for the first decade; by the fifth decade the net receipts drop to the seventh highest. The non-cash benefits are slightly higher than the other alternatives for the first decade. By the fifth decade, this alternative drops to second highest in non-cash benefits. However, the differences are not significantly different between the various alternatives.

Alternative G has the third highest allocation of inventoried roadless areas to unroaded management. Only Alternatives E and F have more roadless areas allocated to roadless management. This alternative has the greatest amount of roadless area available for the trail bike use.

Alternative G has the ninth highest water yield sediment produced. These correspond fairly closely to the level of timber harvest.

Alternative G has the third highest allocation to key big-game species. It is only a couple of thousand acres below the maximum for Alternatives E and F. The old-growth acreage at the end of the fifth decade is the eighth highest of the alternatives. Anadromous fish production is the same as other alternatives.

Alternative G results in 14.5 percent of the Forest ending in a modified visual environment over the 50-year planning horizon. Only Alternatives E and F have less acreage in a modified visual environment. This is because the modification of the visual environment is directly proportional to the volume of timber harvest and its rate.

Alternative G has the third lowest level of timber harvest and long-term sustain yield level. The suitable timberland base is also the third lowest of the alternatives.

Alternative G has the third lowest level of land open to mineral development with 36.3 percent of the land with only moderate to few constraints.

Alternative G has a net change of -225 jobs and -6.54 million dollars. The payment to counties level is 2.5 million dollars--the seventh highest level of the alternatives.

f. ALTERNATIVE H

Alternative H has the sixth highest present net value of the alternatives. This alternative has the same allocations as Alternative A/NFMA, except for the Wild and Scenic River recommendations which match Alternative C recommendations with private land removed from the recommended segments. Alternative A/NFMA produces a level of timber harvest that maximizes present net value, while Alternative H produces a level of timber harvest that maximizes first decade timber harvest subject to non-declining flow. Alternative H produces 24 percent more timber than Alternative A/NFMA in an attempt to meet historic levels of timber harvest. This results in a decrease in total present net value of 5.5 percent.

Alternative H has the fifth lowest net receipts for the first decade, dropping to the third lowest net receipts by the fifth decade. The level of non-cash benefits to users is similar to the other alternatives.

Only Alternatives NC, B, D and J have fewer acres of inventoried roadless area allocated to unroaded management. Alternative A has the same roadless allocation as Alternative H; the roadless areas, however, would be entered at a faster rate in Alternative H.

Alternative H would have the fourth highest increased water yield and sedimentation. Alternatives NC, B and J are the alternatives that would be higher.

Alternative H has the second fewest acres allocated to key big-game species of the alternatives. At the end of five decades, Alternative H does have the sixth highest level of old-growth remaining. Anadromous fish production is the same for all alternatives in the first decade.

Alternative H results in 17.5 percent of the Forest ending in a modified visual environment over the 50-year planning horizon. This is in the middle of the range of alternatives. The modification of the visual environment is directly proportional to the volume of timber harvest and its rate. For this reason, modification of the visual environment would occur at a faster rate under Alternative H than Alternative A/NFMA.

Alternative H has the fifth highest harvest level in the first decade, and the fifth highest long-term sustain yield level. It also has the fifth highest acreage of suitable timberlands. The objective function in FORPLAN is to maximize first decade timber harvest subject to non-declining flow.

Alternative H is the sixth highest in acres open to mineral resources with only moderate to few constraints.

Alternative H has the fifth highest level of job increase, the sixth highest level of income increase, as well as the fifth highest level of payments to counties.

g. ALTERNATIVE I

Alternative I ranks seventh in present net value. This alternative has the same allocations as Alternative C. This is a departure alternative where higher timber harvest occur during the first two decades. The harvest level then starts declining in the third decade. For the first decade, Alternative I has the eighth highest net receipts, declining to the lowest net receipts by the end of the fifth decade. This is the result of having higher harvest levels for the first two decades. Alternative I has the same roadless allocations as Alternative C. This is the fourth largest level for the alternatives with 53.6 percent of the inventoried roadless areas remaining roadless. Only Alternatives E, F, and G have greater allocations to unroaded management. Rooding of the

roadless areas proceeds faster in Alternative I than in most of the other alternatives because of the higher levels of timber harvest in the first two decades.

Alternative I has the fifth highest water yield and the sixth highest sedimentation rate.

Only Alternatives E, F, G and J have greater allocations for management of key big-game species. Alternative I maintains the fourth highest level of old-growth at the end of the fifth decade. The level of anadromous fish production is the same as the other alternatives.

Under Alternative I, 21.5 percent of the Forest ends up in a modified visual environment over the 50-year planning horizon. In the range of alternatives this is the fifth highest.

Alternative I has the fourth highest harvest level of the Alternatives. The long-term sustained yield is only the eighth highest of the alternatives. This alternative has the seventh highest suitable timberland base.

The allowable sale quantity for Alternative I is a departure from the base sale schedule established for Alternative C. It equals the average timber volume sold between Fiscal Year 1975 and Fiscal Year 1984 gradually declining to the same level as Alternative C.

Alternative I has 38.8 percent of the land base open to mineral resources with only moderate to few constraints.

Alternative I has the third highest job and fourth highest income change from the 1982 base period. This alternative had the second highest payment to counties level of the alternatives.

h. ALTERNATIVE E

Alternative E has the third lowest present net value of the alternatives. It has the greatest allocation of unroaded management and the lowest level of timber production. This results in a greater proportion of its benefits being subjective contributions to net public benefits rather than being quantified as part of present net value.

Alternative E has the third lowest net receipts in the first decade dropping to the next to the lowest net receipts in the fifth decade. The non-cash benefits to users are comparable to the other alternatives in the first decade and slightly higher than the other alternatives in the fifth decade. The differences, however, are not significant.

All the inventoried roadless areas outside the Alpine Lakes Management Area are allocated to unroaded management (90 percent Forest-wide). This is the most of any alternative.

Alternative E has the least amount of increase in water yield of the alternatives. It also has the least amount of sedimentation and the highest water quality.

Alternatives E and F have the highest acre allocation to management for key big game species. Alternative E maintains the highest level of old-growth of all the alternatives. Anadromous fish production is the same as other alternatives

Alternative E would have the most natural appearing landscape of any alternative. Only 11.4 percent of the Forest would be managed under the visual quality objective of modification or maximum modification.

Alternative E has the lowest level of timber harvest both in the first decade and the lowest long-term sustained yield level. It has the fewest acres of suitable timberlands.

Alternative E has the fewest acres available for mineral-related activities. For the alternative, 30.8 percent of the land is open to mineral activities with only moderate to few constraints

Alternative E shows the lowest level of jobs and income of all the alternatives. This alternative shows a change of -520 jobs and -14.56 million dollars. Alternative E also has the lowest payment to counties level at 1.9 million dollars.

i. ALTERNATIVE J

Alternative J has the next to the lowest present net value of all the alternatives. This is a result of heavy timber investments in the early decades which significantly reduced present net value for this alternative. Alternative J has the next to the lowest net receipts for the first decade. By the fifth decade, however, the early timber investments raise the net receipts to the second highest.

Alternative J allocates the second fewest acres of the inventoried roadless areas to roadless management. Of the inventoried roadless areas, 37.6 percent would remain roadless under this alternative.

Alternative J has the highest increased water yield and the highest sedimentation rate of the alternatives. This is closely correlated with timber harvest level. Alternative J has the highest timber harvest level of the alternatives.

Alternative J has the fourth highest allocation to key big-game species. The prescription for key big-game species is slightly different than the other alternatives in its treatment of thermal cover. The yield tables used in Alternative J are the same as that for general forest prescription, but it has road closures and other management activities to protect and enhance key big-game species habitat. By the fifth decade, Alternative J has the lowest acreage of old-growth remaining. Anadromous fish production is the same as other alternatives.

Alternative J results in 34.0 percent of the Forest ending in a modified visual environment over the 50-year planning horizon. This is the second highest level of the alternatives. It uses different standards and guidelines for visual treatment along roads and visual corridors. These guides do not correspond to the ST-1 or ST-2 prescriptions. See Appendix D.

Alternative J has the highest first decade harvest level, the highest long-term sustained yield, and the second highest acreage in suitable timberlands.

Alternative J has the largest amount of acreage open to mineral resources with only moderate to few constraints.

Alternative J has the highest gain in jobs and income of the alternatives. This is because this alternative has the highest timber harvest level. Alternative J has the eighth highest level of payment to counties.

j. ALTERNATIVE B

Alternative B has the lowest level of present net value of any alternative. It has the same land allocations as Alternative D, which has the second highest PNV of the alternatives. Alternative D produced the quantity of timber which achieved the highest level of PNV, subject to meeting other resource considerations. Alternative B produces 31 percent more timber than Alternative D, while still meeting other resource constraints. The costs of producing the additional timber exceed the benefits. This results in a PNV nine percent below the level of Alternative D.

Alternative B has the lowest net receipts in the first decade due to the high level of timber investments in the early decades. However, this investment results in Alternative B having the highest net receipts of all alternatives by the fifth decade.

Alternative B has the third lowest acres of inventoried roadless area allocated to unroaded management. Rooding of the areas allocated to rooded management would occur the fastest in this alternative and Alternative J.

Alternative B has the second highest level of increase water yield and third highest level of sedimentation of any alternative. This is a result of the level of timber harvest.

Alternative B has the seventh highest level of acreage allocated to management for key big-game species. Alternative B will have the second lowest level of old growth remaining by the fifth decade. Anadromous fish production is the same as for the other alternatives.

Alternative B would have the third least natural appearing landscape by the fifth decade. At that time, 32.6 percent of the landscape will appear modified. Alternative B would alter the landscape at the second fastest rate.

Alternative B harvests the second highest level of timber of the alternatives. It also has the second highest long-term sustained yield capacity and the third highest acres of suitable timberland. In Alternative D, which has a maximize present net value objective function and the same land allocations as Alternative B, not all the timber is harvested on land available for timber harvest. Some acres are not utilized because they are not economically efficient. Alternative B, however, harvests timber on lands that were not utilized in Alternative D. Alternative B also utilizes more intensive management with more precommercial and commercial thinning.

Alternative B has 43.3 percent of the land area open to mineral activities with only moderate to few constraints.

Alternative B is second to Alternative J in change of jobs and income increasing by 577 jobs and 15.31 million dollars. This alternative has the third lowest payment to counties level at 2.0 million dollars.

k. NO CHANGE (NC)

The No Change Alternative does not have a PNV computed. A comparison of resource outputs is not made for Alternative NC because the Timber Management plans were based on different yield tables and resource relationships.

CHAPTER III

AFFECTED ENVIRONMENT

A. INTRODUCTION

This chapter describes the area that will be affected by the proposed plan or the alternatives to it. In Section B of this chapter, each significant environmental component ^{1/} or land use is described in terms of (1) current conditions, (2) historic trends, (3) anticipated conditions and use levels, and (4) the role of the environmental component, or land use in the ecological systems of the Forest and affected area, and in the social and economic structure of the areas affected by the Forest.

^{1/} The term "environmental component" is used to identify those significant components which make up the physical, biological, and social environment of the Forest. These terms are used to direct our discussions toward the actual environment with less emphasis on the Forest Service programs. Use of these terms strengthens the ties between this chapter and Chapter IV, Environmental Consequences.

The environmental components discussed in the descriptions are arranged in the following order:

Recreation Setting
Roadless Areas
Wild, Scenic and Recreational Rivers
Cultural Resources
Scenery
Wilderness
Wildlife
Fisheries
Vegetation: Trees
Vegetation: Old Growth
Vegetation: Forage
Vegetation: Unique Ecosystems
Vegetation: Sensitive Plants
Vegetation: Research Natural Areas
Water
Soils
Air
Minerals
Roads
Fire
Social/Economic

INTRODUCTION

1. LOCATION

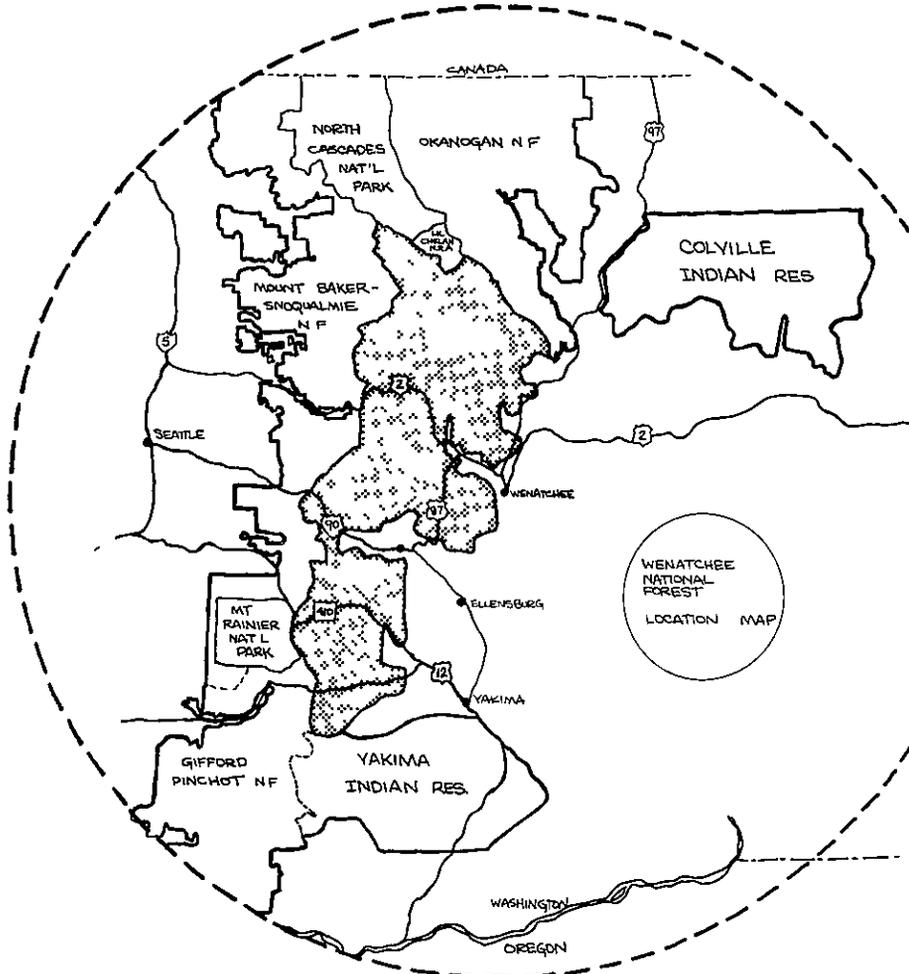

The Wenatchee National Forest is on the east slope of the Cascade Mountains in Central Washington (Figure III-1). The Forest, with a net area of 2,164,180 acres, extends about 140 miles from north to south and from 25 to 55 miles east to west. There are 2,457,379 acres of land within the Forest boundaries of which 293,199 acres are State, private, or other Federal lands.

The Forest is located in Chelan, Kittitas, and Yakima Counties. Badger Mountain lookout site, an isolated two acre tract in Douglas County, is also included in the Forest area. Neighboring National Forests include the Okanogan in the north and the Mt. Baker-Snoqualmie and the Gifford Pinchot National Forests on the west. The Naches Ranger District is within the proclaimed boundaries of the Mount Baker-Snoqualmie National Forest but is administered

by the Wenatchee National Forest. A parcel of Okanogan National Forest near Chelan is also administered by the Wenatchee. An isolated 9,032 acre parcel of the Wenatchee in the Liberty Bell area, in the northern tip of Chelan County, is administered by the Okanogan National Forest. The Forest is bounded by portions of the Lake Chelan National Recreational Area, the North Cascades and Mt. Rainier National Parks, and the Yakima Indian Reservation (Figure III-1).

Major east-west highways on the Forest include U.S. 12 - White Pass, I-90 - Snoqualmie Pass, U.S. 2 - Stevens Pass, and Highway 410 - Chinook Pass (closed in the winter). U.S. Highway 97 is a major north-south route that crosses Blewett Pass and then parallels the east side of the Forest from Wenatchee to Chelan. Much of the Forest is within a two hour drive for the 2 million people who live in the heavily populated Puget Sound region.

**FIGURE III-1
WENATCHEE NATIONAL FOREST LOCATION MAP**

2. LANDFORMS AND GEOLOGY

a. Landforms

The Forest extends into parts of three different landforms as described by Easterbrook and Rahm (1970). Each landform has its own distinct structural architecture. The three landforms are the North Cascades and South Cascades in the Cascade Province and the Yakima Folds in the Columbia River Province. Elevations range from about 800 feet on the eastern edge of the Forest to a little more than 9,500 feet (Bonanza Peak) in the Glacier Peak Wilderness.

North Cascades Landform

The North Cascades landform encompasses all of the Forest north of Snoqualmie Pass, I-90. The higher elevations are characterized by very rough, broken, and jagged features. Most of the valleys have been glaciated, so have been straightened and widened, and have the characteristic "U" shape. There are a few "V" shaped valleys that were formed by faulting and stream down cutting.

South Cascades Landform

All of the Forest south of Snoqualmie Pass and Interstate 90 is in the South Cascades landform, except a few areas along the eastern edge that are in the Yakima Folds Landform. The South Cascades landform is less rugged than the North Cascades and has much less relief. Most of this area was not glaciated, however, there were a few alpine glaciers that came down some of the valleys along the western edge of the Forest.

Yakima Folds Landform

The Yakima Folds landform borders the eastern edge of the Forest south of Wenatchee including Oak Creek and eastern edge of Manastash Ridge. This landform is characterized by Columbia River basalt flows that overrode older landforms. Today these flows form long, broad, gently sloping plateaus that have cliffs and steep talus slopes along the base of the cliffs.

b. Geology

There are more than 30 different geologic formations occurring within the Forest. These can be grouped into six main groups as follows:

(1) granite, gneiss, schist, and diorite; (2) basalt, andesite, and rhyolite; (3) sandstone, shale, conglomerate, and dolomite; (4) flow breccia, tuffs, and volcanic ash and pumice; (5) serpentine; and (6) glacial till, glacial outwash, and alluvium. Geologically the Forest is very complex; changes in rock types often occur within short distances.

3. CLIMATE

The Cascade Mountains and the prevailing westerly winds are the dominant climatic factors on the Forest. The usual situation is that moist maritime air from the Pacific Ocean uplifts and cools as it moves east over the Cascades. Most precipitation occurs in late fall and winter.

The Cascade Crest area is characterized by heavy precipitation (90-140+ inches), low temperatures, heavy snow accumulation (25 feet +), and a short frost free season (95 days at Stevens Pass). As the air masses move east toward the Columbia River Basin, moisture progressively drops off resulting in near desert conditions with less than 10 inches of precipitation, high summer temperatures, very low relative humidity, and a long frost free season (174 days at Wenatchee) on the eastern fringes of the Forest. The wide range in climate creates a related range in forest vegetative types.

Violent summer thunderstorms periodically occur on the Forest, which results in the ignition of forest fires when conditions are right. Such storms may also result in flash floods when accompanied by high intensity rains.

4. LAND OWNERSHIP

a. Overview

About 12 percent, or 293,199 acres, of the land within the Forest boundary is not National Forest land. Many of these lands are in a "checkerboard" ownership pattern, where private individuals or companies own alternate land sections. Most of this checkerboard ownership is in the center of the Forest in the vicinity of Stevens (U.S. 2) and Snoqualmie (I-90) Passes and along the east side of the Forest. Much of the inter-

INTRODUCTION

mingled private land is managed for timber production by large corporate landowners. Almost all of it is within the roaded portion of the Forest and only a minor amount is within wilderness or other unroaded areas. This pattern is evident on the Forest map.

In addition to the large corporate ownerships, the forest has within and adjacent to it many thousands of acres of small private parcels. These ownerships usually originated as homesteads and, until recently, were managed as farms. These private parcels are now being rapidly converted to small, recreation oriented parcels, multiplying the number of private landowner/neighbors within the Forests. These new neighbors have different views than the traditional settler/farmer of how the adjacent National Forest land should be managed.

Other public agencies also manage land within the Forest. The Washington State Department of Natural Resources manages more than 30 square miles of land scattered throughout the northeast part of the Forest (primarily Sections 16 and 36). The Washington State Department of Wildlife manages about 10 square miles of land within affected sections inside Forest boundaries and the Washington State Parks Commission manages Lake Wenatchee State Park which is about one square mile of land.

Other agencies have withdrawal authority for such activities as mineral entry for power sites, reclamation administration, and recreation. The Bonneville Power Administration has several major energy transmission corridors on the forest which are managed under Memorandums of Understanding. The need of other agencies (Federal, State, and local) to occupy and use National Forest land for travel and utility corridors requires considerable management attention and interagency coordination.

To improve resource management and reduce the costs of National Forest administration, the Forest continues to be engaged in several land exchanges with owners of intermingled lands. Occasionally it is in the public interest to purchase private lands. This was the case with the private lands within the Alpine Lakes Intended Wilderness and key recreation lands within the Lake Chelan and Lake Wenatchee recreation areas.

In the last few years, especially on Lake Chelan, emphasis has shifted from purchase to acquiring recreation or scenic easements.

Many rights-of-way have also been acquired through private land. In addition, there is a continuing program for the acquisition of trail and road rights-of-way in order to ensure public access to National Forest lands.

b. Land Adjustments

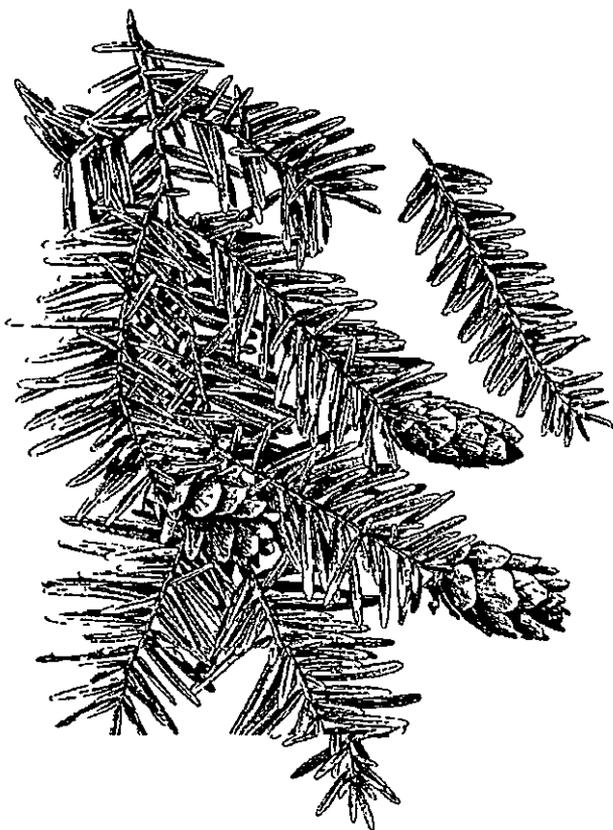

The Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA) targets for land purchase and exchange for the Forest are shown in Appendix B of the Forest Plan. Under current national direction, little or no purchase can occur outside the Congressionally directed Alpine Lakes acquisitions.

Land exchange activities will largely be limited to those under existing agreements with Burlington Northern Timberlands Inc. (Plum Creek Limited Partnerships), the State of Washington Department of Natural Resources (DNR), and Longview Fibre Co. The agreement with the DNR identifies an eventual adjustment involving about 20,000 acres in each ownership. The program with Burlington Northern Timberland Inc. proposes the study of about 83,000 acres of Burlington Northern lands and about 53,000 acres of National Forest land for possible exchange. The Forest is also working on exchanges involving about 17,000 acres of National Forest land for about 23,000 acres owned by Longview Fibre Company. A long-term land ownership adjustment program involving these three major landowners could potentially involve about 120,000 acres of private land and a similar acreage of National Forest land. Other small parcels would be acquired by exchange or purchase on a need and opportunity basis.

In "checkerboard" ownership areas, industrial forest management practices result in much faster harvest of old-growth timber on private land. This rate of cutting and the related road building substantially affects road building and timber harvest on public lands because of the cumulative effects of these activities on soil and water quality. These intermingled areas also limit the opportunity to manage the public lands for unroaded uses.

The subdivision and development of private lands within and adjacent to the Forest is accelerating. Current examples are: (1) The Murray Pacific lands in Chelan County above Fish Lake and in the Chiwaukum, Hatchery and Icicle Creek areas; and (2) the Pack River Management Co. lands in the bottom of the Icicle Creek drainage. Such changes impact public land management in several ways. These include fire protection, access, sanitation (water quality), and trespass. Private land development also increases the recreation use of the Forest in these areas increasing the demand for the use of National Forest lands including water systems, sanitation systems, utilities, and access. There are also demands to preserve the natural environment in proximity to summer homes or residences. This development creates pressure to restrict management options on activities such as timber harvesting and road, trail, and campground construction.

In order to allow maximum utilization and adequate protection of public resources, the ownership pattern requires either: (1) a large, long-term landline survey program; (2) large scale land ownership adjustments to eliminate the mixed ownership; or (3) a combination of the two.

5. LAND USES BY OTHERS

a. Special Land Uses and Utility Corridors

The Forest provides lands for a wide variety of uses by private individuals and public agencies. Such uses are authorized by special use permits, mining laws, and withdrawal authority of other agencies. The most common are those covered by special use permits. Examples of permitted uses are recreation residences, pastures, power or telephone lines, fences, irrigation ditches, water transmission pipelines, roads, dams, emergency airstrips, electronic sites, ski areas, and resorts.

There are about 1,700 special uses on the Forest. Six hundred ninety of these special permits, occupying 2,855 acres, are for recreational purposes. Another 1,010 occupy about 25,000 acres of National Forest land, and are termed non-recreational special uses. Special uses produced \$236,084 in fees in fiscal year 1984. The number of permits and acres under permit change as some permits terminate and new uses are added. However, the trend is for more and more uses as time goes on. The uses have the effect of limiting the options in these areas for other uses including public recreation, timber harvest, domestic livestock grazing, and facility construction.

Special uses are periodically inspected to insure compliance with conditions of the permit and to evaluate the appropriateness of continuing such use. Most permittees are charged fees for the privilege of using National Forest lands.

Utility corridors are managed under Cooperative Agreements and Memorandums of Understanding. The Forest maintains about 200 of these documents to administer various uses. Currently, power transmission lines are the major use of utility corridors on the Forest with three major energy utility corridors crossing the Forest through Stevens, Snoqualmie, and Stampede Passes. The rights-of-way for these lines are from 100 feet to 1,400 feet in width and they occupy about 1,420 acres of National Forest land. The Western Regional Corridor Study for the State of Washington has also identified one additional potential corridor. It would cross the crest of the Cascade Range in the area between Tacoma Pass and Pyramid Pass. The corridor would then run

INTRODUCTION

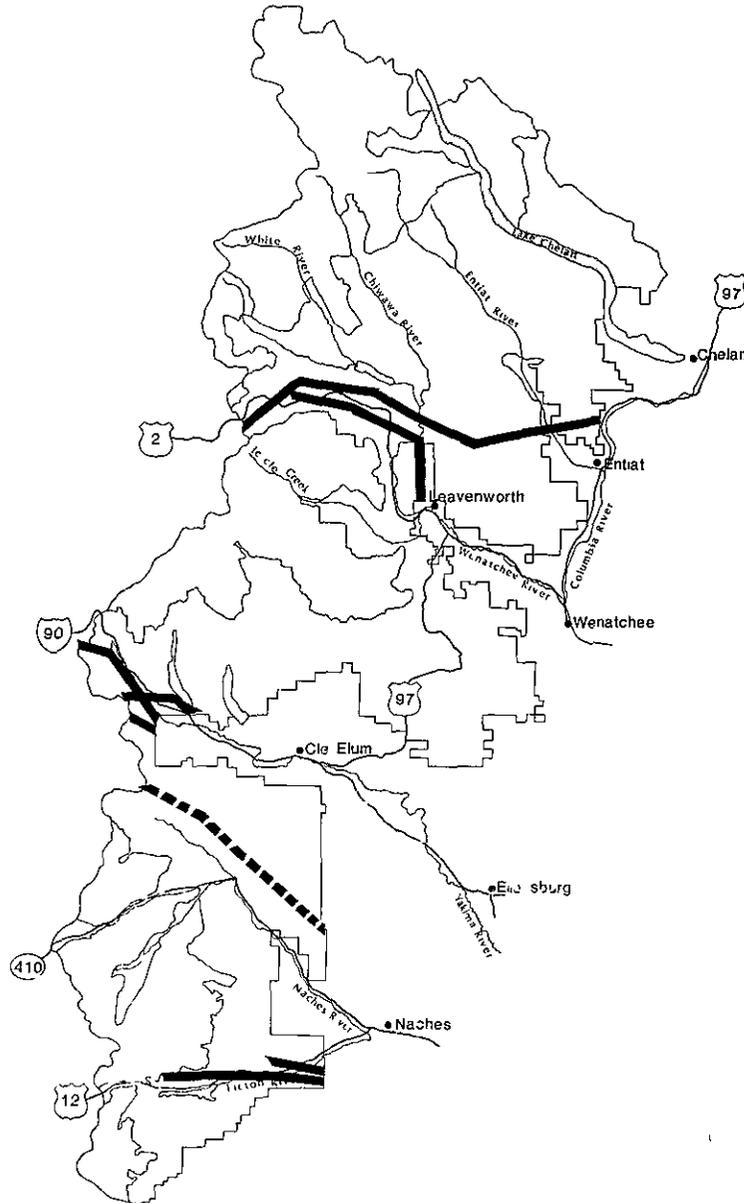

southeasterly toward the Hanford and Tri-Cities area. In the short term, additional power transmission needs can be met by increasing the capabilities of existing utility corridors.

A moderate to strong demand can be expected for all special uses in the future. This is based on the number of applications currently received for non-recreation special uses. The right-of-way acquisition, grants of right-of-way, and road construction cost sharing are expected to continue at about the current level. As the road system develops over time, these programs should be phased out, except for cost sharing of road reconstruction

and maintenance. The need for these activities will also be reduced to the extent that land exchanges with the major landowners within the Forest will consolidate ownerships, eliminating the need for cost sharing, granting and acquiring right-of-way, and surveying and marking property boundaries.

The effects of the Forest ownership pattern on the recreation, fish, wildlife, cultural, and timber resources are further discussed in this chapter in sections dealing with those resources.

**FIGURE III-2
UTILITY CORRIDORS**

b. Hydroelectric Energy Development

There are no major hydroelectric power projects within the Forest. There are several projects adjacent to the Forest on the Columbia River. One project, Chelan Falls, relies on water storage in Lake Chelan. Generation of electric power results in a 17 foot annual fluctuation in the level of Lake Chelan, and affects National Forest land management adjacent to the shoreline.

There are two minor projects of long standing on the Forest. One is the Holden project on Copper Creek at Holden Village. The other is the Trinity project on Phelps Creek on the Lake Wenatchee Ranger District. Both of these projects have existed for more than 30 years and serve small, isolated camp/organization sites.

Over the last five years, the Forest has had an average of about 25 small hydroelectric proposals pending. Most of these never go beyond the preliminary permit and feasibility study stage. Many are "repeats", where one proponent surrenders a preliminary permit for a proposal and another party applies for a preliminary permit for the same site.

Three proposals have reached the stage of applying for licenses to construct and operate small hydroelectric projects. They are the Tieton, Clear Lake, and Railroad Creek projects. The Tieton and Clear Lake proposals involve "retrofitting" existing irrigation storage dams to produce power. The Railroad Creek proposal would have been a totally new project to provide power for the Holden Village organization site. However, after reaching the license application stage, Holden Village withdrew its application.

Under federal hydroelectric licensing procedures, the Forest Service prepares a report, [called a "4(e) report"] on each hydroelectric project proposed on National Forest system lands. The report is done after the feasibility study has been completed and when an application for a license to construct and operate a hydroelectric project has been filed with the Federal Energy Regulatory Commission (FERC). In the 4(e) report, the Forest Service identifies the project's impacts on the National Forest system lands and resources involved in the project. Also, in the report the

Forest Service identifies the terms and conditions needed to avoid, minimize and/or mitigate the effects of these impacts. The FERC then incorporates the terms & conditions from the 4(e) report in the license for the project.

6. LAW ENFORCEMENT AND PUBLIC SAFETY

The major responsibility of law enforcement is to ensure the safety and peace of National Forest System visitors and to protect natural resources and Federal property. The protection of Forest users is generally accomplished through cooperative agreements with the respective County Sheriff's Departments to provide law enforcement service.

Search and rescue is primarily the responsibility of the Sheriff's Department for Chelan, Kittitas, and Yakima Counties. Forest Service personnel may either supervise initial search and rescue operations until the Sheriff's Department personnel take control, or may assist as provided for under cooperative agreements. As the amount of public use of the public lands under National Forest administration increases, we have experienced and will continue to experience a corresponding increase in search and rescue activities. This will intensify the on-going coordination between the Forest and the appropriate Sheriff's Department.

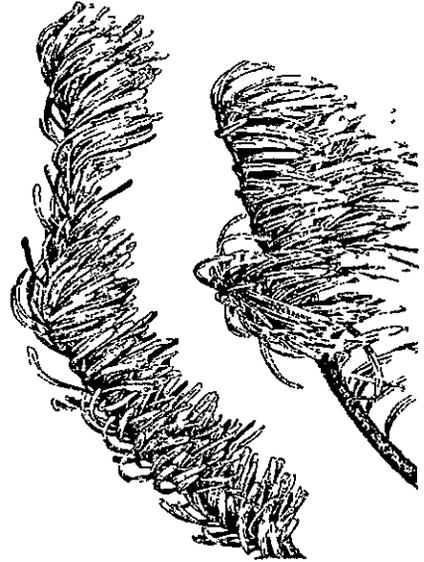

Crimes occurring within the National Forest, such as thefts of personal property, assaults, homicides, drug usage, and marijuana cultivation, are primarily the responsibility of the Sheriff's Department and are typically covered by the cooperative agreements. As the amount of public use of National Forest increases, there are corresponding increases in criminal activity.

It is more difficult to predict the increase in criminal activity which results in the theft or destruction of natural resources. Theft of natural resources appears to be influenced by many socio-economic factors. Market prices, demand for resources, access to the natural resource (sawlogs, firewood, Christmas trees, minerals, etc.), and the general condition of the economy all appear to be related to the incidence of natural resources theft.

INTRODUCTION

Without management action, destruction of natural resources and Federal property can be expected to increase with the increased use of the Forest. Proper planning and management is necessary to minimize the adverse effects of increased use on the safety of Forest users and to insure protection of natural resources from theft, vandalism, and fire.

Forest users themselves are important contributors to effective law enforcement as they exert peer pressure on other users, extinguish abandoned campfires, gather litter, and report suspicious activity to Forest authorities.

B. DESCRIPTION OF THE ENVIRONMENTAL COMPONENTS

1. RECREATION SETTING

a. Overview

A tremendous diversity of elevation, vegetation, and precipitation on the Wenatchee National Forest results in an equal variety of recreation uses and opportunities. The Forest has been the sixth most heavily visited National Forest in the country for the past several years, and the diversity of uses is unsurpassed.

The Forest stretches 140 miles from north to south and is 25 to 55 miles wide. It lies entirely east of the crest of the rugged Cascade Range in typically sunny eastern Washington. It rises in elevation from the breaks of the Columbia River in the Columbia Basin through open stands of ponderosa pine and bitterbrush to broad forested plateaus like Table Mountain southwest of Wenatchee. From there it rises through dense forests of pine and Douglas-fir to sub-alpine stands of spruce and fir. Next it reaches into the alpine areas with lofty gardens of hardy conifers sculptured by the elements, lush flowered meadows, and sparkling lakes and tarns. Finally, the Forest leaps to the tips of the peaks themselves--towering granite spires more than 9,500 feet tall, which are draped in ice and snow for much of the year.

Vast acreages of open, accessible forest, plus thousands of miles of winding forest roads and trails, are an invitation to recreation use. Since most of the Forest is within a two hour drive of the Puget Sound metropolitan area, tens of thousands of vehicles bearing recreation visitors stream through the mountain passes on typical summer weekends. Thousands of additional users come from the communities of eastern Washington to the cool, green forest retreats in the mountains.

Recreation is heaviest in the summer months, but occurs in all seasons of the year. In the early spring, hikers, horse users, and trailbike enthusiasts flock to low elevation trails. These activities follow the melting snows upward during the summer until fall storms begin to push users back down into the valleys. Scenic highways and forest roads are equally attractive to visitors, and driving for pleasure is one of the most popular public recreation uses of the Forest. There are 121 campgrounds and picnic areas offering visitors a rustic camping experience for a few hours or for several days, typically accented by the sound of a breeze in tall conifers and the splashing of a nearby stream.

Indeed, water is one of the focal points for recreation of the forest. Dozens of rivers and creeks begin in melting snows and glaciers and course down through forested valleys to the Columbia River beyond. Hundreds of lakes in shades of green and blue dot the alpine highcountry, and seven very large lakes and reservoirs offer recreation opportunities in mid and lower elevations of the Forest. Water oriented recreation includes fishing, swimming, boating, river rafting, and even gold panning.

The Forest is famed for its colorful variety of wildflowers throughout the spring and summer. Its varied vegetation and topography also is home to hundreds of species of fish, animals, and birds, so viewing wildlife is a common and rewarding recreational activity. The Forest also offers a smorgasbord of huckleberries, blackberries, wild strawberries, and mushrooms at various times during the spring, summer, and fall which attracts dedicated legions of pickers.

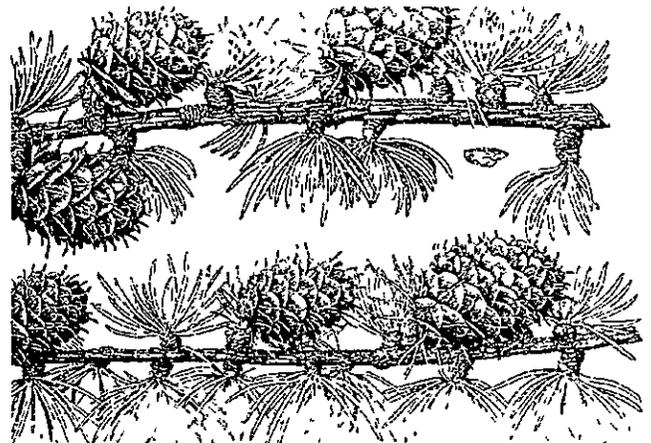

The varied geology of the Forest provides opportunities for rockhounds, who comb the hills in search of agate, geodes, garnets, and soapstone. The Red Top Mountain area north of Ellensburg is a popular gathering spot for rockhounds from throughout the State.

In the fall, Forest visitors are treated to splashes of autumn color from the golden hues of larch, aspen, cottonwood, and big leaf maple and the brilliant reds of vine maple and huckleberry brush. The foliage is picked by visitors for bouquets and serves as the centerpiece for the popular Autumn Leaf Festival at the Bavarian-theme community of Leavenworth.

Another popular activity in spring and autumn is woodcutting. More than 10,000 people purchase woodcutting permits each year, and the roared portion of the Forest echoes with the determined buzz of chainsaws at the peak of the cutting season in the fall. Timber sales in accessible areas are specially designed to make cull logs and slash available to citizen woodcutters.

Fall is also hunting season on the Forest, beginning with seasons on grouse and deer, and ending with elk seasons in late fall and early winter. Since some of the state's largest herds of deer and elk are found within the Forest, thousands of hunters take to the woods each fall. Hunting camps in the Table Mountain and Naches-Tieton areas resemble small communities during elk season.

As snow falls, visitors come to the Forest for winter recreation. Downhill skiing was once the major focus of winter use, and continues to increase steadily in popularity at seven ski areas. Snowmobiling use soared in the 1960's and leveled off in popularity in the late 1970's. However, snowbound forest roads, groomed snowmobile trails, and miles of open rolling terrain continue to attract hundreds of snowmobilers on winter weekends. Cross-country skiing has exploded in popularity in recent years, and outdoor sports shops have done a brisk business in "skinny" ski sales. Skiers also take advantage of snow-covered forest roads as well as several ski trails developed through scenic forest terrain with volunteer labor. Snowmobilers take full advantage of parking provided by state snowplowing at 24 "Sno-Park" sites scattered throughout the Forest.

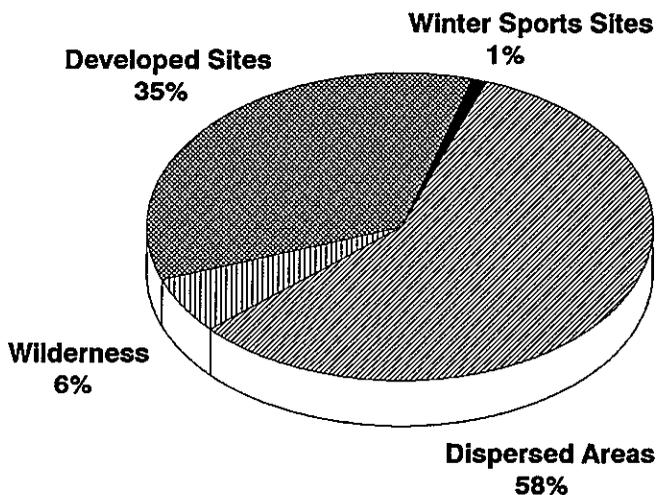

RECREATION SETTING

Because of its size, diversity, and accessibility, the Wenatchee National Forest has a remarkable capacity to absorb recreation use any time of the year. Although recreation use is projected to increase steadily in the future, the Forest has so much to offer that crowding and shortages are expected to be only localized problems.

The Wenatchee National Forest, with almost five million (4,990,000) recreation visitor days (RVD's) of use in 1986, is one of the ten National Forests highest in recreation use. The use is distributed as follows:

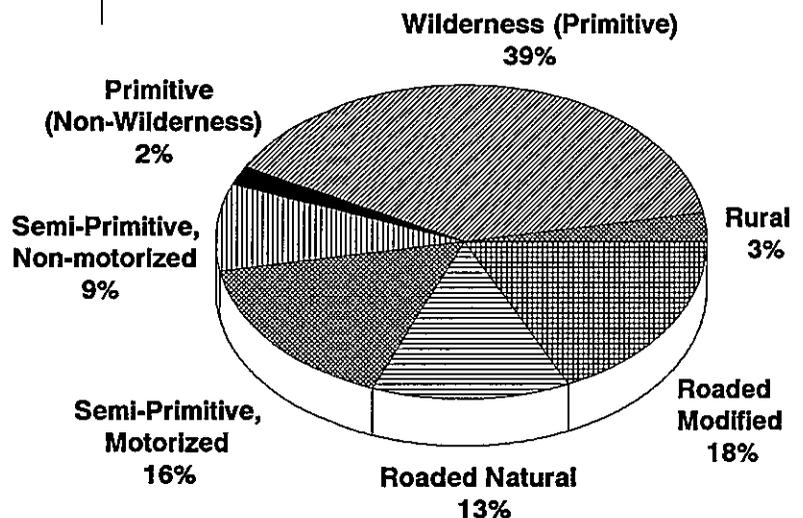

**FIGURE III-3
DISTRIBUTION OF RECREATION USE**

The climatic, topographic, and biologic variety of the Forest, coupled with its road and trail network, lakes, reservoirs, streams and developed facilities, provides a wide array of recreation opportunities. For management and conceptual convenience, possible mixes or combinations of activities, settings and probable experience opportunities have been arranged along a spectrum, or continuum. This continuum is called the Recreation Opportunity Spectrum (ROS) and is divided into six classes ranging from primitive to urban.

The Forest currently has the following distribution of Recreation Opportunity Spectrum classes expressed in percent of net National Forest acres:

**FIGURE III-4
DISTRIBUTION OF RECREATION
OPPORTUNITY SPECTRUM CLASSES**

b. DEVELOPED RECREATION

The Forest provides a full spectrum of developed recreation opportunities. Table III-1 indicates the kind and number of developed sites now in existence.

**TABLE III-1
KINDS AND NUMBERS OF
RECREATION SITES**

Kind of Site	Number of Each
Observation	3
Boating	7
Trailhead	12
Campground, Family	115
Campground, Organized Group	3
Picnic Ground	8
Hotel, Lodge, or Resort	7
Organization Site	20
Other Recreation Concession	2
Recreation Resident Tract	54
Winter Sports	7
Information	6
TOTAL	244

Most of the use in the developed recreation setting takes place in camp and picnic grounds. These sites were used to near capacity on weekends in 1988.

It should be noted, however, that on some of the more popular weekends during the summer months, many camp sites are filled to capacity, with some visitors having to move to undeveloped sites or seek other camping opportunities. There are many private, local government, and state managed campgrounds within or in proximity to the Wenatchee National Forest. In most recreation oriented communities such as Chelan, Leavenworth, Cle Elum, and Yakima, these recreation sites supplement available Forest sites.

The resorts, organization sites, and recreation resident tracts which are under special-use permits to commercial entrepreneurs, organizations, and individuals provide additional recreation opportunities throughout the Forest.

At the present time, there are 45 campgrounds where a user fee is being charged. This fee ranges from \$3.00 to \$6.00 per day for individual family camp units. There are many multi-family units where the fee is adjusted according to the size of the unit and number of families it will accommodate.

In addition to the family unit campgrounds, the Forest has nine group reservation sites that can be reserved in advance at a fee that ranges from \$12.00 to \$50.00.

Camping fees are based on services and facilities provided and the average fees charged at state and private campgrounds in the general area. National Forest campgrounds are designed to offer a full spectrum of recreation opportunities. Campgrounds that offer showers, electrical hookups, and flush toilets will be provided in the urban, rural, or more developed roaded, natural recreation settings. Campgrounds that are more rustic with fewer facilities and conveniences will be provided in areas where the recreation setting is semi-primitive or roaded natural appearing.

There was \$253,000 of camping fees collected during the 1987 season and returned to the Ranger Districts for recreation program management.

In order for a campground to qualify as a fee site it must meet the following criteria: 1) designated camp units; 2) available drinking water; 3) access road; 4) refuse containers; 5) toilets; 6) fee collection facilities; and 7) reasonable visitor protection and campfire facilities.

The Forest is attempting to convert as many campgrounds as possible to the fee system in order to increase revenues and improve the facilities and service to the public.

The developed family campground sites listed in Table III- 1 have a total site capacity of 12,480 People at One Time (PAOT). This equals a potential output of 3,200,000 Recreation Visitor Days (RVD's) a year. The campground use for 1986 was 1,250,000 RVD's which indicates there is 1,950,000 potential surplus RVD's for the Forest at the present time. The majority of this

RECREATION SETTING

capacity is available mid-week. Developed sites receive heavy use on weekends and mid-week during late July and early August.

Almost all of the campgrounds on the Forest are in need of major rehabilitation work. This work is planned for completion through the Recreation Capital Investment program over the next 10 years. The larger, more highly developed sites will be upgraded with more services and some sites will be expanded to meet the growing demand for high quality recreation opportunities.

The 1979 State-wide Comprehensive Outdoor Recreation Plan (SCORP) for the State of Washington lists the supply level in number of camping units for the Wenatchee National Forest Zone of Influence (Chelan, Douglas, Okanogan, Kittitas, and Yakima Counties) as follows. Non-Forest Service sites are: local government - 332, State - 1,546, and private - 2,898, for a total of 4,776 units. Based on 5 PAOT per unit, this is equal to a capacity of 23,880 PAOT. Adding in the Forest's 12,480 PAOT for family camping units gives a total of 36,360 PAOT capacity.

The combined Federal, State and County facilities provide opportunity for 4,725,000 RVD's per year. The projected demand for camping in the zone of influence to the year 2000 is about 2,000,000 RVD's per year. Based on these figures, there is adequate existing and planned development to meet projected demand.

Developed Winter Sports Sites

The Forest Service objective for downhill skiing is to provide the opportunity to the private sector, through special-use permits, to develop successful ski areas which enhance the total outdoor recreation opportunity spectrum for the general public. There are seven sites on the Forest and current emphasis is on expansion of the Mission Ridge and White Pass Areas. There has also been some discussion with proponents concerning the expansion of the Crystal Mountain Ski Area in the upper reaches of the American River drainage. The Stevens Pass Ski Area Master Plan includes a potential development area in the Mill Creek drainage east of Stevens Pass.

The Forest supports new development where demand for winter recreation exceeds the current supply. However, new development will not occur on sites with poor potential for providing consistent, high quality recreation opportunity, or on sites with extremely high, unmanagable avalanche hazard.

The Chiwaukum Mountains in the vicinity of the Dardanelles on Highway 2 is the most promising potential ski area that has been inventoried. If this potential is pursued, it would be subjected to thorough environmental analysis as required by the National Environmental Policy Act. The analysis would include full public involvement.

The seven downhill ski areas offer a variety of skiing opportunities and challenges in alpine, subalpine, and low elevation settings. Stevens Pass, Snoqualmie Pass, and Pack West Ski Areas are administered by the Mt. Baker-Snoqualmie National Forest. White Pass and Mission Ridge are large developments, administered by the Wenatchee National Forest, that draw skiers from all over the Pacific Northwest. Chelan and Leavenworth Ski Areas are modest operations serving very local clientele.

The developed winter sports sites that are administered by the Wenatchee National Forest received the following use in the winter of 1985/1986:

<u>Name</u>	<u>Use In Recreation Visitor Days</u>
Chelan	5,200
Leavenworth	1,500
Mission Ridge	44,000
White Pass	40,800
Total	91,500

The White Pass Ski Area is located primarily on the Gifford Pinchot National Forest, but due to the proximity to Wenatchee National Forest administrative sites, it is administered by the Wenatchee. This ski area also operates one chairlift during the summer season as a tourist attraction. Portions of the Snoqualmie Pass, Pack West, and Stevens Pass Ski Areas are within the administrative boundaries of the Wenatchee National Forest but are administered by the Mt. Baker-Snoqualmie National Forest.

This exchange of administrative duties also provides a more balanced workload between the three Forests involved.

Developed winter sport sites are located at higher elevations and thus are subject to adverse weather and possible avalanches. The Mission Ridge area has trained personnel who use several methods of controlling avalanches. One method is the use of hand placed explosives in predetermined high hazard areas. The other method is skier control by trained personnel. Avalanche control is usually done after major snowstorms or when weather conditions create a high avalanche hazard.

The White Pass Ski Area has terrain and weather conditions which can contribute to avalanche hazards but the use of explosives is seldom required.

c. DISPERSED RECREATION

Dispersed recreation refers to those recreation activities that occur outside of developed sites such as camp or picnic grounds, resorts, organization sites, etc. It includes such activities as camping in undeveloped areas, hiking, off-road vehicle use (ORV), fishing, hunting, horseback riding, mountain climbing, cross-country skiing, gathering fuelwood, gathering berries, boating, driving for pleasure, etc. Recreational activities within wilderness areas are reported under Wilderness and are considered separate from dispersed use. Dispersed use occurs over the entire range of landforms, climate, and vegetative characteristics described at the beginning of this section.

Dispersed recreation outside of wilderness is divided into roaded and unroaded. The dispersed roaded area is comprised of the Roded Natural, Modified, and Rural ROS classes (See Table III-2 for definitions), distributed over 33 percent of the total Forest land area.

The unroaded area outside of the wilderness is made up of the areas having Primitive (P), Semi-primitive Non-motorized (SPNM) and Semi-primitive Motorized (SPM) ROS classes.

Table III-2 indicates that the majority of the vehicle oriented visitor use is taking place in the Roded, Natural and Roded Modified areas. These areas are mainly along the roads that have been and are being used for timber harvest such as the Swauk Corridor, Entiat River, Chirwawa, American River, Tieton River, and other major drainages. Although there is some evidence of resource utilization, resource managers have paid close attention to good visual management principles and most of the areas have retained their natural appearing character.

RECREATION SETTING

Based on the current inventory, dispersed recreation use outside of the 841,034 acres of wilderness on the Forest is distributed as follows:

TABLE III-2
DISPERSED RECREATION USE BY
RECREATION OPPORTUNITY SPECTRUM (ROS) CLASSES
1986

ROS CLASS	DESCRIPTION	RVD's	PERCENT OF USE
Primitive (Non-Wilderness)	An essentially unmodified environment, where trails may be present but structures are rare, and where the probability of isolation from the sights and sounds of man is extremely high.	418,500	18
Semi-Primitive Non-Motorized	A predominantly unmodified natural environment of a size and location that provides good to moderate opportunity for isolation from the sights and sounds of man.	80,500	4
Semi-Primitive Motorized	A predominantly unmodified natural environment in a location that provides good to moderate isolation from the sights and sounds of man.	247,300	11
Roaded, Natural and Roaded, Modified	A predominantly natural environment with evidence of some resource utilization.	1,190,000	53
Rural	Areas characterized by a substantially modified natural environment.	324,700	14
		TOTAL	1/ 2,261,000 100

1/ Does not include wilderness or developed site use

Table III-3 indicates the projected demand for Dispersed Recreation in terms of Roaded, Unroaded-motorized and Unroaded-non-motorized kinds of uses.

The supply, however, will vary over time as the inventory shifts from an unroaded condition to a roaded condition. Our current supply for each of these categories exceeds the projected demand through the year 2030.

TABLE III-3
DISPERSED RECREATION PROJECTED DEMAND
IN MILLIONS OF RECREATION VISITOR DAYS

	DECADE 1	DECADE 2	DECADE 5
<u>ROADED</u> Estimated Projected Demand	1.998	2.126	2.630
<u>UNROADED MOTORIZED</u> Estimated Projected Demand	.279	.301	.405
<u>UNROADED NON-MOTORIZED</u> Estimated Projected Demand	.099	.106	.143

Some types of dispersed recreational activities are as follows:

Driving for Pleasure

Within the Forest boundaries and surrounding areas, many opportunities exist for driving in a scenic rural or urban setting. The Forest manages some road corridors to preserve their scenic quality. Refer to Table III-8 for details. Some 4,667 miles of various types of roads are available for travel in the Forest's roaded natural setting. There were about 540,900 Recreation Visitor Days of use for this activity reported for 1986.

Off-Road Vehicle (ORV) Use

There were 116,700 Recreation Visitor Days use for this activity reported for 1986. The Forest has had various off-road vehicle plans for more than a decade. Over the years, ORV routes have been adjusted to meet changing conditions and needs. The current plan, adopted in 1977 after much public and other agency involvement, has been revised to take advantage of ORV opportunities while protecting basic resources. Mountain bicycling is a new and growing non-motorized use on National Forest trails.

Three and four-wheeled machines are becoming very popular but in most areas the existing trail system cannot physically accommodate their use. The trails are usually too narrow, therefore, the opportunity for their use is limited at this time.

Approximately 813 miles of trail outside of wilderness are open to motorized ORV use. These trails are open to hikers and horseback riders as well. There are an additional 307 miles of trail outside of wilderness open to hikers and horseback riders but closed to motorized use. Of the total trail miles on the Forest, about 33 percent are available for motorized means of transport (primarily trailbikes).

Water Activities

The Forest has several large lakes and many rivers and streams which attract a variety of water-oriented activities. Fishing is a major activity with over 183,000 Recreation Visitor Days in 1986. Much of the demand for power boating, water skiing, and sailing is met on Lake Chelan and reservoirs including Keechelus, Kachess, Cle Elum, Rimrock, and Bumping Lake. Quality varies because of fluctuating water levels resulting from draw-downs for irrigation. Lake Wenatchee is not as popular because of its smaller size, low water temperatures, and the strong winds that often occur there.

There are 235 small lakes and 6 major irrigation reservoirs inventoried on the Forest. Many of the lakes are in wilderness. Of the lakes outside of wilderness, 12 are accessed solely by trail.

River floating by various means has become increasingly popular and continued growth of this sport is expected. Several commercial enterprises are available and the most popular stream on the

Forest has been the Tieton River where 14 to 16 special-use, commercial rafting permits are issued annually. Heavy river floating use also occurs on rivers outside of the National Forest, notably on portions of the Yakima and Wenatchee Rivers. This results in increased use of National Forest campgrounds in the vicinity, such as those in the Icicle Creek drainage. As many as 60 different commercial rafting companies have been operating on the Wenatchee River near Leavenworth over the past four years.

Camping

Many visitors seek a dispersed camping opportunity where they provide and arrange their own facilities. They may be isolated from others or camp in their own small group. Most of the Forest is open to and suitable for this type of camping. Dispersed camping is a very popular activity in small spots along lakes, streams, or roads. Conflicts occur when campers use fire prone areas, pollute streams, disturb wildlife, or damage vegetation and scatter litter.

Some of the more popular dispersed camping areas on the Forest are the Little Naches River drainage and the Taneum-Manastash area. There are many suitable sites where camping impact on the physical and biological environment are low.

In some locations, such as the Icicle drainage, suitable dispersed camping sites are limited as logging company inholdings are sold and subdivided. These sites are then no longer available for public recreation use. This adds to the cumulative effect of increased use on National Forest lands.

Hunting

Hunting for big and small game, as well as upland game birds, attracted 239,600 Recreation Visitor Days use in 1986. Hunting accounts for some of the heaviest use that occurs on some parts of the Forest. This includes an early high country deer hunt in the Phelps Creek Area on Lake Wenatchee and hunting for elk on the Naches Ranger District.

Snow Activities

The Forest is expanding dispersed winter recreation opportunities by developing groomed snowmobile trails (445 miles), marked cross-country ski routes (40 miles), and snowshoeing areas. During 1986, snowmobiling use amounted to 77,300 RVD's and cross-country skiing and snowshoeing amounted to 180,800 RVD's.

There are 24 Sno-Park sites within the Forest. These Sno-Parks are planned, developed, and maintained in cooperation with the Washington Department of Transportation and the Washington Parks and Recreation Commission. Snow is regularly plowed from these areas along travel corridors in the snow belt. The most popular Sno-Parks are along the U.S. Highway 97 Corridor, in the Chiwawa Loop Road area around Lake Wenatchee, and in the Interstate 90 Corridor east of Snoqualmie Pass. The more highly used sites, such as the one on Swauk Pass, also have sanitary facilities provided during the winter months. Funds for construction and maintenance of these sites are derived from the sale of snowmobile permits, parking permits, and a percentage of the Washington State gas sales tax.

Dispersed winter recreation has an inherent risk of avalanches in the back country and it is not as practical to control as is done on the developed ski areas. However, the Forest Service, the U.S. Department of the Interior, and the Washington State Department of Transportation, jointly participate in funding an avalanche hazard forecast center based in Seattle. The Forest also has a weather station on the Mission Ridge Ski Area which contributes data for forecasting avalanche hazards. These are broadcast over local radio stations and printed in local papers.

d. TRAILS

Trails provide access for recreation in the more remote and undeveloped areas on the Forest. The mode of transportation allowed on them is a major issue on the Forest.

There are 2,463 miles of trails on the Forest. Approximately 48 percent of the Forest trails are in wilderness. The Forest Service is currently working with users to develop 4-wheel drive

routes, trail bike, cross-country ski, and snowmobile routes. Use of trails by all types of users is steadily increasing. The planning and management of this trail system requires active participation by user groups, a requirement not difficult to achieve in view of the high interest shown.

With the increase in population in the Puget Sound area, trail use has increased dramatically. More and more people are using the backcountry to vary their recreation experiences. The trail system provides the access to accommodate this increasing use.

The trail system evolved along traditional travel routes often without planning or consideration for protection of the area being served. Many of the trails now in use on the Forest were developed years ago for fire fighting access, grazing, or mineral exploration, and were located and built by the Civilian Conservation Corps, miners, sheepherders, and other users. Information on routes is published in numerous guide books making remote routes instantly popular.

With recreation now a dominant use of trails, a trail is no longer considered just a means of getting from here to there but is a recreation facility itself. Development and management of trails influences how we will manage an area. From the users' viewpoint, the trail should provide the challenge, variety, and views that they seek.

On the Forest, there are 293,199 acres of intermingled private or State land, much of it the result of railroad land grants in a checkerboard ownership pattern. As a result, many trails cross private land where there are no easements. Major landowners, such as Burlington Northern and Boise Cascade, permit public use of these trails but are not willing to grant permanent easements or alter their management practices to specifically protect trails. The exception is the Pacific Crest National Scenic Trail where Burlington Northern has granted an easement to the United States (September 10, 1973) with reservations for harvesting timber and the right to cross and recross the trail.

There are approximately 93 miles of trail covered by temporary private land easements or agreements. These cumulatively affect 350 miles or 28

percent of the trail system outside of wilderness areas. Should the private owners close these trails, it would have a severe impact on access to the Forest.

Project work such as timber sales, road and campground construction, mining, and range improvements can adversely affect trails. The effect will be addressed in the project environmental analysis and mitigating measures will be developed if the trail is to be retained. Forest policy is to restore trails dislocated by management activities or to replace them with an equal mileage of new trail elsewhere on the Forest.

Trails on the Forest provide a wide variety of opportunities for various user groups. Trail plans will include trailhead and camp area plans, plus plans to protect "natural" attractions such as lakes, meadows, and mountain passes.

The Wenatchee National Forest has ample potential to meet the annual construction/reconstruction miles assigned in the Regional Plan.

Trails are addressed by category as follows:

Wilderness Trails

Existing wilderness trails will be managed in accordance with standards and guidelines by Wilderness Recreation Opportunity Class. Relocation, reconstruction, or obliteration of trails will be done to meet wilderness management objectives and to correct safety problems. Most trails are open to pack and saddle stock unless specifically closed by order. There are 1,188 miles of inventoried trail in wilderness. These trails are not available for mechanized or motorized equipment use.

Pacific Crest National Scenic Trail

A total of 153 miles of the Pacific Crest National Scenic Trail traverse portions of the Forest. This trail is used as a major hiking route reaching from Canada to Mexico and is not open to use by motorized or mechanical equipment.

Non-Wilderness Trails

There are 1,275 miles of inventoried non-wilderness trails on the Forest. Of this, 813 miles are classified as multipurpose which means they are open to horses, hiking, and motorized trail bike use. There are 118 miles closed to motorized bikes but open to horse, mountain bikes, and hiker use.

4X4 Routes

Four-wheel-drive routes, by technical definition, are very low standard roads. There are approximately 120 miles of such routes on the Forest. These routes are generally used by short wheel-base vehicles. The areas that are most popular for this type of recreation are Table Mountain, Manastash Ridge, Clover Springs, and Divide Ridge.

Off-Road Vehicle (ORV) Trails

In Washington State, there are several governmental agencies which manage land in large tracts to provide for ORV recreation. These agencies can be grouped into three categories: Federal, State and local. The Forest Service is the principal Federal agency with designated ORV facilities in the State of Washington. Of seven National Forests in Washington, two provide almost 87 percent (2,290 miles) of the total Federal trail bike and four-wheel drive trail supply. Thirty-nine percent of the State total inventoried ORV multiple use trails occur within the Wenatchee National Forest.

In addition to working with Yakima and Kittitas Counties, the Forest has worked directly with Washington State Interagency Committee for Outdoor Recreation (IAC) and representatives of ORV users. The results have been 43 supplemental agreements with a value of \$1,446,939. All of these project areas are heavily used by hikers, horsemen, and trail bikers for a variety of activities such as backpacking, sightseeing, fishing, hunting, and trail riding. The funds used are derived through direct assessments to ORV users through license fees and gas taxes.

IAC has three types of supplemental agreements: one for planning, one for development, and one for maintenance. The planning agreement provides funding for comprehensive plans, which include environmental analysis, trail condition survey, and project survey and design. Development agreements provide project construction funds. Trail maintenance funds are used as supplemental funds for emergency purposes on those trails where IAC funds were used for reconstruction.

National Recreation Trails

The Forest has three trails designated as National Recreation trails: Domke Lake No. 1280 (Chelan Ranger District); Silver Falls No. 1442 (Entiat Ranger District); and Boulder Cave No. 962 (Naches Ranger District). This designation indicates these trails are popular, close to urban areas, open for a long season of use, attractive, and usually short.

Snowmobile Routes

The Forest has entered into a cooperative agreement with the State of Washington Parks and Recreation Department for grooming snowmobile routes and installation of appropriate trail signs on approximately 450 miles of winter trails. Four ranger districts participate in this program, with grooming done by Forest Service personnel on two of the districts. The other two districts administer permits for grooming done by the Yakima County Parks and Recreation Department and by a snowmobile club.

Snowmobile trail mileage varies from year to year depending on logging activities and snow conditions. All groomed trails are on roads rather than trails. The annual budget to groom these trails come from assessments on snowmobiles through State license fees.

Cross-Country Ski Trails

Cross-country ski trails have been developed and maintained over the years by the Forest Service and volunteers. There are approximately 119 miles of cross-country ski trails on the Forest. Snow-covered Forest roads provide many additional miles of skiing opportunities.

2. ROADLESS AREAS

Inventoried roadless areas are undeveloped Federal land which must be more than 70 percent Federally owned. The area must contain at least 5,000 acres and must not have improved roads maintained for vehicles intended for highway use. Exceptions are areas less than 5,000 acres that are manageable in their natural condition due to physiography or vegetation, are contiguous to existing wilderness, or are of issue to the public. Management of the inventoried roadless areas within the Alpine Lakes Management Area is directed by the Alpine Lakes Management Plan (see Alpine Lakes Area Management Act of 1976, PL 96-35). The Washington State Wilderness Act of 1984 designated 340,975 acres of inventoried roadless area as wilderness. Remaining roadless areas are listed here in brief and a more detailed description may be found in Appendix C.

Figure III-5 shows the current wilderness area and inventoried roadless areas. Table III-4 lists the roadless areas, location by Ranger District, and size in net National Forest acres.

Wilderness areas are discussed separately in this document.

3. WILD, SCENIC, AND RECREATIONAL RIVERS

On October 7, 1968, Congress enacted the Wild and Scenic Rivers Act (PL 90-542) in an attempt to protect certain outstanding free-flowing rivers that remain in the United States. The objectives of the Act were to keep these rivers or river segments in a free-flowing condition, and to recognize their importance to our natural and cultural heritage through the institution of a national Wild and Scenic River System. The Act also authorized eight rivers within the Nation for inclusion in the Wild and Scenic Rivers System, and established the methods for designating additional components to the system. Twenty-seven rivers were identified for further study. This number was augmented by an additional 29 study rivers through the January 3, 1975 amendment to the Act. However, none of the rivers involved in the legislation were located on the Wenatchee National Forest.

In the late 1970's, the Heritage Conservation and Recreation Service (HCRS) branch of the National Park Service conducted a nationwide inventory of rivers having potential for inclusion in the Wild and Scenic Rivers System. The purpose of the inventory was to ensure that the Nation's best rivers, representing a diversity of river types, were considered for inclusion within the National Rivers System. The importance of this inventory was highlighted in 1979, when then President Carter, in his Environmental Message, directed that "...federal land management agencies shall assess whether rivers located on their lands and identified in the National Inventory prepared by the Heritage Conservation and Recreation Service are suitable for inclusion in the Wild and Scenic Rivers System; if so, these agencies shall take prompt action to protect the rivers - either by preparing recommendations for their designation or by taking immediate action to protect them..."

The inventory was later revised and completed by the National Park Service in 1982. Joint guidelines were also established at that time by the Department of Agriculture and the Department of Interior for determining the eligibility, classification and management of river areas.

Consideration of potential Wild and Scenic Rivers has subsequently become an inherent part of the Forest Service land and resource management planning process. Within this process, river studies are to be conducted to assess the eligibility of the rivers for designation, and to evaluate the potential physical, biological, economic and social effects of adding the river or rivers to the National System. Eligibility is to be based upon the following criteria set forth under section 1(b) and 2(b) of the Wild and Scenic Rivers Act and as supplemented by the USDA-USDI Guidelines:

- 1) The rivers are free-flowing; and
- 2) They possess one or more outstandingly remarkable scenic, recreational, geologic, fish, wildlife, historic, cultural, or ecological values.

On the Wenatchee National Forest, the Nationwide Rivers Inventory (NRI) was used as a starting point for identifying potentially eligible rivers. The Chiwawa, White, Wenatchee and Yakima Rivers were listed in the inventory. The initial Forest planning effort also included the Entiat River and two tributaries, in response to a proposal submitted at that time by a coalition of environmental groups.

As a result of public comments received after release of the DEIS, the consideration of potentially eligible rivers on the Forest was expanded to include:

1. All rivers identified by the public which appeared to meet the criteria outlined in the joint USDA/USDI Guidelines for Evaluating Wild, Scenic and Recreational Rivers.
2. Those rivers identified through in-Service study, which had characteristics similar to the rivers identified in the NRI, and which appeared to meet the criteria of the joint agency guidelines. This study included consultation with other agencies and review of the Pacific Northwest Rivers Study.

A total of 33 rivers, river segments and creeks were ultimately examined for eligibility, through a two phase study (the details, process and results of the study are described in Appendix E). Of these 33, ten were determined to meet the eligibility criteria. Each eligible river or river segment was then assigned to one of three potential classes, based on the condition of the river and the adjacent lands as they presently exist. These classifications are defined in the Wild and Scenic Rivers Act as follows:

- a. Wild river areas - Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.
- b. Scenic river areas - Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.
- c. Recreational river areas - Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Through this process, Table III-5 was developed, which lists the eligible rivers on the Wenatchee National Forest, with the highest potential classification for each segment:

TABLE III-5
RIVER CLASSIFICATION ELIGIBILITY
UNDER THE WILD & SCENIC RIVERS ACT

River ¹	Segment	Classification Eligibility	Length/Miles		
			NF	Other	Total
AMERICAN	Headwaters to confluence w/Rainier Fork	Wild	6.0		6.0
	Confluence w/Rainier Fork to confluence w/ Bumping River	Scenic	16.0		16.0
CLE ELUM	Headwaters to Alpine Lakes Wilderness boundary	Wild	4.0		4.0
	Alpine Lakes Wilderness boundary to above Lake Tucquala	Scenic	2.0		2.0
	Above Lake Tucquala to Salmon La Sac bridge	Scenic	4.0	10.0	14.0
	Salmon La Sac Bridge to head of Lake Cle Elum	Recreational	3.5	1.0	4.5
WAPTUS	Headwaters to Alpine Lakes Wilderness bndry.	Wild	12.0		12.0
	Alpine Lakes Wilderness boundary to confluence with Cle Elum River	Wild	1.0		1.0
ICICLE	Headwaters to Alpine Lakes Wilderness bndry.	Wild	12.0		12.0
	Alpine Lake Wilderness Boundary to City of Leavenworth water intake	Scenic	7.5	6.5	14.0

	Goose Cr. to confluence w/ Wenatchee River	Recreational	2.75	3.25	6.0
ENTIAT	Headwaters to Glacier Peak Wilderness boundary	Wild	12.5		12.5
	Glacier Peak Wilderness boundary to Cottonwood trailhead	Wild	4.0		4.0
	Cottonwood Trailhead to private land boundary	Scenic	15.0		15.0
WENATCHEE	Lake Wenatchee to Tumwater Campground	Recreational	9.25	11.75	21.0
	Tumwater Campground to National Forest boundary	Recreational	5.0	2.0	7.0

¹ The Yakima River was not included in the eligibility determination, due to the fact that National Forest lands make up less than one percent of the ownership in the Yakima drainage

Present management of these rivers and their adjacent corridors will continue to provide for the protection of the special river values to the standards of their highest potential classification, until such time as Congress formally determines their status as Wild and Scenic Rivers.

A full description of the affected environment of each river is provided in Appendix E, as are the results of the suitability study that was also carried out.

4. CULTURAL RESOURCES

The cultural resource base of the Wenatchee National Forest includes a diverse and unusually rich range of historic and prehistoric artifacts and sites. These include: 1) historic cabins, trails, mines, ditches, railroad grades, emigrant trails, original highway grades, mills, and homesteads; 2) historic Forest Service structures including guard stations, lookout towers, corrals, camps, administrative centers, and Depression-era campgrounds and buildings; and 3) prehistoric campsites, villages, graves, quarries, pictographs, workshops, trails, rock shelters, and religious sites.

Many of these properties are unique. They provide the sole record of former habitats, ways of life, and past human activities. They help provide an understanding of the human adaptations, uses, and alterations of the Cascade Mountain environment.

The cumulative effects of landscape modifications, private land developments and major hydroelectric projects have destroyed much of this record in the Columbia River system. What remains on the Wenatchee National Forest may be a major portion of the historical record of central Washington. Much of it is unique and unduplicated elsewhere.

In several instances, the cultural resources on the Forest are also part of what was once a larger cultural complex, which encompasses portions of the Columbia Plateau and Puget Sound. The cultural resources on the Forest are often of local or state significance and, in about 20 percent of the cases, are of National Register significance (based on records on file at the Wenatchee National Forest Supervisor's Office).

In accordance with the National Historic Preservation Act of 1966 as amended, the National Environmental Policy Act of 1969, Executive Order 11593, as well as a series of implementing regulations and policy direction, the Forest has undertaken a program to identify, evaluate, preserve, protect and interpret the cultural resources.

A cultural resource overview, pulling together most of the recorded information relating to the prehistoric and ethnographic uses of the Forest, has been completed and is available for review. An overview of the historic resources of the Forest still needs to be completed.

Between 1976 and 1985 cultural resources were inventoried on about 123,372 acres of the Forest, or 6 percent of the total Forest acreage. Most field examinations have been done in conjunction with other Forest activities. These surveys have determined the location and nature of cultural sites within potential project areas. At the present rate, project inventory will be completed at a rate of about 30,000 acres per year. Most of this will be in support of the timber sale program.

Inventories have been mostly confined to surface examinations only. Archaeological test excavations have been carried out at five sites on the Forest to determine their subsurface extent and potential eligibility for inclusion in the National Register of Historic Places. These sites were selected for testing because of their relationship to planned timber sales and campground developments. Ultimately, the data retrieved may provide important contributions to archaeological research.

In addition to field inventory, on-going literature search and interviews with knowledgeable local residents has resulted in the identification of a total of 597 known and suspected sites as of 1985.

CULTURAL RESOURCES

Of these, 233 have been documented on site inventory forms or other agency registers. Of the 233 sites, 108 have been evaluated. Sixty-seven of these did not meet the criteria for inclusion in the National Register of Historic Places (State Historic Preservation Office Consultations 1976-1985), however, they may be candidates for future interpretive programs because of local interest.

Another 24 appear to be significant sites and will require more complete documentation and evaluation. Ten individual buildings or building groups (a total of 55 buildings) have been determined eligible for the National Register as part of the USDA Forest Service Pacific Northwest Region evaluation of Depression-era administrative structures.

The remaining sites include formally designated National Register or National Register eligible properties. In this grouping are portions of the Stevens Pass Historic District, the Liberty Historic District, and of the Yakima-Tieton Irrigation District. There are also several individual properties in the group, including the Salmon La Sac Guard Station, the Crow Cabin, the Tumwater Canyon Penstock Bridge, the Wallin Ditch, and the Old Tieton Road.

Table III-6 is a summary of the known and reported cultural resources of the Forest as of 1985. Historic sites are those associated with the period for which there are written records. In Central Washington, the historic era begins at roughly 1805 A.D., with the Lewis and Clark expedition on the lower Columbia River. Prehistoric sites are those predating this period, and are linked with the American Indians and their ancestors.

**TABLE III-6
INVENTORIED AND REPORTED CULTURAL SITES
1985**

Ranger District	Number of Inventoried Sites 1/		Number of Reported Sites and/or Use Areas 2/		Conditions of Remains			Interpretive Value		
	Historic	Prehistoric	Historic	Prehistoric	Poor	Fair	Unknown	Yes	No	Unknown

TOTAL	167	111	372	199	268	282	299	198	572	79

1/Includes Forest Service Site Inventories, University/WARC Inventories, State and National Registers.

2/These include sites situated on adjacent and intermingled private land.

The number of sites known and evaluated may represent only a small portion of the total of cultural resources that actually exist on the Forest. Prehistoric and historic land use patterns suggest a high probability for the occurrence of other significant cultural resources within the Forest.

Preservation and protection of the Forest's cultural resources is closely associated with the location of the resources, the nature of the management activities with which they interact, and the particular characteristics of their environmental setting. Impacts to cultural resources may be natural, project-related, or the consequence of public use.

Natural threats include weathering, insect infestation, erosion, moisture, tree fall, trampling by wildlife, and fire. These forces are especially likely to affect historic buildings, resulting in the loss or decay of structural elements and the ultimate demise of the building. On the Forest, most of the inventoried historic wood frame or log structures, aside from the administrative sites under current use, have experienced substantial decomposition. Erosion is a major factor in the irretrievable loss of archaeological data. At least two known Indian housepit/refuse sites on the Forest are experiencing severe degradation through river action. Regular maintenance work, rehabilitation, site stabilization, and data retrieval are just a few ways of preventing the further deterioration or loss of properties and data.

As lands are allocated to uses involving land and vegetation modification, the probability of adverse impacts on cultural resources increases. Studies on the Forest indicate certain locations have the greatest probability for overlap between cultural resources and other management activities (Wenatchee National Forest Sampling Design, 1983).

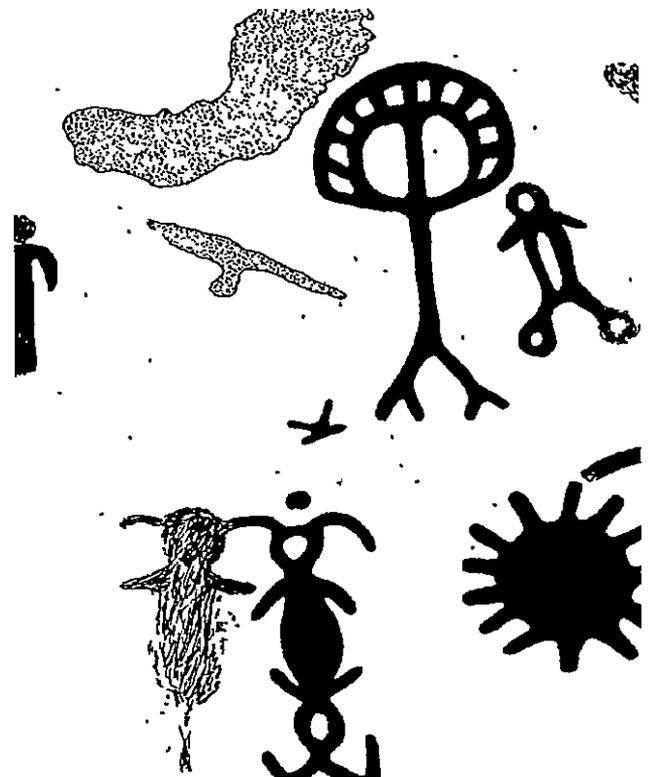

The most important step in the preservation and protection of significant cultural resources is systematic inventory well in advance of Forest projects. Proposed roads, trails, and project boundaries can often be adjusted with very little additional cost or impacts to the proposed projects if the need is determined during the very early planning stages. In this way, other uses can

frequently be carried out without endangering the historic qualities of nearby cultural sites.

Occasionally, public use may result in the deliberate destruction of cultural properties through vandalism, relic collecting, theft and carelessness. Archaeological sites are especially subject to the hazard of "pot hunting" (illegal relic gathering). This results in the loss of information vital to the reconstruction of prehistoric ways of life.

Several protective measures have been used to deal with this problem. These include maintaining the confidentiality of specific site locations, directing public use away from them, and periodic monitoring of sensitive areas. However, a more positive approach is also needed. This would involve education of the public to the values and fragility of the cultural resource

The management of cultural resources also has an effect on the management of other environmental components on the Forest. These effects may be mutually supportive, or may cause conflicts requiring resolution. Among these considerations are the level of significance of the property and its condition, suitability for scientific research or interpretive opportunities, importance to a community or ethnic group; accessibility, and compatibility with other activities.

CULTURAL RESOURCES

At this time, a Washington State Preservation Plan is being prepared under the direction of the Washington State Office of Archaeology and Historic Preservation. This plan should provide additional data and considerations of help in evaluating and developing management strategies for the cultural resources of the Wenatchee National Forest. There will be continuing coordination between the Forest cultural resource program and the State Plan when it becomes available.

The future demand for cultural resources is likely to be a function of three factors: recreational use, the specific association of a community or ethnic group with historic site or area, and the development and expansion of archaeological research. Since the Forest receives approximately 4.9 million Recreation Visitor Days use per year (Recreation Information Management 1986), it is likely that interpretive programs and designated historic points of interest would experience substantial public use.

The demand for protection and preservation of historic sites and areas because of community associations will probably continue at about the same rate as in the past. Salmon La Sac Guard Station, the Liberty Historic District, and Stevens Pass Historic District were all the products of community efforts to recognize historic values embodied in these properties (Wenatchee National Forest correspondence files). Generally, community associations develop as the Forest Service plans for the disposition of the sites and properties.

Representatives of the Yakima and Colville Indian Reservations have also expressed a concern for the protection of archaeological sites on the Forest. These properties represent a very special link between the Indians and ancestors who once occupied the Forest lands. A more detailed discussion of Indian concerns and interaction is presented in the American Indian Uses and Concerns section.

Research by the scientific community is expanding into the uplands, carrying with it the recognition of the exceptional value of hinterland sites to the reconstruction of prehistoric subsistence patterns. Many references to this research are on file at the

Wenatchee National Forest Supervisor's Office. The demand for the protection and preservation of all archaeological properties will remain high. Requests for research are not anticipated to be frequent, but one university has expressed an interest in conducting a field school at a Forest site if funding becomes available.

American Indian Uses and Concerns

The Forest is within the area ceded to the U.S. Government by the Yakima Indian Treaty, dated June 9, 1855. (Refer to the copy of the 1855 Treaty in Appendix G.) Originally, the Forest was home to the Yakima and Wenatchee tribes, who wintered in villages along the Columbia River and its tributaries. They traveled widely in spring, summer, and fall to gather berries, root vegetables and medicinal herbs, and to hunt and fish in the forested Cascade Mountains.

With the conclusion of the Yakima Indian Treaty and the subsequent Executive Order of July 2, 1872, most of the original Native American inhabitants of what are now Chelan, Kittitas, and Yakima Counties were resettled onto the Yakima and Colville Reservations. However, certain rights and privileges to the ceded lands were retained. Article 3 of the Yakima Indian Treaty states, "...has also the right of taking fish at all usual and accustomed places in common with the citizens of the territory, and of erecting temporary buildings for curing them; together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land...".

This places the Forest in a special position with respect to the Yakima and Colville Tribes. Coordination of the Forest programs and activities involves the Yakimas as adjacent neighbors. It recognizes the Tribes as concerned public interest groups and as people with ancestral ties to the land base of the Forest. It requires a special working relationship responsive to the rights and privileges of the Tribes as defined by the 1855 Treaty. This includes the accompanying responsibility by the U.S. Government to protect water quality and anadromous fish habitat on the Forest from environmental degradation (Northwest Indian Cemetery Protective Association, et al. v. R. Max Peterson, et al. 1983).

Certain additional uses of the Forest lands by the American Indians are authorized by the American Indian Religious Freedom Act (P.L. 95-341), which states that it shall be the policy of the United States to protect and preserve for American Indians their traditional religions. This includes, but is not limited to, access to sites, use and possession of sacred objects, and the freedom to worship through ceremonial and traditional rites (refer to a copy of this Act in Appendix G).

Currently, information with respect to location of traditional American Indian religious sites on the Forest is unknown. Members of the Yakima Indian Nation are reluctant to share this information because of its private nature. What is known is that many ceremonies and religious activities are directly related to the importance of certain food sources. Roots, salmon, venison, and berries are still served and eaten as part of traditional religious ceremonies (Galm, et al. 1981). Within the mid-Columbia region, many of the traditional food gathering areas (especially root localities) are now in private ownership. Consequently, many of the Indians obtain their traditional resources from federal lands.

With respect to the Forest, this has raised another concern. About 12 percent of the Forest is in non-federal ownerships. These exist largely as a checkerboard pattern in which alternate sections are owned primarily by large landowners. This condition is particularly noticeable on the Cle Elum, Leavenworth, and Naches Ranger Districts. Since this ownership resulted from the Railroad Land Grants, there is no relationship between the distribution of ownership and the location of traditional or critical food and materials collecting areas. Not infrequently these areas, such as Camas Meadows, occur on private land. These areas may be subject to severe alteration or closed to public entry. The private ownership and the cumulative effects of the management of these lands has and will continue to limit the traditional uses of these localities.

The relationship and interaction between American Indian rights and uses of the Forest and other Forest management activities is complex. Rights reserved to the Indians by the Yakima Treaty will affect Forest management activities, particularly those actions that could impact water quality and

anadromous fish habitat. Other Indian-related issues that may influence Forest programs are protection of wildlife resource values and ancestral sites; recognition of social/cultural/religious values with respect to the landscape and resources of the Forest; and assurance of access to traditional resource collection areas. Litigation with respect to Indian rights is ongoing in many areas of the United States and may result in future changes in management practices on the Forest.

5. SCENERY

The Wenatchee National Forest is well known for its outstanding mountain, valley, and lakeshore scenery.

The Cascades landscapes are distinctive in beauty and nature, with sweeping vistas and a variety of topography, ecotypes, and lifeforms. Natural appearing environments exist on much of the Forest, even where intensive commodity management is occurring. Approximately 63 percent of the Forest, including wilderness areas, are in a natural appearing visual condition.

Visual quality is classified according to the scenic variety of an area and how often it is seen by the viewing public. The most scenic classifications are Preservation, Retention, and Partial Retention. Definitions of Visual Quality Objectives and percent of land in each under current management are depicted in Table III-7. The Forest Plan will contain specific visual quality objectives for all areas of the Forest.

TABLE III-7
EXISTING VISUAL QUALITY OBJECTIVES
1985

VQO Objectives	Description	Percent of National Forest Land
Preservation (P)	Areas in which only ecological change has taken place except for trails needed for access. They appear to be untouched by human activities.	42
Retention (R)	Areas in which changes in the landscape are not visually evident to the average person unless pointed out. They appear to be natural.	21
Partial Retention (PR)	Areas in which changes in the landscape may be noticed by the average forest visitor but they do not attract attention. The natural appearance of the landscape still remains dominant. They appear to be minor disturbances.	24
Modification (M)	Areas in which changes in the landscape are easily noticed by the average forest visitor and may attract some attention. They appear to be disturbances but resemble natural patterns.	2
Maximum Modification (MM)	Areas in which changes in the landscape are strong and would be obvious to the average forest visitor. These changes stand out as a dominating impression of the landscape. Yet, they are shaped so that they might resemble natural patterns when viewed from 3-5 miles or more distant. They appear to be major disturbances when viewed at closer distances.	11

The most valuable scenery occurs on lands that are distinctive in character and highly visible. The Forest provides the public with seven wildernesses, six major reservoirs, including scenic Lake Chelan, several large natural lakes, including Lake Wenatchee, many free flowing rivers, five Washington State "scenic" designated highways, and numerous main travel routes penetrating the Forest toward recreation areas and wildernesses. Thirty-four viewsheds or travel routes have been identified as being important inventoried recreational travelways on the Forest. See Table III-8 for Visual Condition of Travel Routes and Viewsheds and Existing Visual Quality Levels. A viewshed is the total landscape seen, or potentially seen, from all or a logical part of a travel route, use area, or water body.

Visual condition of travel routes and viewsheds are a summary rating of the overall impression a visitor would have of the visual appearance of the lands seen in a total area. These are expressed in terms directly related to the amount and type of individual activity alterations found during Individual Activity Evaluations.

Visual Quality Levels are the output of the inventory process of the Visual Management System. A desired level of excellence is based on physical and sociological characteristics of an area.

TABLE III-8
VISUAL CONDITION OF TRAVEL ROUTES AND VIEWSHEDS
AND EXISTING VISUAL QUALITY OBJECTIVES

Present Inventories			Visual Quality Objectives		
No.	Viewshed or Travel Routes	Existing Visual Condition	Foreground	Middleground	Approx. Acres
1	Lake Chelan	Natural Appearing	Retention	Partial Retention	84,800
2	Railroad Creek	Natural Appearing	Retention	Preservation	14,600

27	North Fork Tieton	Altered	Partial Retention	Partial Retention	12,200
28	South Fork Tieton	Slightly Altered	Partial Retention	Modification	8,500
29	Tieton Road	Natural Appearing	Retention	Not Seen	6,400
30	Stevens Pass (Hwy-2)	Altered	Retention	Partial Retention	50,600
31	Swauk Pass (Hwy-97)	Slightly Altered	Retention	Partial Retention	31,100
32	Snoqualmie Pass	Heavily Altered	Retention	Partial Retention	21,500
33	Icicle Valley	Altered	Retention	Partial Retention	18,300
34	Cle Elum Valley	Slightly Altered	Retention	Partial Retention	31,500

Nineteen lakes and reservoirs have been identified as being important recreational lakes with high visual sensitivities. Many of the lakes are along travel routes. See Table III-9 and map, Visual Condition of Lake Viewsheds and Existing Visual Quality Objectives. Natural appearing settings are important to users and the demand for retention of these settings is great.

Concerned residents of communities within and adjacent to the Forest, such as Chelan, Cle Elum, Leavenworth, and Lake Wenatchee, have high expectations that a natural appearing Forest environment will be maintained. Outfitter guides, resorts, club sites, organizational sites, and recreation residences add to the public demand for natural settings.

Preservation of old growth for aesthetic reasons is an important value for many members of the public. Areas of old growth are characterized by mature and overmature trees with a multi-layered canopy. These areas show little evidence of man's activities. Section 9b of this chapter, Vegetation: Old Growth discusses old growth forests in more detail.

TABLE III-9
VISUAL CONDITION OF LAKE VIEWSHEDS
AND EXISTING VISUAL QUALITY OBJECTIVES

Present Inventories		Visual Quality Objectives	
Lakes and Surrounding Landscape	Existing Visual Condition	Foreground	Middleground
Antlon Lake	Altered	Modification	Not Seen
Domke Lake	Natural Appearing	Retention	Preservation
Fish Lake	Slightly Altered	Retention	Modification
Lake Wenatchee	Natural Appearing	Retention	Partial Retention
Beehive	Altered	Partial Retention	Not Seen
Manastash Lake	Natural Appearing	Retention	Not Seen
Bumping Lake	Natural Appearing	Retention	Preservation
Granite Lake	Natural Appearing	Partial Retention	Not Seen
Leech Lake	Slightly Altered	Retention	Not Seen
Dog Lake	Natural Appearing	Retention	Not Seen
Clear Lake	Natural Appearing	Retention	Partial Retention
Rimrock Lake	Natural Appearing	Retention	Partial Retention
McDaniel Lake	Slightly Altered	Modification	Modification
Bear Lake	Natural Appearing	Modification	Modification
Lost Lake	Natural Appearing	Partial Retention	Not Seen
Cooper Lake	Natural Appearing	Retention	Partial Retention
Cle Elum Lake	Slightly Altered	Retention	Partial Retention
Kachess Lake	Slightly Altered	Retention	Partial Retention
Keechelus Lake	Altered	Partial Retention	Retention

Wilderness, unroaded, non-motorized areas, and Research Natural Areas have a "preservation" Visual Quality Objective. The other inventoried visual quality objectives listed above apply to the rest of the Forest.

Approximately 68 percent of the commercial forest lands are inventoried as either "retention" or "partial retention".

The existing Alpine Lakes Plan, the Kittitas Plan, and the Swauk and the Entiat Visual Corridor Plans provide current visual quality standards and direction for meeting them. In other areas, the landscape is managed by visual quality objectives (Table III-7).

Impacts on the visual resource can be measured by analyzing two basic inventories. The first is an inventory of the visual characteristics of the present landscape measured on a scale ranging from "natural appearing" to "permanently modified".

Four main classes describe the existing visual condition of the Forest's landscape. These are listed below:

TABLE III-10
EXISTING VISUAL CONDITION
OUTSIDE OF WILDERNESS
1984

Description of Visual Condition	Total Forest Lands
Natural appearing landscape	63%
Activities have slightly altered the natural appearing landscape	15%
Activities have altered and heavily altered the natural appearing landscape	21%
Activities have permanently altered the natural appearing landscape (e.g., powerline corridors)	1%

A natural appearing landscape equates with preservation and retention visual quality objectives. Activities that have slightly altered the natural appearing landscape are associated with partial retention visual quality objectives. Activities that have altered, or heavily altered, the natural appearing landscape are associated with the modification and maximum modification visual quality objectives.

The second inventory method is the visual absorption capacity. It uses criteria for predicting the capability of the landscape to absorb visual alteration.

Factors used include slope of terrain, vegetative composition, soil color contrast, and the ability of an area to return to its natural appearance after alteration by human activity. The most critical visual factors are the steep and moderately steep slopes on commercial forest lands. Of the total commercial forest land, 15 percent is steep and 64 percent is in moderately steep landscapes. These areas are highly visible and, therefore, have the greatest potential for visual resource impact.

Recreation Information Management (RIM) data indicates that approximately 15 percent of the 5.0 million visitor days of recreational use in 1986 was driving for pleasure and viewing scenery. Public demand for scenic quality and concern for its maintenance is increasing and is expected to continue to increase over the foreseeable future. Visual quality concerns are highest along the major state routes that criss-cross the Forest; along collector roads accessing wilderness; and in areas near recreation sites or communities.

Recreationists intensively use the five interstate scenic highways, 5,110 miles of existing forest roads, and 2,463 miles of trails. These facilities traverse a wide variety of forest and non-forest lands. Of all these lands, the greatest potential for impact on the visual resource will be within roadless and commercial forest areas that are delineated as "retention" and "partial retention" in the Landscape Management Inventory.

There has been a trend toward increased timber harvest in higher elevation, steeper areas with high scenic values. Many of these distinctive areas are visible from scenic travelways and

recreation areas. Logging plans require careful design and sophisticated technology to preserve scenic values.

The cumulative effects of visual change is most noticeable in areas of mixed ownership where differences in cutting practices, road construction and development are accentuated. The prime example is the Snoqualmie Pass (I-90) viewshed. The combination of private land management and the Forest Service activities increases the alteration of the natural landscape. Recently, the Stevens Pass (U.S. 2) viewshed shows increased change of the natural landscape through both private and Forest Service vegetation management. The roadless areas are presently in a natural appearing state. These lands will be altered as the land becomes available for timber management.

Existing management direction can be expected to continue the historical trend of altering the overall visual condition by timber harvest during the next decade.

The valley bottom drainages contain most of the transportation corridors, utilities, residential development, and other intensive land uses. Some of the land is privately owned. The majority of the private land uses which impact scenic quality in these areas are controlled by the counties. Increased development is expected on private lands within the valley bottoms. Protection of scenic values can best be achieved through proper zoning and landscape ordinance.

6. WILDERNESS

Wilderness fulfills a strongly expressed social need, not only from those who partake of the wilderness experience, but also from those who, although they may never see or visit wilderness, have a "peace of mind" knowing it exists and is available for generations to come. According to the 1964 Wilderness Act, wilderness is an area where "man is a visitor who does not remain" and a place offering visitors an opportunity for solitude. Protection of the natural qualities of the area takes precedence over human and recreational use.

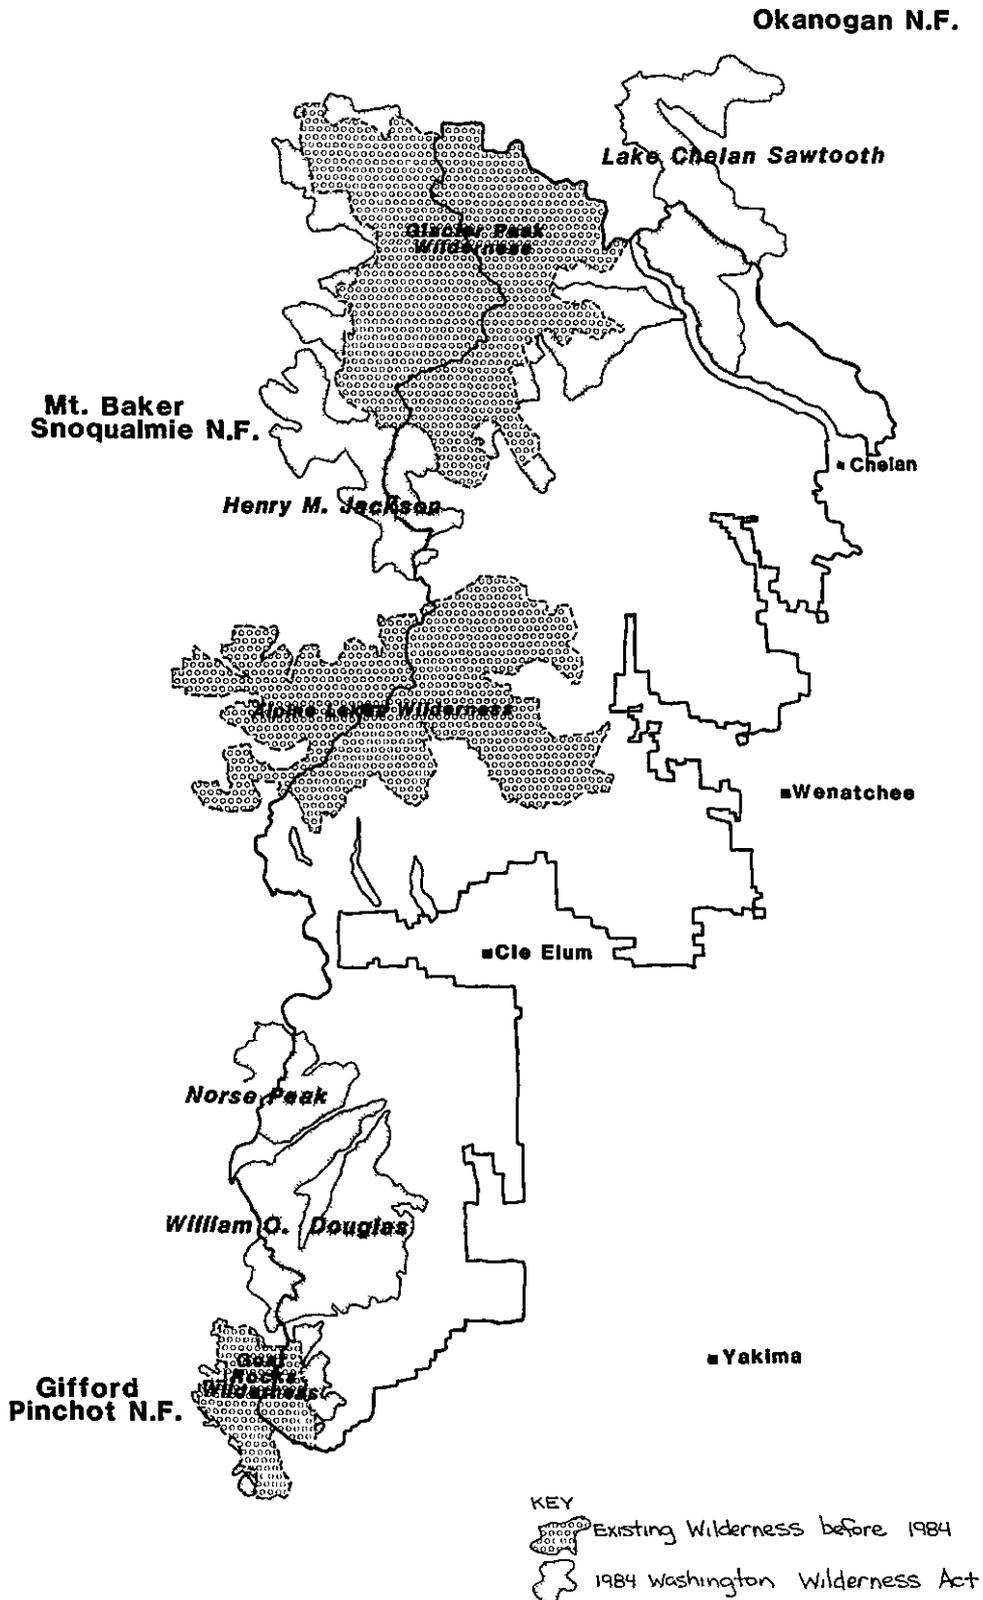

Wildernesses occupy 39 percent of the area on the Wenatchee National Forest and span a multitude of environments and elevations ranging from low, open, grassy slopes to timber stands of all ages and varied species; from subalpine and alpine areas to the rugged, rocky peaks of the Cascade Range. Some of these areas are inherently fragile and easily disturbed such as lakeshores, meadows, and thin-soiled steep slopes.

Wilderness on the Wenatchee National Forest was designated by Congress with the Wilderness Act of 1964 (Goat Rocks and Glacier Peak Wilderness Areas), the Alpine Lakes Area Management Act of 1976 (Alpine Lakes Wilderness), and the Washington State Wilderness Act of 1984 (Lake Chelan-Sawtooth, Henry M. Jackson, Norse Peak and William O. Douglas Wilderness Areas). The 1984 Act also added 62,712 acres to Glacier Peak Wilderness and 11,173 acres to Goat Rocks Wilderness.

Glacier Peak, Alpine Lakes, Henry M. Jackson, and Norse Peak Wilderness Areas extend across the Cascade Crest into the Mt. Baker-Snoqualmie National Forest while the William O. Douglas and Goat Rocks Wilderness Areas extend into the Gifford Pinchot National Forest. In the north, the Wenatchee and Okanogan National Forests share the Lake Chelan-Sawtooth Wilderness (Figure III-6). Managers of neighboring Forests worked together to develop uniform direction to be used by each forest for the management of these shared wilderness areas.

FIGURE III-6
WILDERNESS AREAS
WENATCHEE NATIONAL FOREST

WILDERNESS

Following is the total area for each of the wilderness areas and the amount that lies within the Wenatchee National Forest:

**TABLE III-11
WILDERNESS AREA ACREAGE**

Wilderness	Total Acres	Wenatchee National Forest Net Acres
Lake Chelan-Sawtooth	145,667	56,414
Glacier Peak	576,865	289,001
Henry M Jackson	103,591	27,221
Alpine Lakes	393,360	244,057
Norse Peak	50,923	36,295
William O. Douglas	167,195	151,730
Goat Rocks	105,633	36,316
TOTAL	1,543,234	841,034

The Forest's wilderness areas contain a vast number of lakes and tarns, and afford many challenges for rock climbing, mountaineering, and cross-country travel. They also provide many opportunities for solitude.

The designation as wilderness carries with it some limits as to the kinds and amount of uses permitted which differ considerably from restrictions outside of wilderness. Motorized use is prohibited; group sizes and numbers of people visiting selected areas are limited; use of pets, recreation stock, fires, and firewood are restricted; and camping is not allowed in some fragile locations. Road construction and timber harvest are prohibited.

The wilderness environment for each wilderness area is briefly described below. In addition, specific features and uses for each, as they pertain to the Wenatchee National Forest only, are included.

a. LAKE CHELAN-SAWTOOTH

LOCATION: Wenatchee and Okanogan National Forests; Chelan, Twisp, and Winthrop Ranger Districts

SIZE: 145,667 acres

KEY ACCESS POINTS: Along Lake Chelan, the trailhead at Prince Creek accesses Prince Creek Tr. #1255 and Lakeshore Tr. #1247; in the northern portion, access is possible via the Twisp River Road, Libby Creek Road, Buttermilk Creek Road, and Wolf Creek Trail.

MILES OF TRAIL: Approximately 194 miles.

ELEVATION RANGE: From 1,100 feet on the surface of Lake Chelan to 8,974 feet on North Gardner Mountain.

GENERAL DESCRIPTION: Located in Chelan and Okanogan Counties, the Wilderness borders include the north shore of Lake Chelan, the North Cascades National Recreation Area to the northwest, and the Sawtooth Mountains to the northeast. Fifty-one mile long Lake Chelan is a significant feature of interest adjacent to the Wilderness. A diversity of landforms is found in the area including sharp rocky canyons, deep mountain valleys, and jagged peaks. A great variety of habitat is represented by alpine meadows, subalpine fir forests, lodgepole pine thickets, grassy openings, large Douglas-fir and Englemann spruce, hardwoods, and sagebrush. Numerous high mountain lakes are found in the area. Wildlife includes mule deer, elk, mountain goat, cougar, and black bear. Bald and golden eagles are commonly seen in winter months. Rattlesnakes are numerous on dry slopes. Extensive mineral exploration and development has occurred over the last hundred years.

This moderately visited area, although rugged, offers considerable opportunity for cross-country travel across large expanses of open, wildflower adorned meadows. Its location affords a sunnier, drier climate than the other wilderness areas which lie straddled along the Cascade Crest. Surprise Lake is a major attraction. Portions of this Wilderness can be accessed by powerboat where it borders Lake Chelan.

b. GLACIER PEAK

LOCATION: Wenatchee and Mt. Baker-Snoqualmie National Forests; Lake Wenatchee, Entiat, Chelan, and Darrington Ranger Districts

SIZE: 112,607 acres of additions
464,258 acres original area
576,865 acres total Wilderness

KEY ACCESS POINTS: On the west side, Highway 20 accesses FS Road numbers 23 and 49 and Highway 530 accesses FS Road #26; and on the east side, U.S. Highway 2 to State Highway 207 and FS Roads #6400 #6200, and #6300, and U.S. Highway 97 to Entiat Valley Rd. #5100 or via Lucerne on Lake Chelan to Rd. #8301 - all FS roads lead to trailheads accessing the Wilderness.

MILES OF TRAIL: 450 miles

ELEVATION RANGE: From 2,000 feet to 10,541 feet on Glacier Peak

GENERAL DESCRIPTION: The Glacier Peak Wilderness is located within portions of Chelan, Snohomish, and Skagit Counties in the northern Cascade Mountains. The area is characterized by heavily forested stream courses, steep sided valleys, and dramatic glacier crowned peaks. The area contains numerous streams and many small high elevation lakes. It contains more active glaciers than any other area within the lower 48 states. Glacier Peak, a dormant volcano, is the dominant geologic feature. Forest vegetation is comprised of true firs, spruce, and hemlock, as well as stands of pine on eastern slopes. Various species of wildlife inhabit the area and include deer, elk, bear, mountain goat, marten, and lynx. Grouse are found throughout the area, and the primary fishery is cutthroat trout. Other species include eastern brook, german brown, rainbow and bull trout; and sockeye, steelhead, and chinook salmon. At Twin Lakes, the State Department of Wildlife operates a cutthroat trout egg breeding area, the only one in the State.

Glacier Peak is a heavily used Wilderness. Lyman Lakes receives considerable use from visitors at Holden Village, a church camp in the Railroad Creek drainage. Spider Meadow is a popular

area. Buck Creek Pass near Glacier Peak is a heavily used area. Indian Creek and White River trails provide access to the Pacific Crest National Scenic Trail (PCNST). There are also several mountain climbing routes on Glacier Peak that begin at White Pass.

c. HENRY M. JACKSON

LOCATION: Mt. Baker-Snoqualmie and Wenatchee National Forests, Darrington, Skykomish, and Lake Wenatchee Ranger Districts

SIZE: 103,591 acres

KEY ACCESS POINTS:

1. East of Granite Falls to Mt. Loop Hwy. via Barlow Pass and the North Fork of Sloan Creek to Trail #648, the Cougar Lake Trail.
2. Stevens Pass. Pacific Crest Trail 2 miles north to Wilderness.
3. Northeast from the town of Index, North Fork Skykomish River Road #63. All trails north of Garland Mineral Springs.
4. U.S. Highway 2 to Smithbrook/Rainy Creek Road #6700 to access the southern portion; U.S. Highway 2 to State Highway 207 to Little Wenatchee Road #6500 and Heather Lake Trailhead Road #6701 400 in the northern portion. Main trail access is via Little Wenatchee Trail #1525, Cady Creek Trail #1501 and Cady Ridge Trail #1532.

MILES OF TRAIL: 49 miles

ELEVATION RANGE: 2,350 to 7,835 feet (Sloan Peak)

GENERAL DESCRIPTION: The Henry M. Jackson Wilderness is located within Snohomish, King, and Chelan Counties. This area is adjacent to the existing Glacier Peak Wilderness. Streams in the northern portion of this area drain into the Sauk River, while the southern portion is drained by the Skykomish River. The southern portion lies adjacent to the Old Cascade Tunnel and

WILDERNESS

Nason Creek. The vegetation includes cedar, Douglas-fir, true firs, spruce, western and mountain hemlock, and at higher elevation, alpine meadows. The area supports cougar, mountain goat, marten, lynx and hoary marmot. Deer is the major big game species. Blue grouse also inhabit the area. Cutthroat trout is the main fishery.

The terrain is rugged, with steep slopes and finger ridges dissected by small intermittent or permanent drainages. Main features of the area include Cady Creek and upper Little Wenatchee River. The Pacific Crest National Scenic Trail (PCNST) traverses the south portion of the Wilderness. The area is rich in mining history with approximately 900 acres of patented mining claims within the Wilderness. This area contains approximately 30 lakes which receive moderate use for fishing as well as use by horseback riders.

This is a heavily used Wilderness north of Stevens Pass. It contains a popular portion of the PCNST and easy day hike attractions such as Lake Valhalla and Lake Janus. Popular horseback and hiker destinations are Top and Pear Lakes and the Little Wenatchee, Cady Creek, and Cady Ridge Loop trail system. Other attractions include Fortune Pond, Lake Sally Ann, Heather Lake, and scenic Grizzly Peak.

d. ALPINE LAKES

LOCATION: Wenatchee and Mt. Baker-Snoqualmie National Forests; Lake Wenatchee, Leavenworth, Cle Elum, Skykomish, and North Bend Ranger Districts

SIZE: 393,360 acres

KEY ACCESS POINTS:

1. On the east side--U.S. 2 to Icicle Road #76 and various trailheads in the Icicle Valley.

2. U.S. 97 to County Route #970 to FS Road #9737, and various trailheads in the Teanaway River drainage; or to State Route #903, to FS Road #4600 to trailheads in the Cooper River drainage; or FS Road #4330 and trailheads in the Cle Elum River Valley.

3. On the west side--U.S. 2 to Stevens Pass and PCNST access; or to FS Road #6410 and Tr. #1072.

4. Interstate 90 to Snoqualmie Pass and PCNST access; or to FS Road #6410 and Tr. #1072.

5. Interstate 90 to Snoqualmie Pass and PCNST access; or to FS Road #5630 and Tr. #1002; or to FS Road #5620 to the Waptus River Trail from the west.

MILES OF TRAIL: Approximately 800 miles

ELEVATION RANGE: 1,600 feet in the lowest valleys to 9,415 on the summit of Mt. Stuart.

GENERAL DESCRIPTION: The Alpine Lakes Wilderness lies in portions of Chelan, King, Kittitas, and Snohomish Counties between Stevens Pass and Snoqualmie Pass. It was so named because of the over 700 small mountain lakes nestled among the high rock peaks and timbered valleys of the region. Additionally, numerous rivers and streams traverse the Wilderness. Fish planting by the Washington Department of Wildlife has provided sport fishing for cutthroat and rainbow trout in many of the previously barren high lakes.

Wildlife species represented include blacktailed and mule deer, elk, mountain goat, beaver, otter, weasel, mink, bobcat, badger, and bald eagle. This Wilderness is one of the most heavily visited natural areas in Washington State, with nearly half the State's population within an hour's drive of the area. Several hundred miles of recreation trail traverses the Wilderness.

This is one of the most popular and heavily visited Wilderness in the Cascade Mountain Range, as well as the United States. The unique Enchantment Area is a major attraction. Other popular areas are: Frosty Pass; Icicle Ridge; and Eightmile, Stuart, Spectacle, and Waptus Lakes. Fishing and rock climbing are also popular. The Pacific Crest National Scenic Trail traverses the Wilderness from Snoqualmie Pass to Stevens Pass.

e. NORSE PEAK

LOCATION: Mt. Baker-Snoqualmie and Wenatchee National Forests; White River and Naches Ranger Districts

SIZE: 50,923 acres

KEY ACCESS POINTS:

1. Highway 410 to Crystal Mt. turnoff. Four miles to Norse Peak Trailhead #953.
2. Highway 410 to FS Rd. #7174 to road end at Corral Pass. Trail numbers 1155 and 1184.
3. Greenriver Rd. to Hines Camp. Greenwater River Trail #1175.
4. Highway 410 to Tr. #953; and FS Rd. #1902 to Tr. #951.

MILES OF TRAIL: 52 miles

ELEVATION RANGE: 3,200 to 6,858 on Norse Peak.

GENERAL DESCRIPTION: The Norse Peak Wilderness is located in northeastern Pierce County and northwestern Yakima County. The area straddles the Cascade Crest between Chinook and Naches Pass. Topography is generally high and steep with rocky terrain at the high elevations; narrow valleys, mountain lakes, and open park-like basins. Vegetation includes Douglas-fir, true firs, western and mountain hemlock, ponderosa and white pine, Englemann spruce, as well as some lodgepole pine, larch, and Alaskan and red cedar. A variety of wildlife inhabits the area including mule and blacktail deer, elk, black bear, mountain goat, Canada lynx, cougar, fisher, and wolverine. Game birds include spruce, ruffed, and blue grouse. Cutthroat, rainbow, and eastern brook trout are found in area waters. Some deposits of placer gold at the heads of Morse and Crow Creeks are of interest to recreational miners. A notable attraction is Fife's Peak which is a remnant volcanic cone. Norse Peak is a prominent feature.

This is a moderately used Wilderness. Major attractions are Lake Basin, and Shepherd and Crow Creek Lakes.

f. WILLIAM O. DOUGLAS

LOCATION: Wenatchee and Gifford Pinchot National Forests; Naches and Packwood Ranger Districts

SIZE: 167,195 acres

KEY ACCESS POINTS: Highway 410 parallels the northern boundary of the unit providing access to Road #1800 395 and #1800 and trailheads such as Kettle Creek Trail #957; from Highway 410, access is possible to American Ridge Trail #958 in the Bumping Lake vicinity; and Highway 12 accesses Roads #1500, #1306, and #1308 in the Rimrock area.

MILES OF TRAIL: Approximately 250 miles

ELEVATION RANGE: From about 3,200 feet in the valley bottoms to 7,766 feet on Mt. Aix.

GENERAL DESCRIPTION: This area is characterized by forest vegetation types such as mountain hemlock, alpine and subalpine fir, western hemlock, grand fir, Douglas-fir, and ponderosa pine. Topography includes scattered peaks, sharp ridges, and steep slopes. In contrast, Tuma Plateau, south of the Cougar Lakes vicinity appears flat. There are also areas of gently sloping topography with numerous natural openings of various sizes. Hundreds of small lakes and potholes are scattered throughout the area. Many high lakes are stocked with trout. Major big game species are found in the area, as well as mountain goats. Cougar, Canada lynx, Cascade red fox, fisher, and wolverine have been known to inhabit the area. Blue grouse, and ruffed grouse are among the game birds in the area. Notable topographic features include American Ridge on the north and the Cascade Mountain Crest. To the east, Nelson Ridge contains several major peaks which include Mt. Aix, Bismarck, Shellrock, and Rattlesnake. The tributaries of four major river drainages lie within the area and include the American, Bumping, Little Naches, and Tieton Rivers. A variety of recreation use is available, and a portion of the Pacific Crest National Scenic Trail (PCNST) serves the area.

Main features of this moderately visited Wilderness include popular day use areas such as Dewey Lake and Twin Sisters Lakes. Other popular

WILDERNESS

areas are Cougar, Fish, Apple, Pear, and the Tumac Plateau Lakes. The PCNST traverses the length of the Wilderness from White Pass to Chinook Pass.

g. GOAT ROCKS

LOCATION: Wenatchee and Gifford Pinchot National Forests; Naches and Packwood Ranger Districts

SIZE: 22,953 acres of additions
82,680 acres original area
105,633 acres total Wilderness

KEY ACCESS POINTS: Highway 12 to FS Rds. #1000, and #1207, and PCT #2000 and other trailheads from the north; I-5 to Highway 12 to FS Rds. #1114 and #1104 from the southwest.

MILES OF TRAIL: Approximately 120 miles

ELEVATION RANGE: From 3,000 feet in river valley bottoms to 8,200 feet on Gilbert Peak.

GENERAL DESCRIPTION: The Goat Rocks Wilderness is located in portions of both Yakima and Lewis Counties, generally between Mt. Rainier and Mt. Adams. The area is bounded by U.S. Highway 12 and the White Pass Ski area on the north and the Yakima Indian Reservation on the southeast. The Tieton and Klickitat River systems drain the east side of the Wilderness, and streams of the Cowlitz River system feed from the west side. Vegetation types consist of true firs and hemlocks as well as some Alaska yellow cedar and western white pine. The alpine soils are shallow and rocky. A recent influence on these soils was the May 1980 eruption of Mount St. Helens which deposited a layer of ash on the area which was several inches thick in places. Wildlife populations include deer, elk, coyotes, bear, pika, northern three-toed woodpecker, and marten. Mountain goats may be sighted within the area. Game birds such as blue, ruffed, and spruce grouse are also present. Streams and lakes support cutthroat and rainbow trout. Dolly Varden trout inhabit the North Fork of the Tieton River. The Pacific Crest National Scenic Trail, traverses the Wilderness from north to south.

This moderately used wilderness attracts visitors to popular McCall Basin via the PCNST. Visitors can also ride the White Pass Ski area chair lift to access Shoe Lake and the PCNST easily.

7. WILDLIFE

a. Overview

The Wenatchee National Forest provides year-round or seasonal habitat for an estimated 394 species of wildlife, which includes 13 amphibians, 18 reptiles, 273 birds, and 90 mammals.

The wide variety and number of wildlife species is due to the diversity of habitat found on the Forest: from high elevation habitat suitable for mountain goats, to low elevation habitat suitable for jack rabbits. There is wet, westside type habitat used by spotted owls and dry eastside habitat with mule deer. These extremes of habitat and the habitat in between often occur close together with the result being a large patchwork of vegetation types. Fire also plays a role in providing a range of successional stages of diverse tree types.

b. Proposed, Endangered, and Threatened Species

Proposed, endangered, and threatened wildlife species found on the Forest are the bald eagle, peregrine falcon, grizzly bear, gray wolf, and northern spotted owl.

1. Bald Eagle

Nesting habitat for the bald eagle consists of large, dominant or codominant trees in a heterogeneous stand of mature or old-growth coniferous timber. Bald eagles utilize additional nests within their territory. Nesting habitat is generally within 1/2 mile of feeding habitat which is composed of open areas having a wide field of view (Brown et al., 1985). Feeding habitat is almost always rivers and lakes where fish, waterfowl and other species are preyed upon.

Roosting habitat are areas where eagles spend the night, use some time during the day, and use in severe weather conditions. Roost areas have clear lines of sight to surrounding terrain, favorable microclimates, stout perches high above the ground, and have limited human activity nearby. Roost trees are larger than average in size and tend to be located in mature or old-growth conifer stands. These sites may be as far as 9 miles from the feeding habitat (Brown et al, 1985).

The tallest trees, on the edge of stands, with strong lateral branches high in the crown (often a snag), make up the perching habitat (Brown, et al., 1985). Perching habitat is usually within or close to the edge of the feeding habitat. This habitat is where bald eagles may spend as much as 90% of their time.

Bald eagles winter in areas with open waterways or areas where sources of carrion are available and communal perch and roost trees are close by.

Although populations are lower now than 50-100 years ago, they have increased in the last 5 years. The Wenatchee National Forest currently has one nest site which was established in 1985, and two more suspected nest sites were reported in 1988. The existing nest site is being protected. The suspected sites will be surveyed to determine if nests do exist.

The Forest has 241 lakes with approximately 50,000 surface acres of water and 1,149 miles of streams and river receiving fish and waterfowl use. There are thousands of acres of mature and old-growth stands available for bald eagle nesting within one mile of the potential feeding habitat. Nesting and feeding habitat appear to be plentiful on the Forest. Therefore, the limiting factors may be lack of adult eagles, activity of people, or lack of perching habitat near feeding areas.

2. Peregrine Falcon

The nesting habitat for the peregrine falcon is characterized by rocky cliffs or bluffs, often overlooking rivers and lakes. However, there may be up to 10 miles between the nest and feeding habitat. Feeding habitat includes marshes, lakes,

and rivers, as well as upland, open habitats where there is an abundance of song birds, shorebirds and waterfowl (Welty, 1975).

Historically, the peregrine falcon nested on the Forest and throughout central Washington. Single birds have been reported flying or feeding between August and October each year, but no active nest sites have been found (Peregrine Falcon Survey, Washington Department of Wildlife, 1987). The Washington Department of Wildlife (WDW) has inventoried part of the cliffs, bluffs, and rock outcrops on the Forest and rated them for nesting. This survey shows there are at least 10 potential sites where falcons could nest in the future.

Peregrine falcons are very sensitive to human disturbance near nest areas between April to June (Sackett, 1989). Habitat can be affected by timber harvesting, road and trail construction, and recreation activity.

3. Grizzly Bear

Grizzly bear dening habitat consists of boulders, logs, caves, or soils deep enough for digging a den in a setting that is steep, high in elevation, and near timberline.

Because grizzly bears are omnivorous, their forage species and foraging areas change with the season. Feeding habitat is made up of generally small, interspersed openings in close proximity to cover for hiding and isolation from human disturbance. Late winter and early spring habitat includes deer or elk winter ranges, avalanche chutes, riparian areas, and meadows. Summer habitat includes meadows and shrub areas where deer fawning may occur, as well as rivers and riparian areas when salmon are spawning. Berry shrub fields make up their fall habitat.

Historically, the grizzly bear was found throughout the Forest. Although there have been recent sightings in a number of areas on the Forest, no dens have been located (Historical and Recent Grizzly Bear sightings in the North Cascades, J. Bjorklund, 1980). Portions of the Forest are included in the North Cascades Grizzly Bear Ecosystem, which is currently being studied as part of an interagency effort to determine if grizzly bear populations will be restored here.

4. Gray Wolf

Dening habitat of the gray wolf is located in remote country on high ground near sources of water. The dens are occupied for only a two month period for birth and care of the young (WDW Sackett, 1988). The wolf's feeding habitat occurs in remote areas having an abundance of big game and small mammals. Feeding occurs in a variety of habitats and shifts as the locations of the prey populations shift.

Human activities have had serious impacts to wolf populations through exploitation, habitat reduction, and population control. (Northern Rocky Mountain Wolf Recovery Plan, 1987) Historically, the gray wolf was found throughout the Forest and there have been a few sightings on the Forest (WDW data base on wildlife sightings).

There is no direction at the present time to provide habitat for the gray wolf.

5. Northern Spotted Owl

The status of the northern spotted owl changed between the Draft and Final EIS. In the Draft, the spotted owl was listed as a Region Six sensitive species. On June 23, 1989, the U.S. Fish and Wildlife Service (USFWS) issued a ruling that proposed the listing of the northern spotted owl as a Federal threatened species pursuant to the Endangered Species Act (as amended) of 1973.

In addition to the ruling by USFWS, the Forest Service issued a Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide (SEIS) in July 1988. The SEIS established specific direction for the management of northern spotted owl habitat areas to be used in Forest planning.

The northern spotted owl is a species that typically depends on mature or old-growth forest stands for nesting and feeding. The old-growth habitat requirements for spotted owls have been described in the SEIS. For the Wenatchee National Forest, these requirements include:

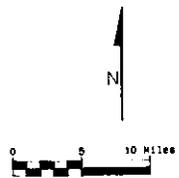

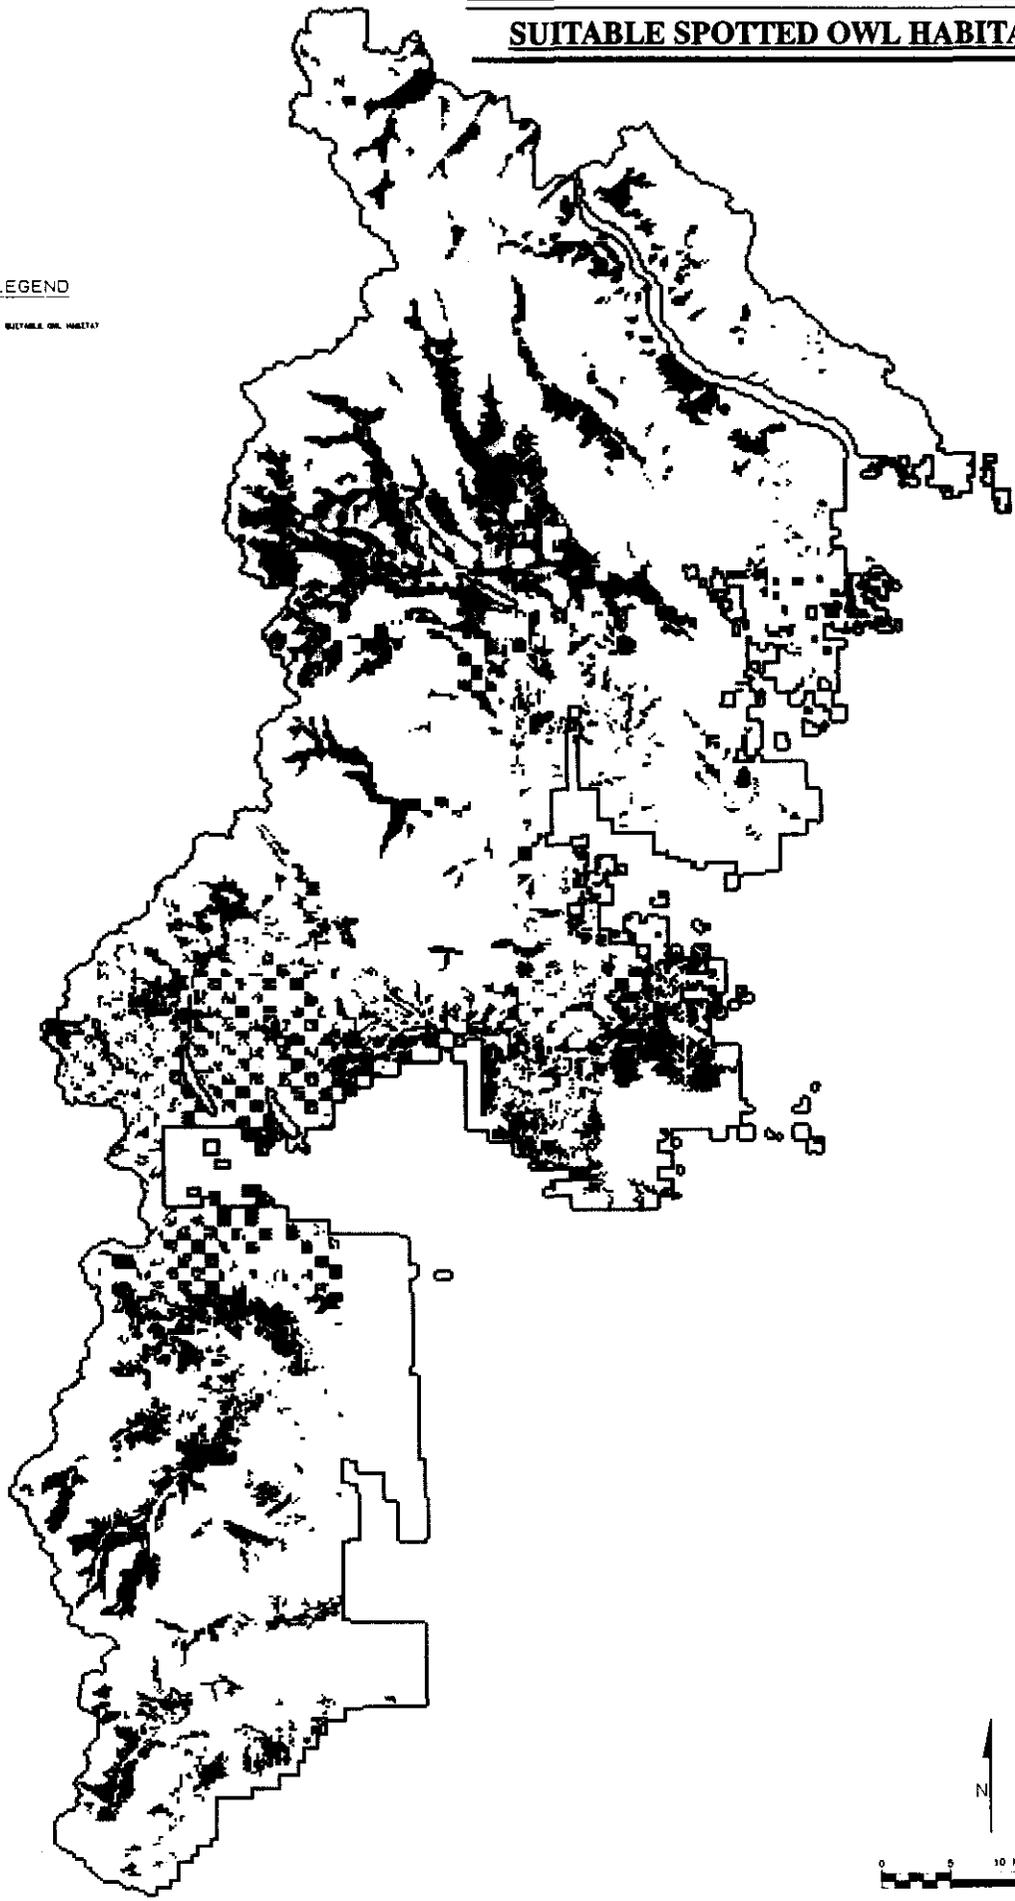

- a. Mature to old stands of conifer trees characterized by cavities caused by disease and mechanical damage, and platforms created by mistletoe and/or goshawk nests. Generally the stands are a mix of Douglas-fir, western red cedar, grand fir, spruce, lodgepole pine and ponderosa pine.
- b. The stands have an uneven-aged multi-layered canopy. There may be an overstory of 100-400 year old trees; an understory of mature to pole sized trees which are 50-150 years old; and a sapling/trees/shrub layer 10-50 years old.
- c. Overstory canopy closure may be as low as 40%, but is usually 60% or greater.
- d. Owls prefer the larger diameter trees in an area. These may be the older trees, with the dominant ones usually 20 inches in diameter or larger, but there are occasions when the dominant trees may be as small as 12-14 inches in diameter.
- e. Dead standing trees reflect the diameter of the stand. Due to the low site potential and because the non-dominant trees die first, most of the dead trees are less than 20 inches in diameter. Dead standing trees are abundant, with an estimated 10-50 per acre.
- f. Fallen trees and decayed logs are abundant and often small in diameter.

The above definition of habitat applies to nesting areas and spring, summer and fall roosting areas. The winter habitat needs of the spotted owl are not known. The size of habitat areas for spotted owls on the Forest has been determined to be 2,200 acres (SEIS).

SUITABLE SPOTTED OWL HABITAT MAP

LEGEND

 SUITABLE OWL HABITAT

The Forest is currently collecting timber and stand structure information from stands with known spotted owl nest trees as a result of its Memorandum of Understanding with National Council of Paper Industry for Air and Stream Improvement (NCASI). The Pacific Northwest Experiment Station of the Forest Service has begun a research project to determine more specifically the habitat needs and home range of the spotted owl.

As of 1988, suitable spotted owl habitat on the Wenatchee National Forest was estimated to be 519,000 acres. From 40 to 70% of these acres have dominant trees larger than 20 inches in diameter. Another 149,000 acres of the total is located in wilderness areas. The estimates of suitable habitat are continually being refined as biologists learn more about spotted owl habitat needs and visit sites to verify habitat suitability.

By the end of 1988, 139 spotted owl sites had been located on the Forest. During the past five years, 36 sites had nesting birds, 19 contained a pair of spotted owls, 72 had single spotted owls, and 12 sites had negative responses. Young owls have been produced in at least 11 of the last 12 years on the Forest. Most of the nest sites are platforms of mistletoe; up to 1/3 of which were former goshawk nests. As more inventories and monitoring is completed, it is expected that more active nest sites and pairs will be found.

Many of the sites containing spotted owls have goshawks nearby. There are also many great horned owls, barred owls, and a few great gray owls on the Forest. These species compete with spotted owls for habitat and prey species; they also have been known to prey upon spotted owls when opportunities arise.

Spotted owls prey mostly upon flying squirrels and other small mammals. Many of these mammals require standing dead or down woody habitat during some part of their life cycle.

Spotted owls are found on the most northerly, southerly, and western parts of the Forest. They are not generally found in pure ponderosa pine stands, alpine fir, large stands of lodgepole pine, or grass/shrub habitat.

c. Sensitive Species

Wildlife species listed as sensitive by the Regional Forester and found on the Forest include: big-horn sheep, Townsend's big-eared bat, Canadian lynx, California wolverine, ferruginous hawk, Swainson's hawk, and the long-billed curlew.

1. Bighorn Sheep

Bighorn sheep live in steep, open, dry grass/shrub habitats generally below 4,000 feet in elevation. Their winter range is composed of south facing, open slopes with nearby forests for cover (Johnson, 1983). This habitat overlaps with the lower elevation deer winter ranges. Three populations are known to use the east edge of the Forest.

Bighorn sheep were found throughout eastern Washington before settlement by the white man. They were eliminated from the Forest between 1900 and 1940. Re-introductions occurred to former ranges in the 1960's and 1970's. Diseases from domestic sheep and poaching are the two factors that appear to keep the populations at a low level.

Some information on habitat inventories and locations of habitat for bighorn sheep is available from the Washington Department of Wildlife (WDW). Management plans for this species need to be developed in coordination with the WDW.

2. Townsend's Big Eared Bat

Roosting and reproductive habitat for the Townsend's big eared bat is composed of caves, mine shafts, and buildings, with adjacent forest for thermal cover (Humphrey and Kunz, 1976).

This bat lives communally in a cave that is used year after year by the same population. In the spring and summer, nursery colonies are used to raise young. Feeding habitat has not been defined, but water near or within the feeding area is essential. The bats feed primarily on insects. They are sensitive to human disturbance and will abandon sites when disturbed (WDW Species Status Summary, 1987).

Boulder Cave on the Naches Ranger District is the only known site on the Forest where these bats are known to exist.

There are many rock cliffs on and adjacent to the Forest containing caves that may be used by this bat. Only a few scattered population inventories and samples have been completed on the Forest.

3. Canadian Lynx

The habitat for lynx occurs in high elevation areas dominated by lodgepole pine and spruce/sub-alpine fir forests. They hunt in thickets, feeding mostly on snowshoe hare and tree squirrels, and den in mature and old growth stands with a high number of down trees. Since the Wenatchee has few large areas of lodgepole pine stands, it appears most of the lynx use some other habitat.

Lynx have been trapped or seen on the Forest for many years. Sightings are uncommon, the most recent being on the Cle Elum Ranger District in 1987.

The effects of timber harvesting and recreation activities on the lynx are not understood. More specific information on habitat and distribution of Canadian lynx on the Wenatchee National Forest is needed.

4. California Wolverine

The California wolverine utilizes a variety of habitats over extensive, remote areas. The wolverine is a resident of boreal forests and is particularly fond of marshy areas. They den in rocks, under wind-thrown trees and under the snow. While this species has been sighted on the Forest, there have not been inventories of habitats or populations. This species is heavily impacted by man-caused disturbances and habitat alterations. The population levels and habitat requirements for wolverine are unknown at this time.

5. Ferruginous Hawk

Nesting habitat for the ferruginous hawk consists of tall trees along streams and on cliffs or rocky pinnacles. The feeding habitat is made up of

grasslands, shrublands, and open timber stands. The ferruginous hawk preys upon rabbits, gophers, mice, bats, snakes, lizards, and grouse.

Ferruginous hawks are occasionally sighted on the Forest; the latest sighting was in the Taneum Ridge area in the fall of 1988. The habitat for this species is found on the east edge of the Forest in the drier more open habitats. There is little known about the populations and distribution of this species on the Forest. Timber harvesting and road construction could affect this bird by altering habitats and the prey base.

6. Swainson's Hawk

Swainson's hawk nesting habitat consists of trees in open timber stands or scattered trees in non-forested areas. They also have been known to nest on cutbanks or low cliffs. The Swainson's hawk forages for prey in open fields, grassland, or open stands of trees. It feeds primarily on insects, mice, or bats.

Occasional sightings of this hawk have occurred on the Forest. Habitat for the Swainson's hawk is found on the east edge of the Forest in the drier sites of open ponderosa pine and Douglas-fir. The Forest has no inventory of this species or its habitat. Management activities that could affect the Swainson's hawk include timber management, livestock grazing, and road construction.

7. Long-billed Curlew

The nesting habitat for the long-billed curlew occurs in moist or dry meadows. Their feeding habitat is grasslands, uplands, ponds, marshes, lakes, and rivers. Curlews feed on insects, crayfish, berries, and snails.

While the long-billed curlew could potentially be found in a number of locations on the Forest, a limited amount of habitat is available. Few sightings have been reported on the Forest. The Forest has no inventory information of populations or habitats of this species. Livestock grazing and recreation activities in summer, spring, and fall could have some effects on this bird. Road and trail construction through habitat used by the long-billed curlew could adversely affect it.

d. Management Indicator Species

Management Indicator Species (MIS) are plant or animal species whose population characteristics (presence, number, density, sex ratio, age structure, recruitment, mortality rates, and distribution) can be used to evaluate the effects of land and resource management practices on the habitats they use. Indicator species management is a wildlife management strategy designed to monitor environmental changes.

In selection of the MIS, the following categories will be represented where appropriate:

1. Endangered and threatened species;
2. Species with special habitat needs that may be influenced significantly by planned management programs,
3. Species commonly hunted, fished or trapped, non-game species of special interest; and
4. Species whose population changes are believed to indicate the effects of management activities on other species of major biological communities (CFR 219.19).

**TABLE III-12
WILDLIFE MANAGEMENT
INDICATOR SPECIES
AND THE HABITATS THEY REPRESENT**

Species	Habitat
Northern Spotted Owl	Mature or old-growth coniferous habitat
Pileated Woodpecker	Mature or old-growth coniferous habitat
Marten/Northern Three-Toed Woodpecker	Mature or old-growth coniferous habitat
Mountain Goat	Rockland, alpine, high elevation old growth conifer habitat
Mule Deer	Shrub, grass, meadow, thermal and hiding cover
Rocky Mountain Elk	Shrub, grass, meadow, thermal and hiding cover
Primary Cavity Excavators	Standing and down dead and defective trees
Beaver/Ruffed Grouse	Riparian/deciduous habitat

1. Mature and Old Growth Coniferous Habitat

Spotted owls, pileated woodpeckers, marten, and northern three-toed woodpeckers were selected as management indicator species on the Forest to maintain distribution and viability of all wildlife species dependant upon mature/old growth conifer habitat. The requirements for marten and northern three-toed woodpeckers are combined This was because it appears both species requirements can be met while reducing the complexity of their management on the Forest. For more information, see Appendix I.

a). Northern Spotted Owl

For further information on the spotted owl, see the previous discussions above and the management requirements analysis in Appendix I.

b). Pileated Woodpecker

The nesting and roosting habitat of the pileated woodpecker is a cavity in a large, dead tree in a shaded place, usually near valley bottoms, and often near water. Each woodpecker excavates 1-3 cavities per year for nesting or roosting purposes. Their feeding habitat consists of rotten standing trees, rotten logs, live trees with rot and rotten stumps. Pileated woodpeckers feed mostly on ants and wood-boring beetles.

The nesting and feeding habitats are found in mature or old-growth conifer stands which are often in riparian areas. On the Wenatchee, this habitat is found throughout forested areas below about the 5,000 foot elevation level. The pileated woodpecker is rarely seen in the Forest, but signs of their feeding activities can often be found.

Harvesting of dead trees, mature trees, and old-growth trees reduces or eliminates suitable habitat for the pileated woodpecker and the species it represents. There are no inventories of populations or suitable habitat on the Forest for this woodpecker. The State of Washington lists the populations of the pileated woodpecker as being on a decline (Species Status Summary, WDW, 1987).

c). Marten

Denning habitat for the marten consists of holes in snags, hollow logs, and burrows under trees and large rocks. Due to its size, large snags or down trees are required. The marten's feeding habitat occurs near a food source on the ground or in the trees. Their prey may be mammals, reptiles, fish, insects or berries.

The marten requires habitat with sufficient cover, using tree canopy for security and cavities in trees for resting. Mature or old-growth conifer stands throughout the Forest, with the exception of pure ponderosa pine stands, may provide suitable

habitat if a prey base is available. The harvest of dead, mature, and old-growth trees reduces or eliminates suitable habitat.

Pine marten are occasionally sighted and are also trapped on the Forest. The Forest has no inventories of populations or suitable habitat for the pine marten. Information is available for the locations and numbers of pine marten that have been trapped on the Forest from the Washington State Department of Wildlife. A study of the marten was also done on the Forest (Newby, 1951). The State of Washington lists the populations of this species as declining (Species Status Summary, WDW, 1987).

d). Northern Three-Toed Woodpecker

The nesting habitat for the northern three-toed woodpecker is a cavity in a dead tree within a clump of dead trees located near live conifers. Its feeding habitat is dead or living mature and old-growth trees, where prey are obtained from under the bark. The prey are most commonly beetles and wood-boring larvae.

This species is often seen or heard throughout the conifer habitat of the Forest. No inventories of populations or suitable habitat have been completed.

e). Mountain Goats

Mountain goats were selected as a management indicator species because the present population is divided into a number of sub-populations where management activities, or the lack of them, could potentially eliminate a sub-population and thus reduce distribution. The potential also exists for losing a viable population because a given population may be small.

The rearing habitat for mountain goats is south or east facing slopes, with a good mixture of boulder fields or rocky outcrops and forage areas. Free-flowing water should be within 1/2 mile of kidding grounds (Johnson, 1983). Their feeding habitat is open, shrubby areas and meadows in spring, summer and fall. Escape cover is provided by cliffs, rimrock and talus slopes and is a critical year-round habitat component.

Winter habitat for mountain goats is a limiting factor. It consists of relatively snow-free south or east-facing slopes below timberline, or wind swept ridges above timberline. Mature and old growth forest stands are preferred as optimum thermal cover; however, this habitat component is not always available. Preferred foods for mountain goats are shrubs, mosses, and lichens within the stands of trees.

Increased use of an area in or adjacent to mountain goat habitat, by either recreation or management activities, can result in reduced mountain goat use in the area. The disturbance of escape cover is especially a problem during the kidding season (May 15 - June 15).

The Washington Department of Wildlife manages mountain goat areas on the Forest for either viewing or hunting, and has transplanted mountain goats from other locations in Washington to several locations on the Forest.

The Wenatchee National Forest maintains a population of 1,600 goats, which is a large part of the mountain goat population within Washington State. Mountain goats are found in small populations scattered across the Forest; the majority of their habitat is located within wilderness areas. Mortality within the population is high due to natural causes.

f). Mule Deer

The mule deer was selected as a management indicator species because of the demand for it as a big game species. The mule deer is an MIS for bighorn sheep habitat and for species requiring early successional habitat needs.

Rearing habitat for mule deer requires high quality forage within 600 feet of water with nearby hiding cover (Thomas, 1979). Their feeding habitat consists of high quality summer forage, which provides a large part of the energy needed for winter survival. On spring ranges, mule deer need forage with a high protein value to help recuperate from the stress of winter.

Cover requirements on winter ranges is an important habitat component; thermal cover can reduce the amount of energy lost during periods of extreme cold.

The Wenatchee National Forest has an abundance of summer range for mule deer, but a limited amount of winter and spring range. There is an estimated 106,000 acres of winter range on the Forest. As winter range off the Forest is developed for recreation, agriculture, residential or other commercial uses, the winter range on the Forest will receive increased importance in maintaining deer herds.

It is estimated that the summer range on the Forest maintains 20,000 to 25,000 deer on a estimated 1,500,000 acres. The number of deer maintained on the winter range managed by the Forest is about 10,000.

The Wenatchee National Forest, in cooperation with the Washington Department of Wildlife, Chelan County Public Utility District, and other interested groups, has made improvements to deer winter range.

The Washington Department of Wildlife would like to emphasize management for mule deer rather than elk north of Highway 2 because the conflicts between orchards and deer would be much less than those for elk. The Forest Service and Washington State Department of Wildlife both have significant acreages of winter range and will continue to coordinate activities that affect deer winter range.

Management activities that affect mule deer and mule deer habitat include timber harvest which modifies the arrangement of habitat components; livestock grazing which can affect the availability of forage and browse; road construction and use which eliminates habitat and can reduce animal use in adjacent areas; and mining operations which can eliminate habitat and reduce use in adjacent areas. The activities which have the most pronounced effect on mule deer are the use of roads and the removal of thermal cover in areas where cover is limiting.

Deer populations can be adversely affected when activities such as timber harvest, livestock grazing, mineral exploration, and winter recreation are active on the winter and spring ranges while the deer are present.

Hunting and viewing of deer are major recreation pursuits. Many areas of summer range receive only limited hunting pressure due to limited access and rough terrain. Some people like to view deer in the winter and spring. Winter range access is accomplished via includes four-wheel-drive vehicles, snow machines, skis, or by walking. Disturbance on winter and spring ranges causes deer to use energy needed for survival. The loss of energy at this time may adversely affect survival and/or production of young.

g). Rocky Mountain Elk

The Rocky Mountain elk was selected as a management indicator species because of its importance as a big game species. Management activities that affect elk and elk habitat are timber harvest which modifies the arrangement of habitat components; livestock grazing which can affect the availability of forage and browse, road construction and use which eliminates habitat and can reduce animal use in adjacent areas; and mining operations which can eliminate habitat and reduce use in adjacent areas. The activities which have the most pronounced effect on Rocky Mountain elk are the use of roads and the removal of thermal cover in areas where cover is limiting. While these activities and effects are similar to those for mule deer, they tend to have more impact on elk. Rocky Mountain elk are more sensitive to changes in habitat condition than mule deer.

Rearing habitat for elk consists of high quality forage areas with slopes less than 15% and hiding cover nearby, within 1000 feet of water (Thomas, 1979). Preferred feeding areas have high quality forage with hiding cover nearby and little human disturbance.

Hunting and poaching activities have conditioned elk to avoid humans and vehicles. Roads and trails can increase access by people to feeding areas. The results of human disturbance can significantly reduce or prevent the use of high quality forage areas by elk.

Elk need cover habitat for escape, hiding, and resting. Optimal thermal cover is most important at higher elevations during the winter. At low elevations, shrubs and topography may provide sufficient thermal cover. At mid-elevations, elk may need 30% of an area in forest stands providing thermal cover. Each winter range area has its own habitat characteristics, depending upon those characteristics and elk population goals, the winter ranges will have differing management objectives.

The Forest and the Washington Department of Wildlife have agreements to close some roads during the hunting season to increase the quality of hunting, or provide "fair chase." Because the cost of administering these closures is high, WDW would like to see road closures year-round rather than seasonally. This would significantly reduce the road densities and increase the overall habitat effectiveness for big game.

The WDW has established management objectives that maintain or increase elk populations south of U.S. Highway 2, but reduce populations north of the highway. The purpose of the management strategy north of U.S. Highway 2 is to avoid damage to orchards from wintering elk.

A portion of the winter range on the Forest has wintering elk; however, the actual area of use has not been calculated. Elk winter at relatively high elevations (e.g. Rimrock and Bumping Lakes) but the Forest has not inventoried these high elevation winter ranges. As winter range off the Forest is developed for uses that conflict with elk, there will be increasing demand to maintain elk herds. In order to increase the number of wintering elk and prevent the elk from impacting private lands, the WDW has established several feeding areas for elk near the Forest. WDW feeds an estimated 15 to 30 percent of the elk wintering near the Forest.

An estimated 12,500 elk are summering on the Forest and use about 750,000 acres. The number wintering on the Forest is about 5,600. The large majority of the elk are hunted for bulls, with some level of cow hunting conducted to minimize problems or control herd numbers. This hunting strategy provides 60-80 hunter days per harvested animal.

The Washington Department of Wildlife owns and manages the Colockum winter range which is adjacent to the Forest. The Colockum winter range has the capability to support a larger herd of wintering elk than it does now, however, the herd size is limited by the availability of summer range. About 3,000 elk summer on the Forest, yet winter in the Colockum range. Livestock grazing can reduce the availability of forage in the Colockum area of the Forest. The Forest Service, WDW, and the Rocky Mountain Elk Foundation are cooperatively funding a study in this area. The situation is the opposite of the problems elk have in other areas where winter range is the limiting factor.

Roads and trails in key elk foraging habitat affect the amount of use a foraging area will receive. Access by humans is believed to be the most significant adverse effect on elk numbers on the Forest. Livestock grazing and timber harvesting can be beneficial to elk, or can decrease elk habitat depending on the changes in habitat effectiveness and the timing of the activity.

The Forest has some mid-to high-elevation elk wintering areas where timber harvest has reduced the optimal thermal cover component to a level where the habitat effectiveness value is below that desired for elk management. The demand for elk hunting on the Forest is very high. Due to overcrowding in some areas, the WDW has established split hunting seasons and other regulations to reduce the hunting pressure and improve the quality of the hunting experience.

h). Primary Cavity Excavators

Primary cavity excavators were selected as management indicator species to represent species dependant upon dead and down tree habitats. This habitat is being reduced in amount and distribution by management activities.

Nesting and roosting habitat for the birds are cavities in dead or defective trees. Their feeding habitat consists of rotten standing trees, rotten logs, live trees with rot, and live trees with highly furrowed and rough bark.

Because this indicator is a group of species, the habitat is throughout the forested area in all successional stages. This group uses dead trees in all stages of decay.

There are about 1,451,100 acres of the Forest that are capable of providing habitat for species dependent upon dead and defective trees. Of this total, about 807,200 acres of the capable habitat have no plans for timber management. Therefore, 55% of the dead and defective tree habitat on the Forest will be in a natural or near natural condition. The problem with management of the primary cavity excavators is not in maintaining the amount of habitat for viability, but in maintaining the distribution and quantity of habitat to provide other benefits.

Fuel management personnel have quantified the amount of down material in many parts of the Forest. This information is available for use by biologists for predicting habitat but is seldom used. There are no inventories of populations or maps of suitable habitat but there is a survey of the number of snags by decay class in unlogged stands. This survey has not been analyzed and the information is not available for use. There are a number of other studies and models available on primary cavity excavators but this information has not been put in a document to show the effects on the Forest.

Primary cavity excavators are insect eaters. As a result, the population of excavators has an effect on the number of insects in the forest. This in turn may affect recreationists or the use of trees for other purposes.

2. Riparian/Deciduous Habitat

a). Beaver and Ruffed Grouse

Beaver and ruffed grouse were selected as the management indicator species to represent other species that require water (e.g. ducks, water ouzel) and species that require deciduous trees (e.g. Wilson's warbler, western tanager).

The riparian area is the most heavily used habitat by wildlife; an estimated 262 species use riparian habitats on the Forest. Species groups such as primary cavity excavators will often be abundant in this habitat. Habitat characteristics of the riparian area of importance to wildlife are: natural edge effect with other plant communities, vertical habitat diversity, plant composition, travel routes, connection between similar habitats, free-flowing water, cooler temperatures in the summer and warmer microclimate in the winter.

The rearing habitat for beaver is made up of lodges or bank dens with underwater entrances. Their feeding habitat consists of deciduous trees such as aspen, cottonwood, and willow generally within 100 yards of water. Beaver cover habitat includes streams, ponds, lakes and reservoirs with water depths greater than 1 foot. To maintain beaver populations, streams must have low sediment loads and an adequate supply of deciduous woody plants.

The beaver utilizes all age classes of deciduous woody plants in and adjacent to riparian areas throughout the Forest. Most of the habitat is under-utilized because past trapping practices have limited the number of beaver. Other factors limiting habitat for the beaver include aggressive planting of conifer trees that compete with deciduous trees, the presence of roads in and adjacent to riparian areas that reduce the availability of habitat, and livestock grazing on deciduous woody plants within riparian zones.

Riparian habitat on the Forest is estimated to total 159,800 acres, or about 3% of the land base. The Forest has no inventories of populations or suitable habitat for beaver.

Ruffed grouse prefer deciduous or deciduous/conifer plant communities for nesting and roosting habitat. Preferred feeding habitats include open areas and meadows near deciduous trees where grouse eat various parts of deciduous shrubs and trees as well as insects. Winter cover is found in dense stands of conifer trees. The ruffed grouse depends on logs in deciduous or deciduous/conifer forests for drumming sites during the breeding season. There are no inventories of ruffed grouse populations or habitats on the Forest.

Management activities such as timber harvest, road construction, and livestock grazing can have both positive and negative impacts on ruffed grouse habitat. Timber harvest will often increase grouse habitat diversity in riparian areas, provided sufficient amounts of deciduous woody vegetation is left on the site. Road construction in and adjacent to riparian areas, meadows, and openings with deciduous woody vegetation can result in a direct loss of ruffed grouse habitat. Livestock grazing in riparian areas and meadows can reduce the value of those areas for wildlife for short periods of time. Reforestation with conifer trees reduces the amount of available deciduous habitat.

Grouse hunting is a popular sport on the Forest. The hunting seasons are long, but the number of birds harvested is dependent upon weather conditions and access.

It is not clear how these indicator species represent amphibians in the riparian zones where year-round water is not available. Habitat requirements for amphibians include logs and rocks in a cool environment within or near the stream channel.

e. Management Requirements

The Forest Service Region 6 wildlife guidelines for incorporating management requirements for wildlife into alternatives of the Forest Plan are:

1. Wildlife habitats shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area. For planning purposes, a viable population shall be regarded as one which has the estimated number and distribution of reproductive individuals to insure its continued existence is well distributed in the planning area. In order to insure that viable populations will be maintained, habitat must be provided to support, at least, a minimum number of reproductive individuals and that habitat must be well distributed so that those individuals can interact with others in the planning area. (36 CFR 219.19)

2. Habitat determined to be critical for threatened and endangered species shall be identified, and measures shall be prescribed to prevent the destruction or adverse modification of such habitat. (36 CFR 219.19 (a) (7)).

Table III-13 displays the list of species included under the Management Requirements.

TABLE III-13

SPECIES INCLUDED UNDER THE REGIONAL MANAGEMENT REQUIREMENTS

Wenatchee National Forest

HABITAT	SPECIES	INFORMATION REFERENCE
Mature and Old Growth	Northern Spotted Owl	FEIS, Chapter III, Wildlife
	Pileated Woodpecker	FEIS, Appendix I
	Marten	
	Northern three-toed Woodpecker	
Dead and Defective	Primary Cavity Excavators	FEIS, Chapter III, Wildlife
Riparian	To be identified by each Forest	FEIS, Chapter III, Wildlife
Threatened and Endangered Species	Bald Eagle	FEIS, Chapter III, Wildlife
	Peregrine Falcon	Wildlife
	Grizzly Bear	

f. Unique and/or Special Habitats and Species

Unique and special habitats are identified because there is a need to protect some habitats and species that are not identified as threatened, endangered, sensitive, indicator species or protected by management requirements

Species or habitat are identified into this category because the requirements for acres of habitat is so small that it is insignificant at the Forest scale, but is significant to meeting the requirements for wildlife on a specific project. They are also in this category because there is suspected to be some need for management of the species but there is so little known about the species on the Forest that no specific species management or habitat

has been identified. It is suspected that some management for these species or habitats will be developed in the future.

The unique and special species identified on the Forest at this time are great gray owl, boreal owl, barred owl, great blue heron, wild turkey, swifts, goshawks, osprey, sharp-shinned hawks, cougar, bobcats, and amphibians. The Forest has inventories for great blue heron and partial inventories of goshawks, great gray owls, and barred owls.

Furbearers provide an economic value to some individuals, but the overall value to the Forest and community is low. As a result, there is no management direction or evaluation of furbearers. The effects of timber harvest on furbearers are shown in the following table.

TABLE III-14

FURBEARERS BY EFFECTS OF TIMBER HARVEST

No Effects	Positive Effects	Negative Effects
Coyote	Bobcat	Marten
Mink	Red Fox	Wolverine
Opossum	Long Tailed	Fisher
Raccoon	Weasel	Striped Skunk
Badger		Lynx
Short-Tailed Weasel		
Nutria		
Muskrat		
River Otter		
Beaver		

g. Demand for Wildlife

Because of the Forest's location in relation to large population centers and easy access to most of the Forest, there is a large demand for wildlife viewing and hunting. The Forest was known in the past for its good deer hunting but, due to loss of winter range on private land, that reputation has declined. The elk hunting on the Forest is known throughout the state as one of the best. There are opportunities for cougar hunting, upland bird hunting, and trapping on the Forest. The number of big game hunters has decreased in the past few years due to unavailability of animals and poor quality hunting conditions. The quality of the hunt and the number of animals available for harvest can be controlled by the management of the habitat. Wildlife viewing has increased over the last decade and the trend is expected to continue.

In 1975, the U.S. Fish and Wildlife Service conducted a national study to determine the amount of wildlife use in the country. That study revealed that for every hunter there was another person using wildlife for viewing. In 1985, the study was repeated and the ratio of wildlife viewers increased to about 6.5 for every hunter. This same trend has occurred on the Forest in the last few years. More people are coming to the Forest to view wildlife now than ever before, yet to date, no plans have been made to provide areas for wildlife viewing. The problem is one of how to provide viewing of wildlife without destroying the conditions people come to see. However, many opportunities currently exist to develop areas for wildlife viewing on the Forest.

TABLE III-15

**ESTIMATED NUMBER OF WILDLIFE
USER DAYS (WFUDs)
PRODUCED FOR WILDLIFE IN 1987**

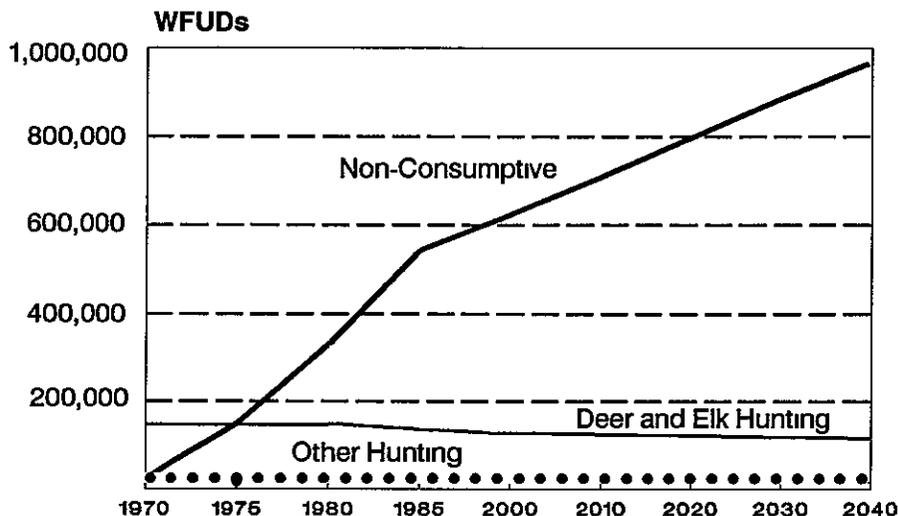

Species	Hunting	Viewing
Non-Game Species	0	971,069
Mule Deer	61,161	35,623
Rocky Mt. Elk	58,698	18,548
Grouse	9,299	0
Bear	5,041	0
Mountain Goats	221	1,911
Chukar	200	0
Quail	167	0
Cougar	163	0
Other Game Species	200	0
Total	135,150	1,027,151

TABLE III-16

VALUES OF WFUDs IN 1987

Big Game	\$33 62
Non Game	\$28.01
Other Game	\$21.29
Wildlife and Fish Rec Use	\$23 53
Furbearer (\$/M Pelts)	\$30,304.00

**FIGURE III-7
TRENDS OF WILDLIFE WFUDs**

When Tables III-15 and III-16 are put together, they show the wildlife value on the Forest to be about \$40,000,000 and rising.

8. FISHERIES

a. Overview

Fish and the aquatic resources on the Wenatchee National Forest provide major recreational and aesthetic assets. Commercial and sport fisheries depend upon the Forest ecosystem to provide spawning and rearing habitat, as well as a quality source of fresh water for downstream fisheries. Maintenance and improvement of current habitat, along with protection of long-term fish habitat and water quality, is a strong concern of the public, State and Federal natural resource agencies, and representatives of the Colville and Yakima Indian Nations.

The Forest has about 241 lakes and reservoirs and 1,769 miles of streams and rivers that support fish. Approximately 806 miles of streams and one large lake are available to anadromous fish.

The feasibility of reintroducing sockeye salmon into the Yakima system is currently being investigated. It is estimated that an additional 260 miles of streams also provide fish habitat.

The Forest has very few detailed stream or lake surveys to evaluate fisheries production, habitat potential, or susceptibility to environmental impacts. Therefore, numbers or pounds of fish and habitat capability estimates shown in this document are only a best approximation based on existing knowledge. Recent work, funded by the Forest, Indian Tribes, Chelan County PUD, state and federal fish management agencies, is beginning to fill some of the gaps.

Nationally (in 1977) the Forest ranked sixth, among the 154 National Forests and 19 National Grasslands, and first, in the Forest Service Pacific Northwest Region, for recreation visitor days spent in cold water fishing (USDA Forest Service, 1982). Calculation of recreation visitor days in 1984 showed that there were 192,800 days spent fishing or about 580,000 actual fishing trips. Of these, 65 percent or approximately 125,000 days were in roaded areas and 67,000 in roadless areas.

The aquatic habitats support 15 species of coldwater game fish and 3 species of warmwater game fish (Table III -17). Five species of coldwater anadromous and resident salmonoid species

account for 95 percent of the angling. Four percent of fishing is distributed among the other cold water species, while less than one percent is spent in warm water fishing.

TABLE III-17
SPECIES OF GAME FISH ON THE
WENATCHEE NATIONAL FOREST

COLD WATER ANADROMOUS	COLD WATER RESIDENT	WARM WATER RESIDENT
Chinook salmon	Kokanee salmon	Smallmouth bass
Sockeye salmon	Mountain whitefish	Largemouth bass
Coho salmon	Pygmy whitefish	Yellow perch
Steelhead trout	Golden trout	
	Cutthroat trout	
	Rainbow trout	
	Lake trout (Mackinaw)	
	Brown trout	
	Brook trout	
	Bull trout (Dolly Varden)	
	Burbot (ling cod)	

A primary management consideration, on the Wenatchee National Forest, are the fisheries rights reserved to the Indians by the Yakima Treaty of 1855. The Yakima Indian Nation is concerned for the development of environmental standards which ensure the protection and/or enhancement of the fisheries resource (Jim, 1981). Litigation concerning the protection of water quality and fish spawning habitat has emphasized the responsibility of the Forest Service for those treaty resources reserved to the Indian tribes of the Pacific Northwest (Northwest Indian Cemetery Protective Association, et al., V. R. Max Peterson, et al. 1983). This responsibility includes protection and enhancement of the fishery given the resources and abilities available (U.S. et al. v. State of Washington, et al., No. 81-3111 9th Cir. 1982).

Resident Fish

Resident trout fishing makes up the majority (95 percent) of the recreational fishing on the Forest and, therefore, its continuance is of major concern. Although most Forest streams have very low productivity due to low nutrients and cold water, recent measurements of rainbow trout in the Yakima River system indicate one of the best growth rates documented in North America

FISHERIES

(Washington State Department of Wildlife, 1984). This may be partially due to the long-term reduction in competition with anadromous fish and the high nutrient content due to cropland runoff.

Self-sustaining wild populations of resident trout inhabit most of the Forest's streams. Because of heavy fishing pressure on the roaded portions of the Forest, wild resident trout populations are often supplemented with periodic stocking by the Washington Department of Wildlife (WDW). Some popular rivers stocked with catchable adult fish are the Tieton, Wenatchee, Little Naches, Naches, Chiwawa, and Entiat Rivers, and Icicle and Peshastin Creeks. WDW also stocks many suitable high altitude and/or previously barren lakes.

Of special importance for the resident fishery is the WDW's egg-taking facility for cutthroat trout at Twin Lakes near Lake Wenatchee. These eggs provide fish for many high lakes around the State. A kokanee egg source is available on the North Fork of the Tieton River below Clear Lake. This egg source could be utilized to raise fingerlings for stocking around the State.

Only one lake on the Forest, Fish Lake near Lake Wenatchee, provides a significant warmwater fishery. Yellow perch and smallmouth and largemouth bass inhabit this lake. One resident trout variety, the bull trout, is listed as a Category 2 species by the USDI Fish and Wildlife Service.

Anadromous Fish

Four species of anadromous fish, including steelhead trout and chinook, sockeye, and coho salmon, utilize the Forest for spawning and rearing. Numbers of all species, except sockeye,

are less than the historical run levels which occurred prior to the construction of irrigation diversions and the mainstem Columbia River dams, and prior to the onset of large commercial fisheries. Part of the decline could also be attributed to effects of land use activities such as mining, logging, and grazing.

The Northwest Power Planning Council has established a goal of doubling the anadromous fish runs into the Columbia River System. Attainment of this goal will require cooperation and coordination between Treaty Indian Tribes, State and Federal fish management agencies, power companies and land management agencies, such as the Forest Service. The Forest, as the managing entity for approximately 77 percent of the Wenatchee River watershed, 84 percent of the Entiat and 23 percent of the Yakima River watersheds, will play a major role in reaching fish production goals for those drainages. The Forest is currently investing appropriated money in the Subbasin Planning Process and, will develop an aggressive fish habitat management program through implementation of "Rise To The Future" (the National Forest System Fisheries Initiative) and the Forest Plan.

Maintenance of current anadromous fish habitat quantity and quality, protecting long-term habitat capability, and improvement of habitat degraded by past activities, is an important component of efforts to achieve fish production goals. Habitat on the Forest is vital to the production of wild and naturally reproduced populations. These wild populations often form the nucleus for further production increases and provide a vital genetic resource for long-term population viability.

^{1/} Assumes passage provided into Cle Elum system.

Fisheries are also regulated based on the health of the wild populations. Table III-18 displays the current estimated average anadromous run sizes attributable to the Forest, including production from private lands intermingled within the Forest boundary.

The habitat is believed to be capable of producing much larger numbers of anadromous fish. Because numbers of returning adults are not necessarily a measure of the ability of the habitat to produce fish, smolt habitat capability (SHC) is used to measure habitat potential. These numbers are also being developed by the agencies, and the chart above represents only a best approximation.

Estimated smolt losses on the downstream migration are approximately 15 percent per dam and adult losses on the upstream migration are approximately 5 percent per dam (Table III-20). It is generally agreed that full production in the Yakima, Wenatchee, and Entiat Rivers cannot be achieved, due to the passage problems, without supplementing natural production. Management of the Forest habitat is vital to providing habitat for the natural component.

The Northwest Power Planning Council's Fish and Wildlife Program (amended 1984) has identified downstream and upstream migratory problems of the mainstem Columbia River hydroelectric dams as a major factor limiting anadromous fish production. The program includes numerous measures to attempt to reduce the losses.

Following is a brief discussion of each species of anadromous fish as it applies to the Wenatchee National Forest.

TABLE III-20

EFFECTS OF DAMS ON THE FOREST'S ANADROMOUS FISH

	Percentage of Smolts Lost	Percentage of Adults Lost	No. of Dams
Yakima River	48	19	4
Wenatchee River	68	30	7
Entiat River	73	34	8

Sockeye

The Wenatchee River system supports the only remaining run of spawning sockeye salmon on the Forest. The size of the run varies considerably from year to year with an average run of approximately 31,000 fish which may be close to the historical run size. Historically, the Yakima River system also produced a large sockeye run. However, barriers, including Cle Elum, Kachess, Keechelus, and Bumping Lake Dams, have blocked all access to the lake habitat. The result has been complete elimination of sockeye in the Yakima system. The National Marine Fisheries Service is currently doing a feasibility study of reintroducing sockeye salmon to the Yakima system. There are also plans to supplement sockeye production in Lake Wenatchee by net rearing pens. Historically, there has been a fluvial (river) sockeye population in the Entiat River, too.

A recent publication, Determinants of Sockeye Salmon Abundance in the Columbia River by James W. Mullan (Fisheries Assistance Office, U.S. Fish and Wildlife Service, Leavenworth, WA., Draft Report FRI/FAO-84-3, June 1984), reviews most of the sockeye information available for the Columbia Basin including all the Wenatchee National Forest's rivers.

Coho

The Yakima River system supports a very small run of coho salmon of which all are probably of hatchery origin. At least 237 miles of anadromous fish habitat have been lost in the system due to the cumulative effects of diversions, dams, and insufficient low flows. Based on historical run size and geographic distribution of known habitat (stream miles), 42 percent or 50,000 to 70,000, of the coho salmon from the upper Columbia River would have originated in the Yakima River drainage. Similar values for other Forest upstream tributaries would have been: 5 percent in the Wenatchee, or 6,000 to 7,500 coho, 8 percent in the Entiat, or 9,000 to 13,000 coho (Mullan, 1983).

The report, Overview of Artificial and Natural Propagation of Coho Salmon (*Oncorhynchus kisutch*) on the Mid-Columbia River by James W. Mullan (Fisheries Assistance Office, U.S. Fish and Wildlife Service, Leavenworth, WA., Report No. FRI/FAO-84-4, December, 1983), reviews the recent history of the coho salmon in the Wenatchee and Entiat Rivers and indicates that natural and artificial (hatchery) runs are now practically nonexistent. The report concludes that reestablishment of runs have failed primarily due to necessary reliance on lower river fish stock which lack genetic suitability.

Chinook

Chinook salmon are found in all the major river systems of the Forest: the Yakima, Wenatchee, and Entiat Rivers. Three runs are commonly delineated in the Columbia system. The spring chinook, entering the Columbia River mouth in the spring and spawning in the late summer, are most dependent on Forest habitats since they use the upper river reaches. Summer chinook enter the Columbia River mouth in the summer and spawn later than the spring chinooks, using mid-river reaches. Summer chinook utilize habitats on the Forest only on portions of the Wenatchee River between the mouth of Tumwater Canyon and Lake Wenatchee. Fall chinook, to a large extent, use the mainstem Columbia River and lower Yakima River and therefore are not directly dependent on Forest habitats.

While chinook runs in the Wenatchee, Entiat, and Yakima river systems are supplemented with hatchery fish, a significant portion of the returning spring chinook to the Wenatchee and Entiat rivers and summer chinook returning to the Wenatchee River are wild fish produced within the National Forest boundary.

In the Yakima system, a major research project on spring chinook enhancement is being funded by the Bonneville Power Administration and conducted by the Yakima Indian Nation with scheduled completion in 1990. The Yakima system is being used as the "showcase" by the Northwest Power Planning Council in its Fish and Wildlife Program to show the benefits of offsite enhancement and mitigation of hydroelectric

projects (Northwest Power Planning Council, 1984) Chinook salmon are the primary enhancement species. Efforts to use the Yakima Basin for offsite enhancement could be complimented by the Yakima River Basin Water Enhancement Project. That study may lead to improved in-stream fish flows throughout the Basin.

Spring chinook production within the Wenatchee drainage will soon be supplemented under terms of the Rock Island Settlement Agreement. The project will include trapping wild spring chinook adults from the Chiwawa River, a Wenatchee River tributary, then spawning the adults and initially rearing the progeny at the Chelan County PUD facility at Eastbank. The fry will then be transferred to a satellite rearing facility located on the Chiwawa River on National Forest land, and eventually released directly into the Chiwawa

Steelhead Trout

Steelhead trout, the sea-running relative of the resident rainbow trout, are found in the three major Forest river systems. Like other species of anadromous fish, their habitat and run sizes have been greatly reduced by barriers and habitat alteration. Current runs are composed of a mixture of natural and hatchery produced fish

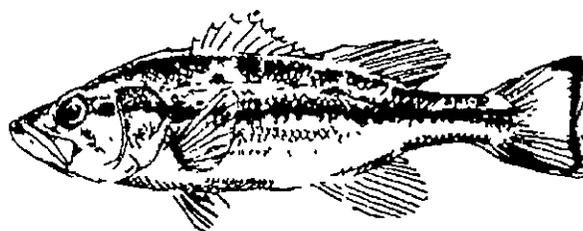

If location, methods, and season for fishing are not adequately controlled, young steelhead can inadvertently provide a major "resident trout" fishery. The Washington Department of Wildlife, in their fishing regulations, is actively attempting to reduce these incidental catches. In addition, attempts are being made to limit sports harvest to hatchery reared adult fish, allowing returning wild adult fish to escape to the spawning areas

b. Demand for Fish

The demand for fish, and therefore high quality fisheries habitat, is not readily measurable. For anadromous fish, which are commercially harvestable, there appears to be practically an inexhaustible demand. At one time, commercial landings of Columbia River fish were over five times their present level, indicating that demand is very high. Treaty rights reserved in the Yakima Treaty of 1855 include considerable demand for increased fish production over the present

Resident fish demand is also unquantifiable, but very high. To meet a portion of the demand, the Washington State Department of Wildlife has fish planting programs in streams and lakes. There is no indication that there is a limit to the numbers of fish, of appropriate species and size, that could be harvested (Washington Department of Wildlife, James Cummins, personal communication, March 1985)

Due to the high demand for fish, the maintenance, rehabilitation, and enhancement of fisheries habitat is of primary concern to the public, tribes, and Federal, state, and local governmental agencies.

c. Management Indicator Species

To measure the effects of land and resource management practices on the many fish species and on the integrity of the aquatic habitat, management indicator species are used as a tool. These species are chosen to represent all other species. In other words, it is assumed that if the needs of the management indicator species are met, then the needs of all other species living in similar habitat are also met.

For fish, anadromous salmonids, bull trout, and cutthroat trout (resident) have been chosen as the management indicator species. These species, along with the beaver (discussed in the wildlife section of this chapter), represent all species dependent on high quality habitat in the riparian-aquatic zone. Anadromous fish, including spring and summer chinook salmon, sockeye salmon and steelhead trout, are chosen because of their commercial, recreational and cultural values. These fish are also dependent upon complex aquatic habitat, which differ by species and life cycle stage. Anadromous fish population sizes may be below full habitat production potential and may not fully represent the effects of land management. However, quantifying habitat production potential, and preserving that potential, is important to fish production goals.

Resident cutthroat trout are also an indicator of aquatic habitat especially in streams which do not support anadromous fish. Bull trout are chosen because they are a Regional Forester's Sensitive Species.

d. Threatened, Endangered, and Sensitive Species

There are no species of Federally designated threatened or endangered fish known to inhabit the Forest. One fish species, the bull trout, is listed as a Category 2 Species by the USDI Fish and Wildlife Service. Little is currently known about bull trout habitat requirements or distribution.

e. Fisheries Habitat

At first glance, fish habitat on the Forest appears to be in fairly good condition overall. However, the lack of recent inventory information needed to quantify current habitat, changes from the historic condition, and potential for improvement, makes it difficult to assess habitat condition. In some locations, habitat impacts, such as the effects of mining, road location, firewood cutting and timber harvest, are easily observed. Visual evidence of adverse habitat impacts is not so easily discernable in other areas. For example, historic logging in the riparian zone accompanied by stream cleanout and log drives may have often reduced habitat complexity. Man-caused fish passage barriers may also limit the amount of habitat available for fish production. Some barriers, such as culverts, may be on the Forest.

For resident trout, it is not known whether there is a net significant loss in habitat quantity and quality from the historic levels. In fact, for resident fish, there is now a significantly greater area of habitat available, without anadromous competition, than there was fifty years ago.

9. VEGETATION

Vegetation on the Wenatchee National Forest is a complex mosaic of plant communities. These plant communities reflect variations in landform, elevation, aspect, moisture, and soils. They have also been modified by the influence of fire, insects, disease, grazing, logging, and the introduction of non-native plants. Identifiable associations of vegetation occur as repeating patterns within this mosaic.

The area that the Wenatchee National Forest encompasses is extremely diverse. The plants and animals, and the ecosystems of which they are a part, are many and varied. Biological diversity is undoubtedly different now than it was in the past or will be in the future. Change in diversity is ongoing and natural but is also affected by management activities. Consequently, diversity changes are a critical consideration in all that we do.

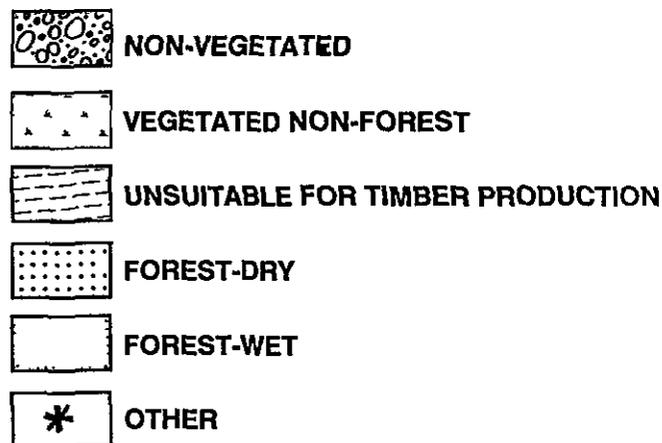

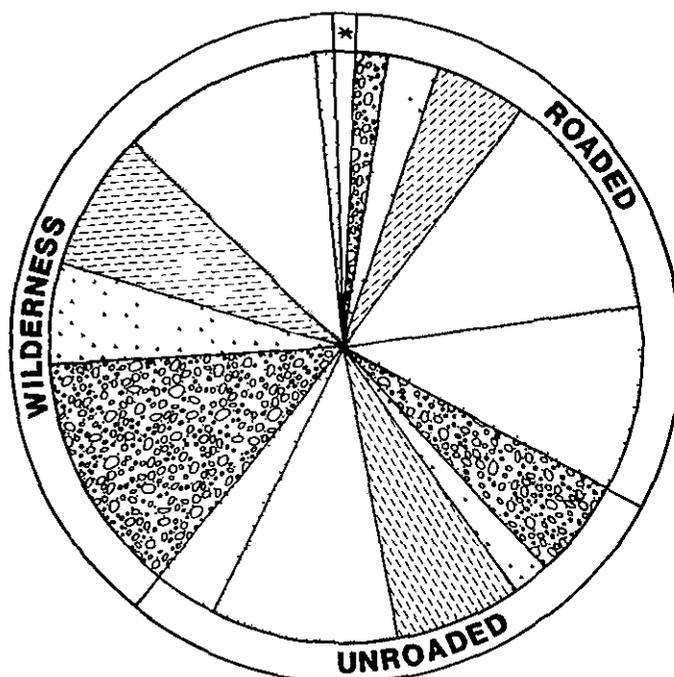

Biological Diversity

A number of definitions exist for biological diversity, both legal and operational. In simple terms however, biological diversity is the distribution and abundance of different plant and animal communities and species. Diversity is characterized by a number of attributes, the complexity of which makes the understanding of this important issue difficult. Measures of diversity must include attributes that involve time, space, and organisms because diversity change relates to all these things. Biological diversity has not been characterized in any objective way on the Wenatchee National Forest at this time.

Biological diversity touches many planning issues. Issues related to forest structure distribution over time potentially affect diversity. These issues include the amount and distribution of old-growth forest; the conversion of hardwood-dominated stands to conifer-dominated stands; the amount and rate of timber harvested; the amount, quality, and distribution of animal habitat; and the structure of our streams. Other issues are commonly related to species composition concerns - such as sensitive plants and animals, management indicator species, and species diversity.

The tremendous diversity of cutting intensity, fires, insects, and diseases will continue the diversity of vegetation on the Forest. The graphics below show the acres and percentages of the current vegetative conditions on the Wenatchee National Forest.

* Includes acres of water, RNA's, botanical areas, developed recreation, roads, special uses, administrative sites and utility corridors

Because of the complexity inherent in the environmental component of vegetation, it has been divided into subcomponents: trees; old growth; forage; unique ecosystems; sensitive plants, Research Natural Areas; and Entiat Experimental Forest.

9a. VEGETATION: TREES

a. Overview

Conifer forest ecotypes occupy approximately 69 percent of the Forest. Elevation, soil types, precipitation, and aspect combine to create a wide variety of ecological vegetative types. For simplicity, these can be combined into the following three forest ecotypes which occur on both suitable and unsuitable land:

Dry Forest (Ponderosa Pine/Douglas-Fir)

The low elevation, dry sage brush, bitterbrush, grass type along the east edge of the Forest changes to the ponderosa pine/Douglas-fir zone with increasing elevation and moisture. Pine-grass, elk sedge, kinnikinnick, serviceberry, and ocean spray are some of the common understory plants.

Past logging, fires, disease, and insects have created a predominately two-storied stand condition in this type. The stand class distribution is shown in Table III-22.

TABLE III-22
DRY FOREST ECOTYPE
STAND CLASS DISTRIBUTION

Stand Size Class	Acres	% of Tentatively Suitable Acres ^{1/}
Mature Stands	48,399	6.1
Immature Two-Storeyed Stands	106,828	13.5
Pole Stands	91,013	11.5
Seed and Saplings	47,488	6.0
Bare Ground	1,123	.1
Subtotal	294,851	37.2

^{1/} See Table III-25

Timber harvesting is common in this zone with the earliest commercial timber sales dating back to 1910. Early sales concentrated on the harvest of ponderosa pine which was used to make apple boxes. Timber production potential is approximately 52.3 cubic feet (280 board feet) of tree growth per acre per year, although this is quite variable depending on local site conditions and intensity of management. This production estimate is based on performing three thinnings (1 precommercial and 2 commercial) and a clearcut harvest at about age 120. On some of the dry site areas, either shelterwood or uneven-aged management may be needed to assure regeneration. This determination is made on a site specific basis by certified silviculturists.

Wet Forest (Mixed Conifers)

The wet forest zone is characterized by a wide variety of plant species. Ponderosa pine may be present, but without disturbance it will gradually be replaced by shade tolerant grand fir, silver fir, western hemlock, or western red cedar. Less abundant, but highly valued trees because of their wood and aesthetic qualities, are western larch, noble fir, and western white pine. At the upper elevations in this zone, lodgepole pine, mountain hemlock, subalpine fir, and Englemann spruce become more prevalent.

The most common mixed conifer wet forest type is Society of American Foresters (SAF) type 213 grand fir (Eyre 1980). The next most common type is SAF 206 Alpine fir-Englemann spruce. However, on the Wenatchee, much of the area in this type has a large component of pacific silver fir.

Douglas-fir and ponderosa pine are common tree species in the drier portions of the moist forest. However, in the absence of fire or other major disturbances, both these species will be replaced by the more tolerant grand fir, silver fir, sub-alpine firs, hemlock, or cedar.

Lodgepole pine (218) and western larch types (212) are even more dependent on fire for maintenance. Most sites occupied by these species are the result of hot fires that killed the more shade tolerant species.

High elevation types include mountain hemlock (205), and white bark pine (208). These are combined with areas of alpine larch to form a type classified by Hall (1978) as CA Alpine open park type. This open park condition is an important dispersed recreation and big game summer forage area. The intermingled grass forb communities in the high mountain meadows contain highly palatable protein rich forage. Fire in these areas can shift the vegetative cover from conifers to shrubs including huckleberries, mountain ash, and mountain maples. These can persist for many years before being replaced again by conifers.

Hardwoods that are common along drainageways at both low and moderate elevations are black cottonwood, white alder, river birch, and aspen. They usually occupy sites with high water tables. Only black cottonwood is presently used for commercial wood products in significant volumes and is occasionally planted in wet areas for commercial use.

The most common mid-elevation shrubs are vine maple, salal, salmonberry, devil's club, Oregon grape, sticky currant, and elderberry. Elk sedge and pinegrass are also very common.

TABLE III-23

**WET FOREST ECOTYPE
STAND CLASS DISTRIBUTION**

Stand Size Class	Acres	% of Tentatively Suitable Acres 1/
Mature Stands	191,904	24.2
Immature Two-Storeyed Stands	127,201	16.0
Pole Stands	134,323	16.9
Seed and Saplings	37,269	4.7
Bare Ground	8,162	1.0
Subtotal	498,859	62.8

1/ See Table III-25

The wet zone has considerably more mature forest and bare ground than in the dry forest zone. Most of the bare ground acres are from recent clearcuts and fire. The increase in even-aged mature stands reflects less frequent fire occurrence.

Timber production is estimated at 60.3 cubic feet (323 board feet) per acre per year when a three thinning (one precommercial and two commercial) regeneration harvest system is used with final harvest at about age 110. Timber, recreation, wildlife, and water are the resources that are emphasized in this zone.

Sub-Alpine Parkland and Mountain Meadows

This zone is best known for its wide variety of flowering herbs and forbs. Parklike stands of whitebark pine, Engelmann spruce, subalpine fir, and alpine larch adjoin the barren or treeless upper mountain slopes. Much of this zone is in wilderness and unroaded recreation areas.

Dispersed recreation is the primary management emphasis in this zone. Some portions of this zone are grazed by domestic sheep. The heavy precipitation and snowpacks in this zone contribute greatly to the Forest's annual stream runoff.

b. Timber Management

In both the dry and wet zones, the most common conifer species is Douglas-fir. However, old-growth ponderosa pine receives the most interest from local sawmills. Douglas-fir and ponderosa pine make up 50 percent of the existing volume of timber on the Wenatchee. The 16 species of conifers in order of standing volume from the 1977 Forest inventory are shown in Table III-24.

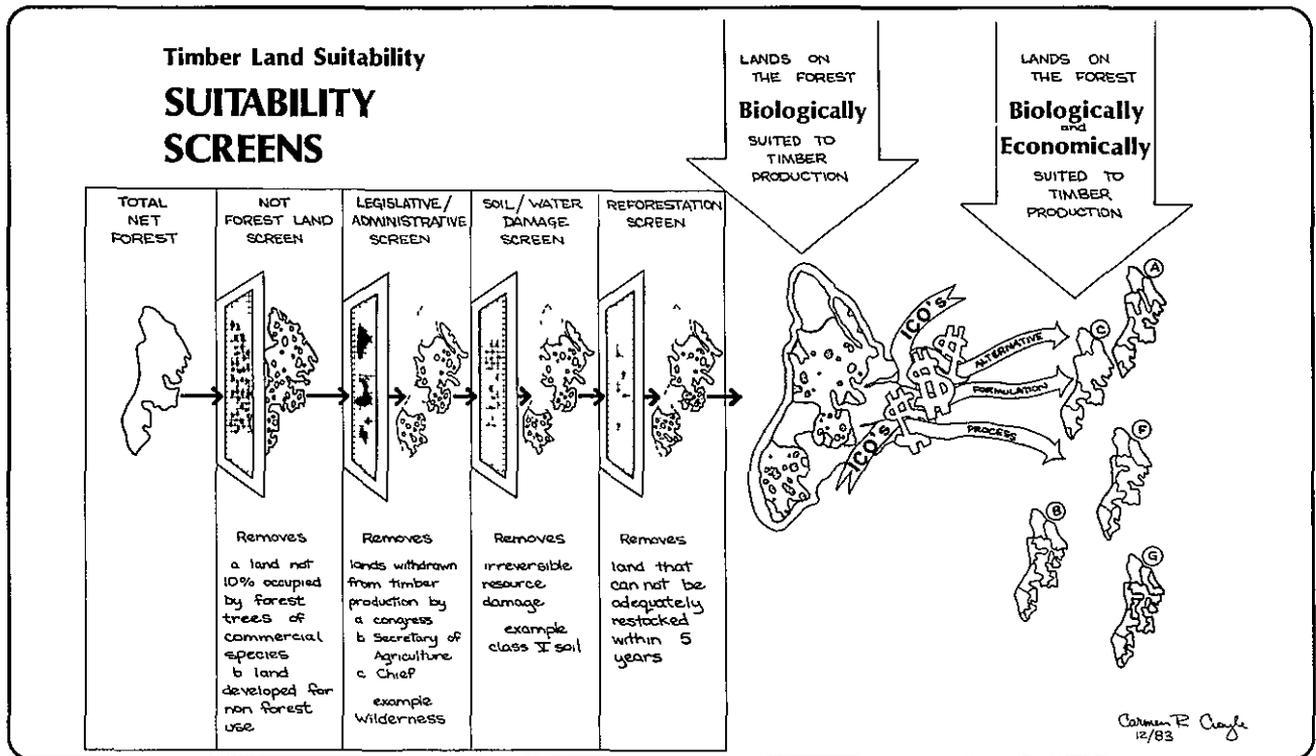

TABLE III-24

**STANDING VOLUME OF WENATCHEE
NATIONAL FOREST CONIFER SPECIES**

Species	% Standing Volume
Douglas-fir	37%
Ponderosa pine	13%
Pacific silver fir	11%
Grand fir	7%
Lodgepole pine	6%
Western hemlock	5%
Subalpine fir	5%
Western larch	5%
Mountain hemlock	4%
Englemann spruce	3%
Western white pine	2%
Western red cedar	1%
Alaska yellow cedar	1%
Noble fir	
Whitebark pine	
Subalpine larch	

The process for the determination of which lands are suitable for timber production is indicated by Figure III-9. The details for this process are included in the planning records located in the Forest Supervisor's Office.

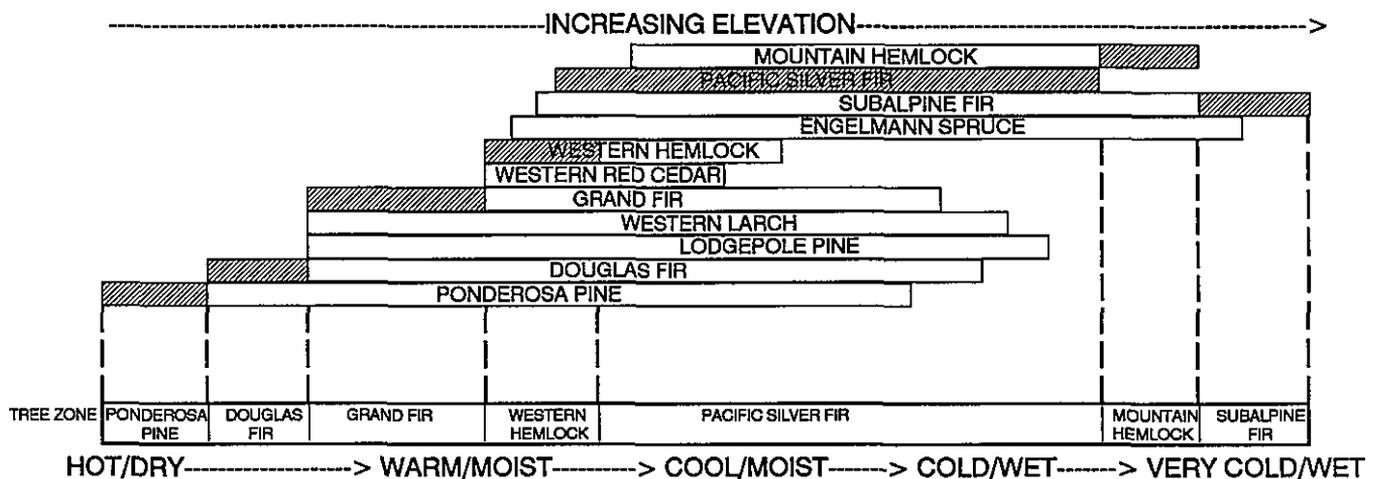

**FIGURE III-9
TIMBER SUITABILITY SCREEN**

Of the 2,164,180 acres of Wenatchee National Forest, 791,899 acres, or 37 percent, are tentatively suitable for timber production. These lands are capable of growing industrial wood and are available and suitable for timber management activities.

Table III-25, following, summarizes Forest land suitability for timber production. (For details of the suitability process see Field Review Timber Land Suitability, Wenatchee National Forest, 1984.)

**FIGURE III-10
DISTRIBUTION OF MAJOR TREE SPECIES WENATCHEE NATIONAL FOREST**

Schematic distribution of major tree species usually encountered with increasing elevation in mature upland forest stands on the Wenatchee National Forest. That portion of the tree species range where it is considered climax is shaded. Zone refers to that area where a particular tree is climax dominant.

TABLE III-25

2. Research Natural Areas	1,038	
3. Other such as:		
Turnwater Botanical Area	784	
Entiat Experimental Forest	4,219	
Subtotal	436,829	
B. Lands growing less than 20 cu. ft./ac /yr.		
1. Lands classified as unsuitable	137,717 ^{2/}	
2. Lands classified as suitable		(6,148) ^{3/}
3. Lands classified as separate suitability component	0	
C. Irreversible resource damage (219.14(a)(2))	18,720	
D. Regeneration Difficulty (Reforestation cannot be guaranteed) (219 14(a)(3))	65,933	
E. Regeneration difficulty-lands classified as a separate suitability component	0	
IV. Tentatively suitable Forest Land		791,899
V. Total of Nonsuitable Land	1,372,281	
VI. Land status under current Timber Management Plan Revised/Approved 10/19/84	Standard Special Subtotal Marginal TOTAL	682,251 105,500 787,751 102,000 889,951

^{1/} Includes Alpine Lakes Management Area Non-harvest land allocations

^{2/} Due to reforestation difficulty.

^{3/} Currently producing less than 20 cubic ft /ac /yr but can be reforested

This tentatively suitable forest land (791,899 acres) is slightly higher than the current timber management plan standard and special acres of 787,751. Most of the marginal acres have been reclassified as unsuitable.

The current timber harvest level as revised after the Washington State Wilderness Act of 1984 is:

	Million Board Feet	Million Cu. Ft.
Annual sale quantity	170.9	31.4
Unregulated volume	5.9	1.0
	176.8	32.4

Predicted future harvest levels depend upon the amount of investment in prompt reforestation, thinning and weeding, fertilization, and tree improvement. Tree improvement involves selection of the best parent trees for seed and seedlings for reforestation through the use of seed orchards and genetic tests.

c. Reforestation

Prompt planting immediately after fire or logging is the general rule on the Forest. Historically, 90 percent of the clearcut acres are planted. Only those acres where natural regeneration of the desired species is assured within five years are left for natural regeneration. Approximately 50 percent of the shelterwood acres are planted.

Aerial seeding is used for wildfire areas when not enough seedlings are available or the area is too rocky for successful planting. Wildfire areas which have been successfully seeded include portions of the 1970 fires on Chelan and Entiat Districts, and the Hornet Creek burn. Few, if any, seedlings were found after seeding with tree seed mixed with grass seed on the Mineral Springs fire or the Eight-mile fire. However, this method was used for the steep rocky portions of the Five-mile fire in September 1985 and portions of the Dinkleman Fire in 1988.

Planting acres during the 1970's, following the Entiat-Chelan burns, rose to over 5,000 per year. All suitable 1970 fire acres have been planted, except some that have poor access. Reduced timber harvest and completion of the backlog led

to a low of 1,852 acres planted in 1983. Expected future planting is shown on Table II-3a by alternative. Current planting of seedlings originating from tree improvement seed has increased to 70 percent. These seedlings are from specially selected trees chosen for good growth, form, and disease resistance.

The best of these seedlings will be allowed to crossbreed in specially designed seed orchards to increase future yields. The oldest seed orchard trees were planted in 1980 on the Naches and Cle Elum Ranger Districts. Of the 16 species present on the Forest, only six are considered important enough commercially to warrant investment in tree improvement activities. The six tree improvement species are Douglas-fir, ponderosa pine, western white pine, noble fir, pacific silver fir, and western larch. Seed orchards have been established for all six except western larch. Seed for other species will come from felling or climbing wild trees that appear to have desirable characteristics.

d. Timber Stand Improvement (TSI)

An estimated 15,474 acres are in need of precommercial thinning (Wenatchee Reforestation TSI Needs Report). Many of these stands originated after the 1970 fires on the Chelan and Entiat Districts. In order to precommercially thin these stands at approximately the optimum age, the Forest proposes thinning a minimum of 2,000 acres each year for 10 years. Precommercial thinning was accomplished on 2,880 acres in 1984, 3,062 acres for 1985, and 3,435 acres in 1986.

The Timber Stand Improvement Needs Report shows release of conifer trees from other vegetative competition is needed on 5,091 acres. Potential treatment methods include herbicides, grazing, mechanical methods, and hand cutting or pulling. In 1983, conifers were released from competition on 753 acres. However, the work accomplished in 1984 was drastically reduced due to a Federal court order banning herbicide use in Washington and Oregon pending a "worst case analysis" of potential impacts on human health.

Researchers have concluded that brush will have an adverse effect on growth and yield of conifer plantations (McDonald and Oliver, Forestry Research West, 1985). They also state that aerial applications of herbicides are the most effective and economical brush control technique. At the same time, there has been considerable public concern about potential health and environmental impacts of herbicide spraying in some areas of Oregon and Washington. Past public opposition to herbicide use on the Wenatchee Forest has been less intense than on other forests, perhaps due to intensive agricultural use of such chemicals on private lands in eastern Washington.

The primary herbicides the Forest uses for vegetation control are Velpar (hexazinone) and Roundup (glyphosate). As relatively few acres are treated, no reduced annual allowable harvest has been calculated if herbicides can not be used in the future. However, some treatments such as hand cutting vine maple or large hand-scalping in pinegrass will be more expensive than chemical treatments. Some hand methods, such as pulling out ceanothus, may actually be cheaper and more species specific than herbicides.

Some acres on the Wenatchee lend themselves to vegetation control through sheep or cattle grazing. Areas of tall brush or steep, erosive sites do not lend themselves to brush control by livestock, and there is potential for damage to young tree seedlings. For example, a trial utilizing sheep to graze domestic grass created a need to replant several acres of planted pines in the Mineral Springs fire area south of Swauk Pass. The sheep also caused soil displacement in this generally very steep area. Successful release of young seedlings have been experienced by using sheep where succulent forbs are available for grazing and where sheep are moved before they begin to eat the trees. An environmental analysis is planned in 1990 to deal with the existing areas where trees are in danger of being out competed by brush or other vegetation.

e. Forest Insects and Diseases

Insects and disease cause an estimated 11.4 million cubic feet (62 MM Board feet) of timber loss per year. The loss to disease alone is estimated to be 30 percent of the Forest's potential tree growth (Hadfield, 1982).

Selective logging and uneven-aged management increase disease and insect losses in many sites. Root rot, especially Phellinus weirri, was found to infect about one-third of the trees left in a partial cut stand at Naches (Filip 1979). Dwarf mistletoe is also a common problem in partial cut stands on the forest.

The shift in inventory volume from pines to firs through partial cutting increases the probability of western spruce budworm, and Tussock moth outbreaks. The budworm was aerial sprayed using the chemical BT on approximately 43,000 acres of grand fir and Douglas-fir trees on the Naches Ranger District in 1986. During an eight year period, 1971 through 1978, the budworm defoliated 793,000 acres from Ellensburg north to Chelan. Aerial spray treatments in 1976 and 1977 appeared to reduce damage and population levels to endemic levels by 1979.

Although the budworm affects large acreages, bark beetles actually kill more timber. The most important bark beetle on the Forest is the mountain pine beetle. Average loss is 5 million board feet per year. In the past, this was primarily in western white pine. However, pole-sized stands of ponderosa pine and lodgepole pine are susceptible if density is not controlled by thinning.

Thinning to promote healthier and more rapid growing trees is the best approach to prevent outbreaks of mountain pine beetle in ponderosa pine (Sortwell 1975). For mature lodgepole pine stands, cutting a series of small blocks so a mosaic of age classes result is recommended to reduce future losses (Safranyik 1974.) This is the current strategy being used on the upper elevations of the Entiat District. Logs are being utilized by the Big Toy Mill for construction of playground equipment.

Of special concern for the future is the potential for a beetle infestation in thousands of acres of even-aged stands of lodgepole pine that originated after the Entiat-Chelan fires of 1970. Without early precommercial thinning, these stands will become susceptible to beetles by the year 2020.

f. Timber Harvest

From 1910 until about 1955 selective removal of the largest, most valuable trees was the predominant harvest method on the Wenatchee. On acres where disease-free small trees of desirable species were present, this was a cost efficient and silviculturally acceptable method. This is still true today.

Since about 1955, increased use of shelterwood and clearcutting methods to reduce mistletoe, root rots, and undesirable species has increased. Currently overwood removal from shelterwoods and natural two-storied stands accounts for about 50 percent of the Forest harvest. Clearcutting has increased to approximately 3,000 acres per year or about 30 percent of the Forest harvest volume. The remaining volume is from salvage and commercial thinning areas.

Tree removal methods to implement the above silvicultural treatments include all methods from horses to helicopter. Historically, horses and then tractors, were the primary methods of log skidding. Ground skidding machines, including tractors and rubber-tired vehicles, are still the most common logging method used today.

The proposed five year timber sale schedule has the following amounts of each logging method:

LOGGING SYSTEM METHODS				
Tractor	High Lead	Skyline	Longspan Skyline	Helicopter
41%	15%	31%	10%	3% 1/

1/ Additional helicopter volume will occur due to the Dinkleman Fire that was not planned when the timber sale schedule was prepared.

Explanation of these methods and typical use is shown below:

Logging Systems:

Tractor - Use of tracked or rubber-tired vehicle to skid logs to a central loading point. This method is typically used on dry, gently sloping ground.

Highlead - A cable system operated from a tower, which drags logs to a central loading site. One end of a log may be lifted off the ground for short distances. Used most often in moderately steep terrain over relatively short distances.

Skyline - The log yarding cable is attached between a tower and an elevated point in the distance. Logs are transported partially or completely suspended above the ground with a movable carriage on the cable. Used in steep or unstable terrain with minimal impacts on the land, this method can reach for long distances.

Helicopter - Use of helicopter to lift logs from a logging site to a nearby central loading point. Most economical on relatively remote and difficult to reach sites. Avoids road building where roading is inappropriate because of steep terrain, unstable soils, visual considerations, etc. Also very applicable to rapid removal of fire-killed timber over large areas such as the Dinkleman fire.

g. Costs and Returns

Recent concerns about deficit (below cost) timber sales have focused attention on the costs incurred in preparing and administering a timber sale project compared to the cash returns and values generated from the timber harvested. The occurrence of a "below cost" program is dependent on the analysis approach used. For example, Tables III-26 and 27 are a comparison of returns and values generated from harvest activities yearly from 1980 through 1984 with the expenditures for preparing the timber sale programs for 1980-1987. It is important to understand that the costs displayed are for preparing sales to be sold that year and for the next 2 to 4 years. These costs also continue after the sale is sold in the form of contract administration costs and monitoring costs. Costs incurred or generated by a specific timber sale often span a period of 10 years, commencing with the start of sale planning and ending with the completion of post sale activities such as reforestation and certification that the harvested area is satisfactorily reforested. The cash returns and values are generated by actual log removal from sales that were sold prior to the year of the returns. The returns and values from a specific timber sale frequently occur over a period of 1 to 5 years after a sale is sold. Very few timber sales are completely harvested in 1 year or during the same year it was sold.

Two different cost bases are displayed. The first cost (Resource Support) is a budget cost that represents all timber sale support costs in the budget appropriation. These costs include budget items for slash disposal (site preparation) and cooperative work as well as resource specialist support. Resource specialist support are costs incurred by specialists in differing resource areas assisting in preparing environmentally sound timber sale proposals. These resource areas include: fire management, range, minerals, geology, recreation, cultural resources, wildlife, soil and water, lands, and engineering. The second cost (Timber Costs) reflects those costs incurred in sale preparation, sale administration, sale planning and inventory, sale stand exams, and reforestation and timber stand improvement. The total of the two costs reflect as nearly as possible the amount of money Congress appropriates to finance the timber sale program on the Wenatchee National Forest for a given year.

The returns and values reflect the total monies and values received by the Forest Service for timber removed from the Wenatchee National Forest. The returns and values include deposits made to the National Forest Fund (NFF), Knutson-Vandenberg collections (K-V), Road Value (Purchaser Credit), Slash Disposal (BD) collection, Salvage Sale Fund (SSF), and Cooperative Deposits for Erosion Control, Scaling, Road Maintenance, etc. (CWFS). These are all returns or values that serve to offset costs or pay for work done by the Forest Service made necessary by the timber sale. The value of the road system built by the timber sale is considered to equal the amount the NFF deposits were reduced. This amount is called Purchaser Credit.

TABLE III-26

TIMBER SALE COSTS

	1980	1981	1982	1983	1984	1985	1986	1987

1/ Does not include fuelwood volume.

As can be seen in Table III-27, returns and values are highly variable between years. This is a result of the forest industries reaction to market conditions and the high interest rates that occurred early in the decade. Logging activity is directly related to strength of the lumber market. This relationship is not as strong on the cost side. The timber sale program is based on an even-flow concept with annual sell levels balanced over a decade. This provides flexibility on a year to year basis while maintaining the long-term sustained yield. As a result of this concept, actual sell levels will vary somewhat each year in response to a variety of stimuli. The cost (budget) deviations are more related to Congressional and Administration efforts to manage the national economy consistent with the outputs available from the National Forest System.

Our present accounting practices do not provide for tracking the costs incurred in preparing a specific timber sale since these costs are spread over several fiscal years. The cost of a specific sale can only be estimated by using average costs determined by dividing the budget cost by the volume offered for sale that year. That results in

an average cost per thousand board feet (MBF) which is then multiplied by the sale volume. The result is an estimate of the sale cost. This cost can then be compared with the anticipated returns and values of the sale. This comparison will not provide a reliable picture of the individual sales cost/return relationship.

The cost of a specific sale will vary widely from the average based on the complexity of that sale. For example, if a sale is within an area that is visually sensitive, significantly more time and expertise is involved, hence the sale is more costly than a sale that is not in a visually sensitive area. Sales in unroaded area are significantly more costly than sales in areas that have been previously roaded. Also, sales that harvest small volumes of timber are generally more costly than sales that harvest large volumes. The return and value potential of a sale also varies widely depending on the timber species composition, logging systems needed to harvest the timber, mitigating work required of the purchaser, and the environmental constraints incorporated in the sale.

h. Local Wood Product Demand

The demand for wood products from the Wenatchee National Forest in the 1989-1999 decade is obviously difficult to predict. Such influences as the national economy, Canadian log imports, housing starts, exports to Pacific-rim countries, etc., are outside of regional and local control. Other more specific factors will, or could, affect the Forest's programmed harvest and the local wood products industry. These are the effects resulting from: rulings from "old growth" and "Spotted Owl" appeals and court decisions; significant changes in Congressional and Administration direction regarding budgets and targets (outputs); and delays or constraints from new emerging issues which undoubtedly will surface.

Certain localized situations will also have an effect. These include: the accelerated harvest of commercial timber on the private lands ("checkerboard" ownership) within the Forest by Longview Fibre, Boise Cascade, and Plum Creek Timberlands in the next ten years; the potential phase out of antiquated sawmills and the possible construction of new facilities; the continued sale of large volumes of timber by the Yakima Indian Nation from their reservation lands; and the continued close and intense scrutiny of many Forest Service projects by local publics. The various factors influencing the demand for wood products are often conflicting.

The past demand for logs from the Wenatchee as evidenced by the long-term average cut is about 168.6 million board feet per year. During this same period, the sell volume target was 175.9 million (MM) board feet per year, and the average sell was 173.3 MM board feet. See Table III-28. The Forest has an uncut timber volume under contract (as of October 1988) of 370 MM board feet. This is a significant reduction from the 850 MM board feet under contract in 1985. This reduction is due to the Timber Relief Act, increased demand, reduced stumpage values, and reduced timber supply. Although some Forest offerings in 1989 did not receive bids, an increase in demand is evidenced by the decreased volume under contract.

Future demand is likely to increase above the historic 168 million due to the decreases in supply from the adjacent west side Forests.

VEGETATION-TREES

It has been a long accepted practice to have about two years of programmed harvest under contract. For the Wenatchee, this would be about 372 MM board feet. The remaining volume is available to sell until the new Forest Plan is approved and implemented. Obviously, the previously mentioned budgets, appeals/litigation, etc., will have their influence for most of the decade.

The accelerated harvest of timber from private lands is affecting, and will continue to affect, the demand for timber from the National Forest. Both Longview Fibre and Plum Creek export a significant amount of their logs to the Pacific-rim countries. The pine, smaller logs, and logs which are not "marketable" to export customers at a particular time, are generally sold locally to some of the same purchasers who rely on National Forest timber. The greater the harvest of the major private landowners, the greater is the supply of logs to others. It is very reasonable to assume their activity will continue at a high rate during the decade. The effect of the high private industrial harvest currently occurring and the downward projection on the second decade is shown on Table III-29.

In addition to the private landowners, the Yakima Indian Nation will continue to make timber readily available to traditional purchasers of National Forest timber. The Yakimas have harvested heavily in the Yakima Basin and are major suppliers of timber to local industry. Bureau of Indian Affairs volume for eastern Washington is estimated to be 479 MM board feet. This is down approximately 50 MM board feet from harvested volumes of the past decade (Larson, 1982). The Washington Department of Natural Resources (DNR) proposed volume from Eastern Washington is 87 MM board feet annually thru 1993 (DNR, 1983). If stumpage prices increase, there exists a strong potential of an increase in yield from other private lands. As shown in the following table, the Department of Natural Resources projects a strong increase in volume from other private lands that may equal the decreases in forest industry and public timber supplies.

Much of the potential increase from private lands is small diameter timber located in NE Washington Counties and not volume immediately adjacent to the Wenatchee National Forest in Chelan, Kittitas and Yakima counties.

1/ Inventory for timber 40 years old and older

Because of the long distances to major pulp and paper facilities, demand for low quality and small size material has historically been low. Under the 1963 Wenatchee Working Circle Plan, these materials were not counted in calculating the proposed harvest. Since 1963, new industries utilizing smaller logs have been installed in Entiat, Cashmere, Yakima, Ellensburg and Naches.

The Forest has spent a great deal of time and money to dispose of logging and other residues for the purpose of minimizing fire hazard, preparing planting sites, and making cutting activities more acceptable visually. In recent years, the demand for pulpwood and firewood have helped reduce the amount of residues by about one-third, but the Forest still has a large program for disposal.

During the summer of 1984, a marketing specialist position was created and filled for the purpose of helping to dispose of the remaining residues. This is an area position for the Olympic, Mt. Baker-Snoqualmie, and Wenatchee National Forests. During this past year, our marketing specialist has identified several residue utilization opportunities including California and Asian markets where prices for residues are generally much higher.

Current central Washington mill capacity is 314 MM board feet. Historically such mills rely on the Wenatchee National Forest for approximately 60 percent of their production. This dependency by individual mills ranges from 40 percent to 100 percent (telephone survey, Walk, 1985). Higher prices for quality timber at west side mills often results in the best quality logs being transported to the Puget Sound area. In addition to the log supply for central Washington, a 1980 mill survey found over 13 MM board feet from the Wenatchee going to Puget Sound area mills annually (Socio-Economic Overview, 1982).

In summary, the best estimate of the future demand for wood products appears similar to the harvest level during the past decade or higher. There are no indications that there will be a surge of new mill capacity developed in the area, but decreased supply from adjacent westside Forests may increase prices and demand outside the local area. Any changes in mill facilities will likely be a replacement of antiquated operations with state-of-the-art mills. The exception would likely be the increased utilization and marketing of lodgepole pine. The significant amounts of timber volume available from Longview Fibre, Boise Cascade, and Plum Creek lands, as well as continued sales from the Yakima Nation, should make

timber supplies readily and competitively available for the first decade. It appears that the second decade is when demand may increase significantly due to decreased large industrial timber. Without major silvicultural investments in all land ownerships and a decrease in conversion to non-forestry uses, it appears the supply/demand gap will increase in future decades.

i. Cumulative National Forest Supply Outlook

1) Supply:

Four factors have a major influence on the supply of sawtimber in northeastern Washington. They are: a) acres of suitable timber land available for timber production; b) intensity of silvicultural practices; c) working group and productivity class; and d) management direction.

The past and projected sawtimber supply from the major institutional suppliers is shown in Tables III-29 and III-30.

Based upon the Allowable Sale Quantity (ASQ) in the preferred alternatives, timber available for harvest from National Forests in northeastern Washington will approximately equal volumes sold during the past decade and slightly exceed sawtimber actually harvested. However, the proposed ASQ represents a decline of 16% from the programmed harvest under existing timber management plans. Local availability of National Forest sawtimber will change substantially. Supplies of National Forest timber will increase in the Colville area, while supplies will decrease in the Okanogan and Wenatchee areas. There will also be a shift in species from mixed conifer to more lodgepole pine on the Okanogan National Forest. All Forests show a decline in available old-growth ponderosa pine, and increased numbers of smaller diameter trees.

Table III-31

COMPARISON OF OUTPUTS FROM OKANOGAN, COLVILLE, AND WENATCHEE NATIONAL FORESTS
(Million Board Feet per Year)

	<i>Existing TM Plan Potential Yield 2/</i>	<i>Programmed Harvest</i>	<i>10-Year Average 3/ Offered 1/ Sold Cut</i>			<i>FEIS Preferred ASQ 4/</i>	<i>Max Timber Benchmark</i>
Okanogan NF	93	87	80	73	61	69	107
Colville NF	115	115	94	78	78	118	247
Wenatchee NF	177	177	192	172	162	136	211
Total	385	379	366	323	301	317	565

TM = Timber Management
ASQ = Allowable Sale Quantity

1/ Sell target from attainment reports.

2/ Post 1984 Washington Wilderness Act. Prior to passage of the Act, the programmed harvest level for the three Forests was as follows: Colville National Forest 115 MMBF, Wenatchee National Forest 189 MMBF, and Okanogan National Forest 92 MMBF.

3/ Based upon FY 1977 - 1986 data Chargeable volume only. Non-chargeable estimated for "Cut". Data from timber sale cut and sold reports Colville National Forest data available shows no non-chargeable harvest Chargeable cut estimated from proportion of non-chargeable in sold volumes.

4/ Okanogan National Forest data for ASQ taken from the Okanogan plan DEIS.

Public demand for firewood permits increased rapidly on the Forest from 1973 through 1981. Introduction of a charge permit system in 1982 resulted in a temporary decrease in permits. However, in 1984 nearly 10,000 permits were sold, an 8 percent increase over 1983. Income in 1984 from wood permits (four cords for \$10, with a 10 cord maximum) was \$119,745.

j. Regional Timber Supply and Projections

The principal projections used in developing long-range plans and programs for management of the National Forests are contained in the Forest and Rangeland Renewable Resources Planning Act (RPA) Assessment and 1984 Update (USDA, 1984). These projects focus on the situation for the long term (50 years) and do not necessarily recognize current short-term regional fluctuations. A summary of the projected RPA trends (year 2030) for timber supplies follows.

1.) Hardwoods

The current balance between growth of wood and its removal shows that hardwood forests and eastern softwood forests can support additional timber harvests. However, this balance will change, and future harvests, particularly in the decade beyond 2000, could vary over a wide range. Nonetheless, if commercial timberland owners continue to respond to price and inventory changes, then timber harvests can be increased substantially during the next few decades. The largest hardwood increase will be in the South, with an increase of 6.0 billion cubic feet in 2030 (USDA, 1984).

2.) Softwoods

Total projected softwood harvest would rise 24 percent from 1980 to 11.9 MMCF per year by 2030. There are important differences among the major softwood timber producing regions. In the Douglas-fir subregion, projected annual harvest from 1980 to 1990 is about 2.3 MMCF per year, then declines to about 2 MMCF per year. This level is roughly maintained through the rest of the 50-year projection period.

In contrast, the other major source of softwood timber harvest is the South, which is projected to rise from about 4.1 MMCF in 1980 to 7.3 MMCF per year in 2030. However, most recent forecasts are now showing a downward modification in the rate of economic supply. This may indicate that the South could be expected to be shifting to a slower rate of increase above present levels until the year 2030. Much of the expansion in the South with softwoods, as well as hardwoods, is due to the fact that its wood products production has become more diversified as compared to other regions of the country.

3.) Short-Term and Long-Term Demand Trends

Over the next ten years, timber demand for the Pacific Northwest geographic region will grow slowly. Although there is a backlog of unfulfilled housing demand, the future will depend primarily on the continuing strength in personal income and the availability of affordable housing and financing. In addition, projections of exports to the Pacific Rim countries show a continuing slow economic growth. The analysis acknowledges there will be a declining trend in the construction sector. Structure replacement, rather than new constructions, will characterize the housing market. Projections for increase in demand may be described as considerably restrained and cautious (Nomura, 1981).

Evaluation of recent data and information indicates that the demand for timber is changing to a moderate rate of increase as compared to the slowdown that occurred in the early 1980's. The ability to sustain this increase is linked to the *critical issue of costs*. The short-term future of timber and wood products demand is clouded by the severity and length of the housing and wood products recession that began in 1980.

The long-term trends in housing demand, the growing popularity of construction methods that use less wood, the availability of wood substitutes, and a shift in business management strategies all contribute to a potential shift in future demand (Adams and Haynes, 1985).

Wood supply will continue to be an issue because it will be highly dependent on the ability of producers to lower costs to be competitive with wood substitutes (Schallau, 1986). Although overall current timber supply levels in the Pacific Northwest Region may be capable of meeting future demand, the shifting of industry within the region, the shifting emphasis on the types of wood products produced, and the ability of the subregion to supply the various kinds of wood needed are subregional problems.

An effort by the wood products industry to broaden the economic base may enable the Pacific Northwest to regain much of its previous economic strength; this will take time. The opportunity to increase exports to international markets by modernizing facilities, adopting state-of-the-art technology, reducing costs, and diversifying into other sectors of production (similar to what the South has done) could help to rebuild and stabilize the wood based sectors of the region (Schallau, 1985).

4.) Private and Public Land Interrelationships

Currently, part of the timber formerly supplied by the Pacific Northwest Region is being supplied by the South and Canada. However, the situation with Canada can be expected to change as there are indications that the economic supply may begin dropping off within 6 years, or at least by 15 years. The projected change indicates a potential drop in supply capability of 30 to 50 percent from the current relatively high levels. The South should be able to maintain or show a slow increase in harvest because of its remaining inventory and some substitution of hardwoods. However, both the economic and physical supply of softwoods from that area may begin to show a decline by the year 2030.

At about the same time this drop in supply capability begins to occur for the other sources, the growth of wood fiber on private lands in the Pacific Northwest would again be increasing its capability. The private lands in the Pacific Northwest could then become a major source of supply for softwoods to meet National and international demand. Further, during the period before the private lands in the Region regain their full supply

potential, the public forests would be looked upon as a major source for a relatively stable supply of wood fiber (Schallau, 1986).

The demand for timber harvest in the area surrounding the Wenatchee National Forest is assumed to be infinitely elastic. This means any increase or decrease in local timber supply will not affect long-term price trends which are determined by the prevailing market conditions such as mortgage rates, strength of the U.S. dollar, and other factors at the National and regional level.

A broader vision of the future that includes developing a flexible regional basis for stabilizing wood supplies and a forward looking perspective on wood fiber management, will also allow the Pacific Northwest region to better utilize the opportunity to increase exports to international markets. To achieve this, the forest products industry will need to learn the workings of a different market system and provide more products in the form demanded (Campbell, et al., 1983). In addition, actions by industry, such as modernizing facilities, adopting state-of-the-art technology, reducing costs, and diversifying into other sectors of production, similar to what the southern region of the country has done, could help to rebuild and stabilize the wood-based sectors of the region (Schallau, 1985).

9b. VEGETATION: OLD GROWTH

Old growth is typically thought of as a plant community made up of very large trees and other related vegetation that has no visible evidence of human activities and may be several hundred years old. There are areas of old growth like this on the Wenatchee National Forest. However, characteristics of old growth vary with site potential and much of the forest land on the Wenatchee probably has never supported the awe-inspiring stands commonly equated with old growth. Agreement on a common definition of old growth is difficult to achieve because each individual site has its own potential to produce old stands with characteristics that are unique. However, there are some attributes of old-growth stands that can be addressed in a general way.

The Pacific Northwest Region of the Forest Service defines old-growth forests as having: (1) Mature and overmature trees in the overstory that are well into the mature growth stage; (2) a multi-layered canopy and trees of several age classes; (3) standing dead trees and down materials are present; and (4) evidence of man's activities may be present, but do not significantly alter the other characteristics (Pacific Northwest Regional Guide).

Because there are numerous types of old growth it is not possible to present definitive descriptions for each site. It is possible to present some general characteristics typical of "dry" forested sites and "moist" forested sites. On the Wenatchee, dry forest includes those stands within the ponderosa pine, Douglas-fir, and perhaps the marginal grand fir series sites. Moist sites generally are those characterized at climax by the dominance of Pacific silver fir, western hemlock, grand fir, subalpine fir, and western redcedar. Other marginal forest sites at very high elevation, although "moist" and often dominated at climax by subalpine fir (and other harsh site adapted species), are not described.

From the Forest Service Pacific Northwest Regional Guide:

The dry site stands contain at least 10 mature to overmature trees (21 inches or more in diameter) per acre with ponderosa pine or Douglas-fir representing 75 percent of the overstory canopy. On each acre, a minimum of two standing snags will be present with at least 1.5 tons of down material, including 3 logs.

The moist site stands include both shade tolerant and intolerant tree species. These stands contain at least 15 trees per acre (21 inches or more in diameter), and each acre will have 2 snags with at least 3 tons of down material including 3 logs. Broken-topped trees may be present.

The Forest has completed several old growth surveys. Different criteria were used in each case and there was only a small amount of ground verification. Consequently, the amount of old growth on the Forest can only be estimated. The estimates indicate that there are 319,000 acres of old growth on the Wenatchee National Forest, of which 148,000 acres are in wilderness, 70,000 acres are outside of wilderness but not available or are unsuitable for timber production in existing plans, and 101,000 acres are outside of wilderness but available and suitable for timber production in existing plans.

Most old growth is found in wilderness or unroaded areas. It extends from Rimrock Lake north to Lake Wenatchee in scattered parcels ranging in size from five acres to several thousand acres. Low elevation areas that have been readily accessible to timber harvest historically, have few old-growth stands. Generally, old-growth stands have supported high timber volumes and have often been targeted for harvest. Consequently, the amount of old growth has been in decline for many years.

The future of old growth on the Wenatchee is in debate. Some publics feel that all remaining old growth should be preserved while other publics would like to continue harvest of old-growth stands. The Forest Service realizes the need for the preservation of old growth for biological diversity, wildlife, and plant habitat and for aesthetic reasons. Spotted owls, pileated woodpeck-

ers, and pine martens are management indicator species that require old growth and mature forest habitat. Spotted owl areas will not be harvested and pileated and marten areas will be managed under a long rotation strategy. Other areas will be set aside strictly for the maintenance of diversity, aesthetics, or for species habitat. For the next decade, the wilderness areas, unroaded areas, and the management indicator species areas (especially spotted owl areas) will be where the majority of old growth remains.

9c. VEGETATION: FORAGE

a. Overview

The vegetative types within the Forest environment have evolved through the natural interactions of grazing animals and wildfire occurrence. Fire removed or thinned the tree vegetation while large grazing animals used and modified the resulting forage resource. This interaction has provided a wide diversity of vegetation and wildlife. Grazing of vegetation by large wildlife species such as elk modified the forage. It also retained some types in successional stages beneficial to use by deer, mountain sheep, and many small game and non-game species.

Forage for grazing animals is present throughout the Wenatchee National Forest as a component of all vegetative types. These vegetative types can be combined into the following four zones:

1) Grass-Shrub

The lowest elevation, driest habitat is a combination of vegetative community types with plants such as sagebrush, bitterbrush, and bunchgrasses. Although thought of as a low elevation type, the grass-shrub zone can occur on dry south aspects up to 6,000 feet in elevation. Balsam root, creeping phlox, mariposa, and rock lilies color these open areas in early spring.

2) Dry Forest (Ponderosa Pine/Douglas-fir Climax Forest)

The low elevation, dry non-forest zone gradually changes to the ponderosa pine/Douglas-fir zone with increasing elevation and moisture. A mixed ponderosa and Douglas-fir stand is the most common situation but pure stands of pine or Douglas-fir occur occasionally on small areas. Pinegrass, elk sedge, wheatgrass, ceanothus, bitterbrush, serviceberry, and ocean spray are some of the common understory plants under the older stands.

3) Moist Forest (True Firs, Hemlock, Cedar, and Spruce Climax Forest)

The moist forest zone is characterized by a wide variety of plant species. Douglas-fir and ponderosa pine may be present, but without disturbance it will gradually be replaced by shade tolerant grand fir, silver fir, western hemlock, or western red cedar which are all important components of a typical wet forest habitat. Elk sedge, pinegrass, and many brush species are common understory plants. These plants provide forage primarily after timber harvest or fire removes the tree overstory.

4) Sub-Alpine Parkland and Mountain Meadows

This zone is best known for its wide variety of flowering herbs and forbs. Parklike stands of whitebark pine, Englemann spruce, subalpine fir, and alpine larch adjoin the barren or treeless upper mountain slopes. Many grasses, sedge, and shrub species provide some of the highest producing forage areas on the Forest. However, due to the short snow-free season, they are available to use for only a short duration.

The total annual forage production on the Forest is estimated to be 336,000 tons. One-third, or 112,000 tons, are located on steep slopes and only 10 percent of this production is considered available to wildlife only. Of the remaining 224,000 tons, reductions are made for plant survival and soil and watershed protection. The total amount available to wildlife and livestock is 65,000 tons or 130,000 Animal Unit Months (AUM). An Animal Unit Month is considered one cow with calf grazing for one month, which requires approximately 1,000 pounds or one-half ton of forage. In 1988, there were 20,900 AUMs used by livestock which allowed 109,100 AUMs for wildlife.

b. Livestock Management

The management of rangelands on the Wenatchee National Forest involves the use of livestock as a tool to manage the non-tree vegetation. When the management of range vegetation is approached in this manner, there is a substan-

tial opportunity to use livestock grazing to enhance other resource objectives. Cover and forage can be manipulated to improve habitat for wildlife. Vegetative competition with trees can be reduced, or vegetative cover increased to protect soils and improve watersheds. The relationships between range management and other resources and land uses are discussed in more detail later in this section.

Of the 2,164,180 acres within the Forest, 18.5 percent, or 401,100 acres, is within vegetation types and on slopes suitable for grazing by livestock. There are an additional 500,871 acres outside of wilderness potentially capable of providing livestock forage following silvicultural practices such as regeneration harvests or thinning.

Current inventoried range allotment boundaries do not include all of the available and suitable range resource on the Forest (see Table III-32). There are 40 allotments for cattle and sheep grazing under permits to livestock owners dependent on forage to balance their year-long operation. Another 36 allotments are available to the recreation livestock owners. These inventoried allotments contain approximately 203,500 acres of suitable range, or 51 percent of all suitable range on the Forest. The annual grazing capacity is estimated to be 23,210 Animal Unit Months (AUMs) on the 40 commercial livestock allotments and 4,307 AUMs on the recreation livestock allotments. When grazing opportunities outside these allotments are considered, the total annual grazing capacity for the Forest is estimated to be 37,031 AUMs under existing management strategies. Overall range condition on commercial grazing allotments is considered satisfactory. Most ranges are in good condition. The overall trend in range condition is considered either up (45%) or static, but is not in a downward trend.

Past use by livestock on the Forest was much more extensive than it is today. There is little of the existing suitable range that was not used historically to some extent. The high country provided grazing for sheep in numbers greatly exceeding today's use, while the lower rangelands provided horse and cattle grazing to the hundreds of homesteaders located in or near the Forest boundaries. This heavy use did have an impact on

VEGETATION. FORAGE

the vegetation, soil, and water resources. As grazing was brought under management, the emphasis was to reduce animal numbers and spread out use with salting and herding. At the same time, managers sought to provide the forage to produce red meat and help stabilize the agricultural community.

It has only been in the past 10-15 years that intensive grazing systems have been developed on the Forest using fencing and rotation of use seasons, which has improved the vegetation, soil, and water resources. Most of the real or perceived resource conflicts and competition between grazing and other resources has been a result of past use and management practices. More recently range scientists and resource managers have begun to understand and use livestock as a total resource management tool.

Because of the introduction of intensive management systems there are no problem allotments on the Forest with widespread unacceptable resource damage. A few do have relatively small problem areas where cattle concentrate, resulting in over use, soil compaction, or competition with wildlife. Two examples include the Table Mountain Allotment, where there is some competition for space during elk calving season, and Manastash Allotment where cattle concentrate in the drainage bottoms.

Management practices occurring on the Forest in addition to administration of the permit and allotment management systems include: construction of structural range improvements, control of undesirable plants, and seeding and fertilization of deteriorated rangelands. These practices are necessary to maintain or improve the condition of the forage resource. Existing structural improvements include 112 miles of fence, 152 spring developments with 8 miles of pipeline, 52 cattle-guards, and 7 holding corrals.

TABLE III-32

SUITABLE RANGELANDS 1/ AND ANIMAL UNIT MONTHS AVAILABLE TO LIVESTOCK 2/

	Number of Allotments	Suitable Rangelands (Acres)	Percent of Suitable Rangelands	Percent of Total National Forest Acres	Estimated Livestock Grazing Capacity (AUM)	1988 Actual Use (AUM)	1988 Livestock Numbers
Inventoried Commercial Livestock Allotments (Cattle, Sheep, and Horses)	40	182,742	45 5%	8 4%	23,210	18,499	1,984 Cattle 8,607 Sheep 87 Horses

Sub Total in Allotments	76	203,461	50 7%	9 4%	27,517	20,876	---
Suitable Range Outside Inventoried Allotments and Outside Wilderness	---	197,639	49 3%	9 1%	9,514	---	---
Total Forest	76	3/ 401,100	100 0%	18 5%	37,031	20,876	---

1/ Suitable Rangelands are those areas currently producing forage suitable for livestock use on lands less than 60 percent slope.

2/ Animal Unit Month capacities are for livestock only Total production in pounds per acre have been reduced to reflect needs of wildlife, soil, and watershed protection, in addition to the plant needs

3/ There are an additional 500,871 acres outside of wilderness that have potential to contribute to the suitable rangeland base after timber has been harvested

c. Livestock Forage Demand and Supply

Assumptions and methodology of projecting future demand are contained in the 1985 Draft RPA Assessment. The demand for range grazing nationally is projected to increase above current levels. In the Pacific Northwest, the demand is expected to increase 50 percent by the year 2000 (Pacific Northwest Regional Guide). The "Wenatchee National Forest Socioeconomic Overview" discusses the difficulty of projecting demand due to past variability of the livestock industry. However, it estimates the demand for grazing on the Forest will increase one to two percent per year over the next ten years. Although estimates of the amount of increase in demand may vary by source document, all agree that there will be an increase in demand for livestock forage from all sources, including grazing from National Forest lands.

Applications for grazing cattle on the Forest is expected to be higher than the supply. Permitted use, however, is expected to remain below the biological potential because:

- (1) Twenty to 30 percent of the potential is sheep range which is unsuited to cattle and significant increases in sheep grazing are not expected.
- (2) A high investment is required by both the permittee and the Forest Service before the forage can be made available for use by cattle.
- (3) There is a high potential for increased grazing capacities on private range lands.

Demand for cattle grazing is expected to be greater than the one to two percent projected increase, particularly after the first decade.

The demand for sheep forage is more difficult to project. National demand is down and this trend is expected to continue indefinitely. Locally permitted numbers on the Forest have fluctuated year to year over the past six years. Based on the Five Year Grazing Statistical Report, sheep numbers were down slightly between 1975 through 1980. However, numbers for 1984 were higher than the 1975 level. The demand for sheep grazing on the Forest is expected to remain at or slightly above current levels for the next ten years.

The most extensive range grazing opportunities are on the more than one million acres of private range and pasture land in Chelan, Kittitas, and Yakima Counties. The 2,990 head of cattle permitted to graze on National Forest lands represent less than 2 percent of the number of head tallied in the 1982 Census of Agriculture Preliminary Reports for those Counties. The 8,800 sheep represent approximately one half of the total tri-county sheep population.

The total permitted grazing use is not expected to exceed 36,000 AUMs annually by the fifth decade. A 2,000 - 4,000 AUM increase per decade over the next five decades is anticipated.

There have been between 15,100 and 20,500 Animal Unit Months actually grazed on the Forest over the past 5 years. The forage for livestock is provided from suitable rangelands through grazing permits to 37 local livestock owners. These permittees are dependent on the forage for spring, summer, and/or fall grazing to balance their year-long operations. Although the Forest grazing represents less than two percent of the number of head grazing in the three county area, the privilege to graze is important to the individual permittees. To many of these permittees, grazing provided by the Forest represents all or most of the grazing resource they have available and loss of this resource would force many of them out of business.

Supply is expected to exceed permitted use through five decades which will allow resolution of resource conflicts, and also offer an opportunity to utilize livestock to enhance other resource objectives. Intensively managed livestock will be used to improve and increase wildlife forage. Reforestation problems with competing vegetation will be reduced through use of grazing management systems, while timber management on commercial forest land will contribute to the livestock forage base (transitory range).

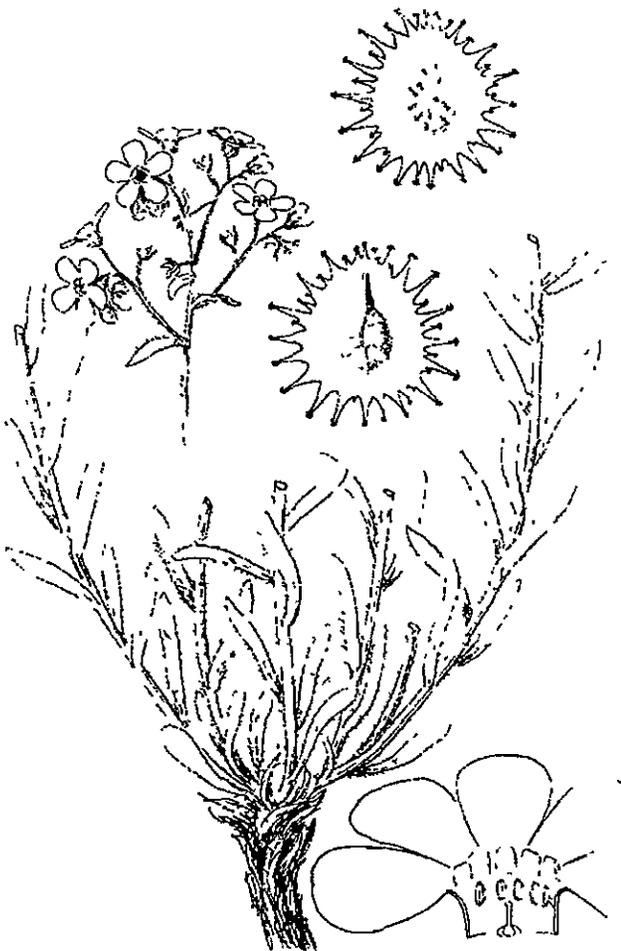

There are threats and hazards that have the potential to diminish the supply or reduce the quality of the range resource. These include the occurrence and invasion of undesirable plants and insects and funding levels less than necessary to implement and monitor high quality resource management systems.

9d. VEGETATION: UNIQUE ECOSYSTEMS

The Tumwater Botanical Area was established under Regulation T-9(I) on June 10, 1938, for the protection of the plant Lewisia tweedyi. The 1,104 acres was redesignated in 1971 as a Botanical Area under 36 CFR 251.22 to be managed in a near natural condition to protect plant species which occur there.

Although the area is located along a major highway, it is rather inaccessible due to the steep, rugged terrain. It is usually visited only by people who wish to view or study the Lewisia tweedyi. The area lays within sections 28 and 34, T.25N., R.17E., and is approximately four miles north of Leavenworth, Washington, in the Tumwater Canyon.

The objective of the botanical area is to maintain a natural ecosystem. This precludes activities such as timber harvest, heavy recreation use, prescribed fire, and grazing.

9e. VEGETATION: SENSITIVE PLANTS

The Forest has a large variety of unique plant species. These species represent habitats and plant communities which have developed as a result of various geological processes. The Wenatchee Mountains, in the upper reaches of the Teanaway drainage, have the most extensive serpentine outcrops in Washington. These serpentine soils support unique plant life that is different than other soils.

Also, portions of the Forest along the east and southern margins were not affected by the continental ice sheet. In these areas mountain tops and some valleys escaped glaciation. As a result, one of the highest concentrations of unique endemic plants in Washington occur in the mountains near Wenatchee.

There are no known Federally listed threatened or endangered plant species on the Forest.

There are 34 plant species on the Forest that are on the Region 6 sensitive plant list (Table III-33). Of the 34 species, 4 are candidates for Federal listing and the remaining 30 are listed by the State of Washington. The extent of the populations of these species on the Forest is unknown.

Before a project is initiated, inventories for populations and distribution of threatened, endangered, and sensitive species will be conducted on a priority basis.

TABLE III-33
SPECIAL PLANT SPECIES IN THE WENATCHEE N.F.

LIST OF SENSITIVE SPECIES

Date Last Revised 5/23/88

PLANTS

<u>Scientific Name</u> common name	Status 1/	Occurrence 1/
<u>Agoseris elata</u> tall agoseris	RF - S	D
<u>Anemone nuttalliana</u> pasque flower	RF - S	D
<u>Astragalus arrectus</u> Palouse milkvetch	RF - S	D
<u>Antennaria parvifolia</u> Nuttall's pussy-toes	RF - S	D
<u>Botrychium lunaria</u> lance-leaved grape-fern	RF - S	S
<u>Botrychium minganense</u> Victorin's grape-fern	RF - S	D
<u>Botrychium montanum</u> mountain moonwort	RF - S	D
<u>Calamagrostis tweedyi</u> Cascade reedgrass	Cat. 2	D
<u>Carex bauxbaumii</u> Bauxbaum sedge	RF - S	D
<u>Carex camosa</u> bristly sedge	RF - S	D

1/ Key to Abbreviations Used Above

Federal Candidate Species

Cat. 1 = Category 1 Species (US Fish and Wildlife Service has enough information to support the appropriateness of proposing the species to the list of Endangered or Threatened species)

Cat. 2 = Category 2 Species (Needs further information to confirm the appropriateness of proposing the species to the list of Endangered or Threatened species)

Cat. 3 = Category 3 Species (No longer being considered for listing as Endangered or Threatened and are not regarded as candidate species:

a. Taxon extinct

b. Not a taxonomic entity

c. Taxon more abundant and/or widespread than previously thought and/or not subject to any identifiable threat)

RF - S = Regional Forester Sensitive Species

D = Documented occurrence

S = Suspected occurrence

9f. VEGETATION: RESEARCH NATURAL AREAS

Research Natural Areas (RNA's) are part of a Federal system of such tracts established for non-manipulative research and educational purposes. Each RNA is a site where some features are preserved for scientific purposes and natural processes are allowed to dominate. Their main purposes are to provide: (1) baseline areas against which effects of human activities can be measured; (2) sites for study of natural processes in undisturbed ecosystems; and (3) gene pool preserves for all types or organisms, especially those which are classified as rare and endangered types.

Prior to establishment, a comprehensive formal report is made. For RNAs proposed on National Forest System lands, the report is submitted to the Chief of the Forest Service for approval.

Established RNAs

There are two established RNAs on the Forest. Meeks Table RNA on the Naches Ranger District is 64 acres in area and represents the ponderosa pine/pine grass plant community with a co-dominance of Douglas-fir. It was established on July 7, 1948, and is now within the William O. Douglas Wilderness.

Thompson Clover RNA located in Swakane Canyon on the Entiat Ranger District is 276 acres in size and exemplifies a plant community characterized by Thompson clover. It was established on February 17, 1977.

Formally Proposed RNAs

The Research Natural Area Committee for the Pacific Northwest has formally proposed two additional RNA's. Eldorado Creek located in the Teanaway drainage of the Cle Elum Ranger District is 1,336 acres in size and represents a plant community found on serpentine soils. The Eldorado Creek area was designated as a Special Area (Proposed RNA) in the Alpine Lakes Management Plan (November 2, 1981).

Fish Lake Bog on the Lake Wenatchee Ranger District is a 106 acre area on the west end of Fish Lake near Lake Wenatchee. This represents a floating bog community.

Preliminary reports have been made for both of these areas, Fish Lake Bog on July 5, 1979, and Eldorado Creek on August 9, 1972. A supplemental report on the mineral character of the proposed Eldorado Creek RNA was made on November 6, 1974.

Recommended RNAs

The Research Natural Area Committee for the Pacific Northwest Region determined that the candidate RNAs listed in Table III-34 represent the best examples of particular kinds of natural ecosystems in the Region and are needed to meet present and future demands. There may be some future RNA needs that can best be satisfied on the Wenatchee National Forest. When suitable new areas are identified, they will be considered for addition to the Research Natural Area inventory.

TABLE III-34
RECOMMENDED RESEARCH NATURAL AREAS
1984

Name	Area (Acres)	Location (District)	Plant Community Exemplified
* 1. Cedar Creek	2205	Naches	Mixed old-growth conifer/shrub forest and Pacific silver fir forest.
** 2. Icicle/Frosty Creek	784	Leavenworth	Western red cedar/western hemlock forest.
** 3. Chiwaukum Creek	1124	Leavenworth	Grand fir mixed old-growth conifer/shrub
4. Drop Creek	530	Cle Elum	Englemann Spruce/Subalpine fir forest
* Within the William O. Douglas Wilderness		** Within Alpine Lakes Wilderness	

Steps in Establishment of RNA's:

1. R-6 Research Natural Area Committee working in conjunction with the Washington Natural Heritage Plan (Department of Natural Resources, 1985) identifies the need for a site representing a specific natural ecosystem.
2. This committee then works with the area ecologist and ranger district personnel to identify several potential representative sites.
3. The committee visit and evaluates the sites and narrows the list down to the most representative site.
4. This site is then recommended through the Forest Plan for establishment as an RNA.
5. If the area is allocated as a proposed RNA by the alternative in the Forest Plan which is implemented, then an establishment report is developed. In the past, ranger district personnel have worked with personnel from the Pacific Northwest Forest and Range Experiment Station in the development of this report.

6. The approval procedure for an RNA Establishment Report is as follows:

- District Ranger - Review and Recommend
- Forest Supervisor - Review and Recommend
- Pacific Northwest Station Director - Review and Recommend
- Regional Forester - Review and Recommend
- Director of Division of Recreation - Review and Recommend
- Deputy Chief of Research - Review and Recommend
- Chief, U.S. Forest Service - Approve

7. Upon approval by the Chief, the area is designated as a Research Natural Area and will be managed accordingly.

**9g. VEGETATION: ENTIAT
EXPERIMENTAL FOREST**

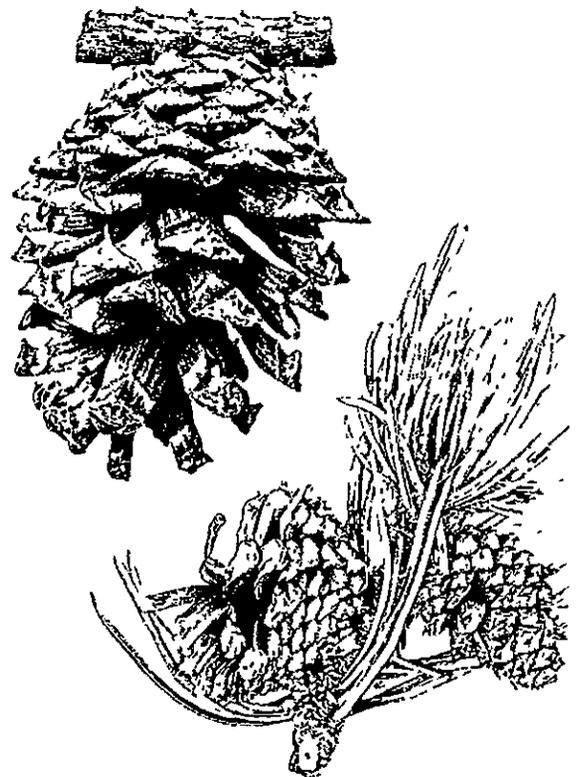

The Entiat Experimental Forest includes 4,770 acres of forest lands located within the Entiat River drainage northwest of Wenatchee, Washington. Research has been conducted on the area since 1957; in 1971, it was formally designated as an Experimental Forest. The Pacific Northwest Forest and Range Experiment Station and the Wenatchee National Forest cooperatively administer the area with the primary goal of providing opportunities for studying the effects of forest management and fire on vegetation, soil, and water resources. The area was selected as being representative of steep, forested watersheds occurring along the east slope of the Cascades. It consists of three similar, contiguous watersheds ranging in size from 1,168 acres to 1,393 acres and in elevation from 1,800 feet to 7,000 feet. Mean slope is 50 percent ranging up to 90 percent.

Geology, soils, climate, and vegetation in the Experimental Forest are representative of the surrounding Wenatchee National Forest. Parent materials are granitic with much evidence of glaciation at lower elevations. Overlying deposits of volcanic ash and pumice from Glacier Peak eruptions have significantly influenced soil development. Climate is characterized by moderately cold, wet winters and hot, dry summers. Precipitation averages 22 inches, occurring mainly as snow between November and May.

A major wildfire which burned most of the area in 1970 has had a dramatic impact on Forest vegetation. Pre-fire vegetation was primarily undisturbed, mature forest with small, subalpine grass-forb openings and bare rock. About 75 percent of the forest was classed as ponderosa pine, with Douglas-fir the main associated species. Thickets of dense lodgepole pine occurred on wetter sites at higher elevations. Important understory species included bitterbrush, snowbrush ceanothus, pinegrass, and numerous forbs. Fifteen years after the fire, the vegetation consists of a mosaic of shrub fields intermixed with planted pine and fir, and dense, young stands of naturally-established lodgepole pine. Scattered remnants of unburned old-growth forest occur on rocky ridges and outcrops.

The original research plan for the experimental watersheds was to develop baseline information on climate and hydrology under natural conditions, then test for changes following the construction of roads and implementation of several timber harvest practices. The collection of this information and the preparation of harvest plans were nearly complete when the watersheds burned.

Fire is a common occurrence in this forest, hence research objectives were quickly changed to utilize the preburn data to evaluate effects of fire on the environment and the alteration of those effects by the re-establishment of forest vegetation. Initial postfire studies provided land managers, resource specialists, and scientists with a better understanding of: the hydrologic response of burned watershed including water yield and physical water quality, chemical water quality and site productivity in response to wildfire and erosion control fertilization; natural vegetation recovery and the effectiveness of erosion control seeding and fertilization treatments; soil and water responses to several methods of timber salvage; and effects of a large wildfire on local and regional economics.

10. WATER

a. Overview

The Wenatchee National Forest is an extremely important source of high quality water for all types of uses. The water produced on the Forest maintains components of the natural ecosystem, including vegetation, fish, and wildlife. Water also serves the administrative needs of the Forest Service and is used both on and off Forest for domestic, municipal and industrial purposes, stock watering, irrigation, power generation, and recreation.

The majority of the Forest lies within four sub-basins of the Columbia River Basin: the Chelan, Entiat, Wenatchee, and Yakima Rivers. There are an estimated 3,600 miles of perennial streams on the Forest, with 806 miles and 963 miles of Class I and II streams, respectively. The Forest contains hundreds of lakes, ponds, and springs that receive a variety of uses. There are an estimated 57,000 acres of lakes and reservoirs on the Forest. The following table lists the 25 major watersheds on the Forest and the sub-basins to which they belong.

**TABLE III-35
WATERSHEDS OF THE WENATCHEE NATIONAL FOREST**

SUB-BASIN	WATERSHED	TOTAL ACRES	PRIVATE ACRES	WILDERNESS ACRES (NET)
Chelan	Stehekin River	91,097	0	91,097
Chelan	Lake Chelan	285,079	7,462	110,517
Entiat	Entiat River	174,202	9,095	25,398
Wenatchee	Chiwawa River	119,188	4,918	37,652
Wenatchee	White, Little Wenatchee R.	173,354	5,745	105,407
Wenatchee	Nason Creek	68,752	14,904	19,335
Wenatchee	Wenatchee River	160,676	45,771	30,337
Entiat	Mad River	61,035	5,851	0

Yakima	American River	50,838	212	39,708
Yakima	Bumping River	71,529	148	53,743
Yakima	Naches River Minor Tribs.	74,413	8,353	0
Yakima	Wenas Creek	11,109	3,010	0
Yakima	Rattlesnake Creek	75,430	0	48,972
Yakima	Upper Tieton River	122,347	6,551	52,937
Yakima	Lower Tieton River	55,290	9,964	6,296

b. Supply

The Forest annually contributes approximately 4.455 million acre-feet of high quality water to area streams, rivers, lakes, reservoirs, and ground-water aquifers. Runoff is orderly in most years with two annual peak flows--the highest in late May and a secondary peak in July. Maximum peak flood volumes historically occur in December, often associated with temperature inversions and rain-on-snow events.

Unregulated runoff during low flow periods is sustained by the gradual melting of the winter snow pack. Since a high percentage of the Forest's terrain averages greater than 3,500 feet in elevation, there is a significant contribution from melting snows throughout the summer.

Water benefits and utilization are enhanced through regulation facilities such as reservoirs operated by the Bureau of Reclamation. Summer streamflows are enhanced in several areas on the Forest through releases of stored water from six major reservoirs for irrigation and power production. Table III-36 lists these six reservoirs and their usable storage capacity. The mean annual storage for these impoundments over the 10 year period between 1967 and 1977 was 1,360,800 acre feet.

Water yield increases result from vegetation manipulation, such as timber harvest. However, these increases are only temporary unless the land use changes, as with a conversion of timber to pasture land. Yield increases due to timber harvesting are masked by the large magnitude and variability of natural water yield.

TABLE III-36

RESERVOIRS AND THEIR CAPACITY

Reservoirs	Sub-Basin	Usable Capacity (1000 Acre Feet)
Keechelus Lake	Yakima	157.8
Kachess Lake	Yakima	239.0
Lake Cle Elum	Yakima	436.9
Bumping Lake	Yakima	33.7
Rimrock Lake	Yakima	198.0
Lake Chelan	Chelan	676.1
	Total	1,741.5

Sampling of water quality to monitor background levels and effects of management activities began on the Forest in 1966. Monitoring of the Forest's 25 major watersheds between 1967-1980 involved nearly 20,000 samples. The water quality data in Table III-37 are the results of baseline and some project level monitoring between 1967 and 1980. The tabulation is a cross section of the water quality data collected throughout the Forest over this 13 year period. Several key parameters representing Class AA Washington State Water Quality Standards have been listed.

Mean values in the table suggest that the Forest has been complying with State Water Quality Standards; however, values describing the range indicate some measurements lying outside of these Standards. Refer to the Forest Water Quality Data Summary (in preparation) for details regarding the values and ranges displayed in this table. The Forest's water quality data base is located in STORET, a computerized data base system maintained by the U.S. Environmental Protection Agency (EPA).

The goal of project planning and implementation on the Forest has been to meet or exceed standards set forth in the State's Forest Practices Act.

Regional recertification of Forest Service management practices is needed in order to evaluate compliance of these practices with the recent major revisions of the Washington State Forest Practices Rules and Regulations.

The U.S. Environmental Protection Agency (EPA) and the U.S. Forest Service sampled twenty-seven lakes on the Wenatchee National Forest during the fall of 1985. Twenty-two of the lakes were within designated wilderness areas. The survey on the Wenatchee is part of the National Surface Water Survey, which is an effort to evaluate the extent of aquatic resources sensitive to acidic deposition. It will also assess the environmental effects on these resources. Results are being used to describe, by extrapolation, the overall status of lakes within each potentially sensitive region of the United States. This determination will establish a baseline from which future trends can be monitored on both a Regional and Forest perspective.

The Forest Watershed Improvement Program is designed to improve conditions in degraded areas. Refer to the discussion of this program under the soil resource section of this chapter for further details.

**TABLE III-37

c. Demand

Water has a primary importance for all types of uses, both on and off the Forest. The water on the Forest is essential for maintaining components of natural ecosystems, including vegetation, fish, and wildlife. High water quality is important for a healthy aquatic environment necessary for maintaining populations of resident and anadromous fish on the Forest. Many streams on the Forest are used by salmon and steelhead to complete their life cycle.

Many recreational activities such as fishing, boating, camping, and sight-seeing, are directly, or indirectly, water-based. Streams and lakes on the Forest are heavily used for sport fishing. The Cascades are famous for the aesthetic qualities of clean, clear, mountain streams and lake. Maintaining these qualities is what the public expects.

When it comes to irrigated agriculture, water is "king." Forest watersheds provide 95 percent of the water used for irrigation and domestic water systems in Chelan, Kittitas, and Yakima Counties. This region has a long growing season with productive soils upon which many potentially valuable crops are grown.

The downstream use of water flowing from the Forest has continued to increase dramatically over the past two decades. The Yakima Basin irrigators diverted 2.4 million acre-feet of water to produce a crop value of \$234,500,000 from 225,225 acres in 1981. (Source: 1981, Crop Production Reports--Yakima and Columbia Basin, Bureau of Reclamation).

Existing and foreseeable water shortages in the lower Yakima River are being identified through the on-going water rights adjudication in that sub-basin. It is improbable that potential irrigation water requirements on the Yakima Indian Nation Lands will be met with existing water storage facilities. Additional storage development would be required to produce an additional 200,000 acre-feet annually. Most of this development would occur on the Forest, affecting a wide range of other resources.

Forest watersheds provide domestic water for cities, small communities, organization sites, special use summer homes, and recreation areas. Municipal watersheds on the Forest are managed for the

complete range of multiple use activities. Water flowing from these drainages must be suitable for domestic use with cost effective treatment procedures. The public expects clean water from the Forest and management activities are directed toward supplying these needs.

In most cases, the application of multiple-use management will provide the needed protection of water quality in municipal watersheds without the use of agreements. The Forest has been negotiating with the City of Roslyn to reach a mutual land management philosophy on the Domerie Creek Watershed. Currently, neither a formal nor an informal agreement has been executed by either party. An executive order was issued by President Harding in 1923 to protect those lands lying within the Rattlesnake and Little Rattlesnake Watersheds for the water supply of the City of Yakima.

Instream flows within the National Forest boundary have not been a critical issue. The Forest currently has sufficient stream discharge flowing from unregulated water sources so that requirements for instream or minimum flows on the Forest are not anticipated in the short term.

There has been some concern regarding the potential impact of proposed small hydroelectric projects. These may reduce streamflows to a volume that could adversely affect channel maintenance processes and aquatic habitat. The Forest monitors this potential situation through the environmental analysis process for specific proposals in cooperation with other State and Federal agencies. This coordination also exists when support is needed to assure adequate flows to support anadromous fish passage.

Prior to the mid-1970's, the Forest Service enjoyed reserved water rights for all Forest-oriented water uses under the long standing Reservation Principle. A Supreme Court decision changed this unencumbered right, restricting reserved water privileges to those uses necessary for timber management activities and watershed protection.

Current Forest resource management activities require water use at nearly 825 designated points of use. All non-Reserved Forest water uses have Certificates of Water Rights or have applications pending with Washington State's Department of Ecology.

d. Cumulative Effects

Cumulative effects are the impacts resulting from a series of management activities occurring within a defined watershed over a span of time. These "activities" could be nearly any kind of project on any land, regardless of ownership. The current primary issue regarding cumulative effects on water is the potential impact of timber harvest and road construction occurring in drainages of mixed ownership. There can also be cumulative effects in drainages of solid National Forest System lands, as well as effects felt downstream of the Forest boundary.

In "checkerboard" ownership areas within the Forest boundary, the private landowners are generally large, industrial forest companies. State ownership is the Washington Department of Wildlife and the Department of Natural Resources. The principal owners of private lands are Burlington Northern Railroad (Plum Creek Timber Company), Longview Fibre Company and Boise Cascade Corporation. These landowners manage their lands primarily for the production of timber. Their management goals can dictate a much faster rate of harvest of the existing mature timber than is occurring on the adjacent National Forest lands.

TABLE III-38

CUMULATIVE EFFECTS ON WATER WITHIN DIFFERENT SUB-BASINS OF THE WENATCHEE NATIONAL FOREST

EFFECTS OF MANAGEMENT ACTIVITIES ON THE FOLLOWING	SUB-BASINS

At present the management objective of the two largest landowners within the Forest (Plum Creek and Longview Fibre) is to harvest their old growth timber in the next 10 years. Harvest of these "checkerboard" lands is currently in progress with current or potential cumulative effects on certain watersheds already identified. Neither the Forest nor any state agency has jurisdiction over the rate of harvest of these private lands within any given watershed as long as State standards are being met.

Table III-38 briefly addresses the cumulative effects topic within the four major sub-basins on the Forest. The matrix shows whether there has been, is, or may be in the future a cumulative effect due to more harvest activity. Where "none known" is written in the matrix it is considered that no known cumulative effects exist. Where any other statement is listed, a brief discussion of the situation is provided in a numbered section in the following narrative. Refer to the cumulative effects sections for the soil and fish habitat resources in this chapter for additional information.

Description of Effects Indicated in Matrix

1. Mining operations occurred within the Railroad Creek drainage between 1938 and 1957. During this 20-year period, piles containing millions of cubic yards of mine tailings were deposited on National Forest lands. The mine tailings cover approximately 80 acres adjacent to Railroad and Copper Creeks.

Water quality monitoring in Railroad Creek was ongoing from the early 1970's through 1981. The tailings contain some very toxic levels of arsenic, copper, lead, zinc, and cyanide. In addition, the possibility exists that a major flood event could cause the scouring and undercutting of the tailings and subsequent bank slough and erosion of these materials directly into Railroad Creek. A major rehabilitation effort is currently underway at this site.

2a. In the early 1970's, hot wildfires burned large portions of the Entiat watershed. Riparian vegetation has been slow to reestablish on certain tributaries. Water temperatures during low flow conditions on these tributaries have been affected. No formal water quality sampling has been done since 1977. No significant temperature problem is currently known to exist in the Entiat River itself because of the small volume of flow contributed by tributaries affected by the fires.

2b. The Entiat River basin is suspected of having had its flow regime changed because of the large wildfires in the early 1970's. Watershed condition in the affected tributaries has improved since this disturbance, and no significant problem with runoff timing is thought to exist at this time.

3a. The Wenatchee River basin may have a problem with accelerated sediment delivery because of the impacts of timber harvest and road construction in intermingled ownerships. This is primarily a concern in specific sub-drainages of the Wenatchee River. For example, Mission Creek has long been a management concern due to its high percentage of sensitive soils and sediment contributions to the mainstem.

3b. Timing of runoff may be affected by timber removal. The possible runoff effect was identified because of the past and future logging in the Upper Yakima River basin on Plum Creek Timber land, and in the Wenatchee River basin on Longview Fibre's Company land in conjunction with logging activities on the Forest.

4a. Cabin, Log, and Meadow Creeks, in the upper part of the Yakima drainage, have been heavily logged down to the stream channels. Major flood events triggered by rain-on-snow have also contributed to the removal of riparian vegetation. As a result, streamside shade has been significantly reduced along major sections of these stream channels. Warm water temperature during low flow periods could be a problem; however, no current water temperature data exists for these tributaries.

4b. An accelerated sedimentation problem currently exists in Cabin, Log, and Meadow Creeks in the upper part of the Yakima drainage. These channels are still in a condition that promotes sediment delivery.

There are a lot of intermingled private lands in the northern half of the Little Naches drainage. Both Plum Creek Timber Company and the Forest Service are currently logging in this area. The potential for a cumulative effect on sediment yield exists due to the erodibility of some of the soil types in the area, the stability of some of the landforms in the area, and the rate of harvest on private lands in conjunction with activities on National Forest System lands.

4c. Based on the level of activity on lands of all ownerships in this drainage, the potential exists for downstream damage from a major flood event.

4d. No problem currently exists but many mining claims are active on a small scale in the Yakima Basin. If a major strike was made, or if the many small claims were consolidated, a toxic by-product of gold processing (such as from cyanide treatment) could cause concern in the future.

Mercury claims also exist in the Wildcat watershed of the Tieton Basin. Toxic by-products of recovery could possibly be a problem in the future if large scale mining and mercury extraction processes were used.

11. SOILS

a. Overview

The National Forest Management Act of 1976 (NFMA) requires the Forest Service to maintain or enhance soil productivity. Soil is a basic environmental component. It is essentially a non-renewable resource, because soil formation occurs very slowly over long periods of time. Soil loss or damage (e.g., erosion, compaction) can have a significant effect on soil productivity, thus minimizing these kinds of impacts is essential.

One of the more important roles of forest soils is their ability to absorb and store water, then release it slowly over time. The slow release of stored soil water is especially important for late summer stream flows, which can affect fish habitat, as well as the availability of water for irrigation and other uses.

The Wenatchee National Forest is a large forest and has within its boundary more than 200 different kinds of soils (see: "Soil Resource," Snoqualmie National Forest (Eastside), published in April 1973; and "Soil Resource Inventory" (SRI), Wenatchee National Forest, published in 1976). Soil formation is dependent on five factors: parent material; topography; climate; organisms; and time. The reason that the Forest has so many different kinds of soils is because it has a wide range of parent materials (more than 30 different geologic formations), wide ranges in elevations (800 to 9,500+ feet), wide ranges in precipitation (9-120+ inches), dramatic topographic variations, several different sets of transported (ice, water, wind) soils, and finally a range in time during which soil formation has been taking place.

The Soil Resource Inventories (SRI's) are reconnaissance type surveys, intended for broad planning purposes (e.g. The Forest Plan). They have been used in planning to identify unstable soil areas, as well as some soils that could have regeneration problems. Soil information was also used to some degree in the development of the management prescriptions for the Forest Plan.

Reconnaissance type surveys are not detailed enough for project level work. Therefore, the Forest entered into a cooperative soil survey agreement with the Soil Conservation Service (SCS) in 1980 to make a more intensive soil survey on the National Forest lands in Kittitas and Chelan Counties. The soil survey in Kittitas County was completed in the fall of 1981, with Chelan County completed in the spring of 1989. A similar arrangement was made with the SCS to update the soil survey in Yakima County (Naches Ranger District) with the field work starting in June of 1989.

A degraded acre inventory was conducted on the Forest from 1978 through 1980. The purpose of the inventory was to identify areas that have significant soil or water problems, and are eroding or causing other management problems. During the 3 year inventory period, 143 degraded sites were identified. The inventory data sheets were reviewed again by the ranger districts in the spring of 1989 to see if these sites were still a problem, to remove those that had been rehabilitated, and to

make up a data sheet for any sites that should be added to the list. After completing this, the districts were asked to prioritize their lists. Finally, a priority list for the Forest was developed for the most important sites.

b. Cumulative Effects

Soil productivity and mass wasting are the principal areas of concern on the Wenatchee National Forest, because they can both be affected by management activities. Timber harvest, road construction, road reconstruction, and residue treatment have the most potential to impact the soil resource.

Soil erosion is the origin of most of the delivered sediment. And it is the delivered sediment that can have a negative effect on water quality and fish habitat. Overland flow, either from spring runoff or from a high intensity storm, is the cause of most of the sediment. Without overland flow, there is very little erosion. Wind erosion may occur on some of the ash soils, if the surface soil is exposed and left unprotected.

Soil compaction can significantly reduce soil productivity, therefore, it is important to prevent unnecessary compaction. Compaction often occurs as a result of management activities (timber harvest, machine slash piling, campgrounds, trails, etc.), thus it is important to stay within acceptable standards in order to minimize the overall effect.

Some soil materials are more easily compacted than others, and most soil materials are more easily compacted when moist than when dry. Compaction in forestry operations most often occurs as a result of the use of ground skidding equipment, or equipment (tractors) used to pile the residue after timber harvest. Each trip across a particular location with a piece of machinery or log will cause some compaction. With each succeeding trip, compaction effects become cumulative. Soil compaction in some places on this Forest is known to have lasted more than 17 years.

Not all soil compaction is bad, in fact soil compaction is desirable in road construction. However, because it reduces soil productivity in terms of the amount of timber and forage the land can produce, it is not desirable for the Forest in general.

Nutrient losses are of concern because if nutrient levels are allowed to decline very far, then the productivity of the site is reduced. These losses most often occur in two ways: first, by erosion losses of the surface horizon; and second, by volatilization by fire. Nutrient losses occur slowly over time, so the effects are hard to measure, but the cumulative effect is considered to be negative.

Mass wasting includes slump-earth flows, debris avalanches, and debris torrents. They can either be triggered by natural events or by management related activities. They become significant when they are 50 cubic yards or larger, and directly impact a live stream or lake, or when they are 200 cubic yards or larger and present a threat to capital investments (e.g., roads). All failures can be a threat to human life.

There are four major river basins on this Forest--the Chelan, Entiat, Wenatchee, and Yakima. Analysis of these river basins is one way to group soils in order to evaluate the cumulative effects of applied prescriptions.

Cumulative Effects Matrix

The units of measure for comparing cumulative effects are: YES, POSSIBLE, and NONE KNOWN. YES, means that the activity (whatever it is) has a significant impact and there are negative cumulative effects. POSSIBLE ("poss" in the table) means that the activity may have a significant impact but possible negative effects can be avoided. NONE KNOWN ("none kn" in the table) means that the activity will not have a significant impact and it will probably not have a significant cumulative effect. Some of the ratings were made on the basis of professional judgment and experience, and others were made on the basis of monitoring and/or research information.

There are three location categories for classifying cumulative effects. They are: 1) NATIONAL FOREST; 2) WITH/INTERMINGLED OWNERS; and 3) OFF-FOREST (down stream). These three groupings were used because the location of the particular effect can have a bearing on future management decisions.

Description of Effects Indicated in the Matrix

1. In the Chelan River basin, the Holden tailings present a major hazard for erosion or mass failure, because the protective cribbing at the base of the piles is very old and is now in a deteriorated condition.

The Chelan River basin is subject to periodic high intensity storms (convective storm events). Most of the soils have developed in volcanic ash and pumice. These soils are non-cohesive and tend to be easily displaced when the protective surface vegetation has been removed. Slumps and debris torrents are also an ever present risk.

2. Many of the soils in the Chelan, Entiat, and Wenatchee River basins are subject to soil compaction. Most soils that occur on slopes flatter than 40 percent will probably be managed with some type of ground skidding equipment. The cumulative effects of compaction generally show up over time after repeated entries into a particular timber stand. Compaction does not discriminate; it can occur on privately owned lands just as easily as it does on National Forest lands.

TABLE III-39

MATRIX OF CUMULATIVE EFFECTS ON THE SOIL

SOIL PRODUCTIVITY	<u>RIVER BASINS</u>			
	CHELAN	ENTIAT	WENATCHEE	YAKIMA
Soil Erosion				
National Forest	poss (1)	poss (5)	poss (7)	poss (9)
W/Intermingled Owners	none kn	none kn	poss (7)	poss (9)
Off-Forest (downstream)	none kn	poss (5)	poss (7)	poss (9)
Soil Compaction				
National Forest	poss (2)	poss (2)	poss (2)	poss (10)
W/Intermingled Owners	none kn	none kn	poss (2)	poss (10)
Off-Forest (downstream)	none kn	none kn	none kn	none kn
Nutrient loss				
National Forest	poss (3)	poss (3)	poss (3)	poss (3)
W/Intermingled Owners	none kn	none kn	poss (3)	poss (3)
Off-Forest (downstream)	none kn	none kn	none kn	none kn
Mass Wasting				
National Forest	poss (4)	poss (6)	poss (8)	poss (11)
W/Intermingled Owners	poss (4)	poss (6)	poss (8)	poss (11)
Off-Forest (downstream)	poss (4)	poss (6)	poss (8)	poss (11)

Soil compaction reduces water infiltration rates, thereby increasing the probability of overland flow and soil erosion. Also, it can have a negative effect on root development, because it affects soil porosity (makes the soil more dense), soil permeability, and the water holding capacity of a soil. The end result is that soil compaction can reduce soil productivity. Breaking down the compacted layers in any soil occurs very slowly, so will take a long time for this to happen if the process takes place naturally. There are some management practices available (e.g., tillage, special plant mixes, etc.) that can speed up the breakdown of the compacted layers; however, some of them are expensive and their effectiveness may be limited by local site conditions. There are no effects off-Forest, other than perhaps increased runoff.

3. Nutrient losses in the Chelan, Entiat, Yakima, and Wenatchee River basins can occur via soil erosion, because many of the soils have a thin "A" horizon, which generally contains most of the available nutrients. Nutrient losses often occur as a result of fire, either wildfire or prescribed burning, since most of the nutrients in forest residues are located in the needles, twigs, and small branches. These fine materials are the ones that are usually totally consumed by fire. Hot fires also tend to volatilize some nutrients, so that they are lost to the atmosphere. Furthermore, hot fires can create a hydrophobic condition (non-wettability quality) in the surface of some soils. When this condition exists, the affected soils become very erosive, particularly during high intensity storm events. Nutrient cycling and organic matter maintenance is also very important and is becoming a major consideration in project design and contract administration. Nutrient losses can be cumulative over time, so the soils need to be monitored.

The management strategies used by private owners on the intermingled lands can also have an effect upon the overall nutrient levels in any given sub-drainage. In some places, the private land owners do not burn the logging slash.

4. Mass wasting (slumps, slides, and debris torrents) in the Chelan River Basin has occurred in the past. Most of these events have been debris torrents, some of which have had very dramatic local effects. All of these events have occurred after a watershed has been denuded by wildfire.

5. The Entiat River basin is subject to periodic high intensity storms (convective storm events). Many of the soils formed in volcanic ash and pumice are very erosive once the surface vegetation has been removed. They also seem to be subject to a lot of debris torrents. Most of these events have occurred after a watershed has been denuded by wildfire with some of these events having had some very dramatic downstream effects. The Preston Creek event killed four people and demolished several cabins at the mouth of the canyon. The Crum Canyon floods (two separate events) caused over one million dollars in property damage to both public and private property, including the interruption of both highway and rail travel, as well as blockage of the Entiat River for a short time. The effects of these kinds of events can be very expensive, as well as long lasting. Slumps in this drainage are less common, but they can have some very significant effects, such as closing roads, etc.. Examples are: Kloochman Gulch and Tillicum Creek that have had some major slumps and earth flows in the past. Debris torrents in other cases have caused serious damage off-Forest.

The effects of erosion has shown up off-Forest by the abrasive nature of the volcanic ash that has caused excessive wear to irrigation pumps and sprinkler heads.

There are so few intermingled owners that the cumulative effects are insignificant.

6. Kloochman Gulch and Tillicum Creek, in the Entiat River Basin, have had some major slumps and earth flows in the past. The ones in Tillicum Creek have on several occasions blocked Forest roads, and have contributed large amounts of sediment into Tillicum Creek. The entire river basin is subject to high intensity storms and debris torrents which in some cases have caused a great deal of damage off Forest. Examples of this are the Preston Creek and Crum Canyon floods. The effects of these kinds of events can be very expensive, and can also have a long-term effect. Most of the debris torrents have occurred after a large wildfire has denuded a watershed.

7. In the Wenatchee River basin, the most erosive soils are those that have formed in Chumstick sandstone materials. These soils are the major source of delivered sediment into the Wenatchee

River. Mission Creek is possibly the most sensitive, and has the potential of having the greatest off-Forest effect, because the city of Cashmere is located at the mouth of the Mission Creek drainage.

The Wenatchee River basin has a large number of privately owned sections of land that are intermingled with National Forest sections ("checkerboard" pattern). The effect of management activities that occur on the privately owned lands when added to the effects of management activities taking place on the National Forest lands can result in a cumulative effect for each sub-drainage affected.

8. In the past, mass failures have occurred in the Little Wenatchee River drainage, along Pole Ridge, and in Coulter Creek. There are landforms in other parts of this river basin that show evidence of old slumps but are now stable. High intensity storms and rain on snow events are not uncommon to this area, and either kind of event can trigger a debris torrent, or a slump or a slide. The risk of a high intensity storm occurrence is greater in the eastern part, whereas, a rain on snow event is more likely to occur in the western part of this basin.

9. The Yakima River basin is very large because it includes several smaller river basins (Cle Elum, Teanaway, Naches, American, Little Naches, and Tieton). There are many different kinds of soils in it, and many of them are fine textured (i.e. contain a high content of silt and clay). A common characteristic of clay type soils is that once the silts and clays have become suspended in water (erosion), they tend to stay in suspension and can travel for long distances. Because of this, the suspended sediments can affect many off-Forest facilities, such as the filtration system for the City of Yakima.

The upper part of the Yakima River basin contains a lot of intermingled private lands ("checkerboard"), so the effects of management activities on the private lands when added to the management activities on the National Forest lands can have a cumulative effect on the total amount of delivered sediment from any given watershed (the Cabin and Log Creek drainages are examples of this).

10. Many of the soils in the Yakima River basin are subject to soil compaction. Most soils that occur on slopes flatter than 40 percent will probably be managed with some type of ground skidding equipment. Soils that have formed in Chumstick sandstone, basalt, or pyroclastic materials are all easily compacted. The cumulative effects of compaction generally show up over time after repeated entries into a particular timber stand. Restoration occurs very slowly over time, if allowed to take place naturally. Compaction can also occur on privately owned lands and the effects are much the same as those found on National Forest lands. Soil compaction reduces water infiltration rate, thereby increasing the probability of overland flow and erosion. It also makes the soil more dense so that root development is affected. Furthermore, it usually reduces soil porosity, soil permeability, and the water holding capacity of the soil. Because of these factors, soil compaction often reduces soil productivity. There are no effects off-Forest.

11. Mass failures are common in some parts of the Yakima River basin. Areas that have large amounts of pyroclastic materials generally have the greatest number of slumps and slides. These particular pyroclastic materials generally weather into clays that have high shrink/swell characteristics (montmorillonitic clays). Many of the soils in the southern part of this basin have significant amounts of clay in the subsoil. When the clays erode, they become suspended in the water, and will generally stay in suspension and travel for great distances. This can affect domestic water supplies, irrigation systems, and fish habitat in some cases.

Debris torrents can and do occur in this river basin but most often they will occur on southwest, south, and southeast aspects. Rain-on-snow events are fairly common along the western part of the river basin in the higher precipitation zones near the crest of the Cascades. Off-Forest interests can be affected by either debris torrents or rain on snow events. The intermingled private lands are also subject to the same hazards and risks as are the National Forest lands.

12. AIR

Air is both an essential component of all forest ecosystems and an aesthetic resource. The impacts of our culture's activities on this resource have not been well measured or documented on the Wenatchee National Forest. Historical data describing the air quality is very sparse and primarily limited to visibility. Documentation exists of impairment to visibility resulting from the smoke generated by either wildfires or prescribed fires. However, data concerning the chemical composition of the atmosphere over the Wenatchee National Forest is essentially non-existent.

By comparison to the more densely populated areas that surround the Forest, the air quality within the Forest boundary could normally be described as "good". Measureable quantities of those substances commonly considered pollutants such as sulfur dioxide, ozone, and the oxides of nitrogen have not been found above National Forest lands. Pollution levels measured in the Puget Sound area west of the Mt. Baker-Snoqualmie National Forest are, with the exception of ozone, normally well within the state and federal ambient air quality standards. The concentration of ozone at times, does exceed the established standards. The areas of highest known ozone concentration remain well to the west of both the Mt. Baker-Snoqualmie and Wenatchee National Forests. Detrimental impacts on the forest resources from ozone concentrations have not been documented.

Suspended particulates are of concern due primarily to their impact on visibility. Forest management activities which create smoke or generate dust are the primary contributors to the degradation of visibility. Prescribed fire is the land management activity on the Forest which generates the largest quantity of suspended particulates with a resultant decrease in visibility.

In an attempt to reduce the impacts on air quality created by prescribed fire, several actions have been initiated. Increased utilization of wood fiber for a variety of products has reduced the amount of material considered debris and subject to disposal by prescribed fire. At the same time, the use of predictive models to replicate both atmospheric and fuelbed conditions have allowed land managers to decrease the consumption of fuels not in need of disposal and to ensure rapid dispersion of the resultant smoke. The Washington State Implementation Plan is a document outlining the objectives and procedures utilized in the State of Washington to comply with the Clean Air Act of 1974. Compliance with the Washington State Implementation Plan is mandatory whenever prescribed fire is utilized as a land management tool.

The Forest also administers three federally designated Class I airsheds in conjunction with the Glacier Peak, Alpine Lakes, and Goat Rocks Wilderness Areas. The Clean Air Act mandates that federal land managers protect the air quality related values in these areas. This protection includes ensuring that smoke intrusions from prescribed fires do not occur and, in conjunction with the Washington State Department of Ecology, reviewing all applications which propose major pollutant emitting facilities with the potential to adversely impact a Class I area.

The airshed associated with the Alpine Lakes Wilderness has been selected to be the first Wilderness in the Pacific Northwest Region for which a formal Air Resource Monitoring Plan will be developed. The first quantitative data regarding the chemical composition of the airshed should be collected in 1989, with a goal of establishing baseline values early in the next decade.

The quality of the air resource on the Wenatchee National Forest can be described as "good" in comparison to the more populated areas which surround the Forest. The managers of the Forest recognize their responsibility to manage this resource and are moving ahead toward implementing procedures to improve the quality of the data available and to establish baseline values for quantifying the quality of our air resource.

13. MINERALS

a. Overview

The Forest Service recognizes that minerals are fundamental to the Nation's well being, and, as policy, it encourages and facilitates the exploration for and development of the mineral resources it manages. Its objective is to manage for exploration, development, and production activities in a timely manner, while insuring those activities are integrated with the use, conservation, and protection of all other resources. In summary, the minerals program policy of the Forest Service, including the Wenatchee National Forest, is as follows:

1. Encourage and facilitate the orderly exploration, development, and production of mineral and energy resources within the National Forest System in order to maintain a viable, healthy minerals industry and to promote self-sufficiency in those mineral and energy resources necessary for economic growth and the national defense.

2. Ensure that exploration, development, and production of mineral and energy resources are conducted in an environmentally sound manner and that these activities are integrated with the planning and management of other National Forest resources.

3. Ensure that lands disturbed by mineral and energy activities are reclaimed for other productive uses.

Mineral commodities are classified by law into three distinct groups; locatables, leasables, and salables. The manner in which each is managed and the authority of the Forest Service to control the exploration for and development of each commodity varies considerably.

Locatable minerals are those minerals which, when found in valuable deposits, can be acquired under the General Mining Laws of 1872, as amended. Examples of locatable minerals occurring on the Wenatchee National Forest include, but are not limited to, copper, gold, molybdenum, iron, chromite, nickel, zinc, silver, lead, and uncommon varieties of limestone, gemstones, and other minerals having unique and special values.

**TABLE III-40
MINERAL DISPOSAL AND ACTIVITY RESPONSIBILITIES**

Commodity	Public Domain - Administered by the FS	Acquired Lands - Administered by the FS	Preliminary Prospecting Permits
Oil and Gas	BLM requests FS consent for leasing	BLM requests FS consent to lease and FS concur-	FS has authority to issue a permit
Coal	BLM requests FS consent to lease and permit to operate	BLM requests FS consent to lease and permit to operate	FS permit specifically prohibited
Hardrock Minerals	Locatable--Nondiscretionary	BLM requests FS consent to issue a prospecting permit, to lease and to operate	FS has authority to issue a permit
Geothermal	BLM requests FS consent to lease and to operate	BLM requests FS consent to lease and to operate	FS has authority to issue a permit

BLM - Bureau of Land Management
FS - Forest Service

Citizens and those who have declared their intent to become citizens of the U.S., have a statutory right to explore vacant unwithdrawn public land for these minerals. Upon discovering a valuable deposit, they have a right to locate, mine, and remove the minerals. Forest Service control of these activities is limited to minimizing impacts on surface resources. This is accomplished by reviewing plans of operation to ensure environmental protection standards are established and met. This includes, in addition to many others, standards for air, water, cultural resources, and threatened and endangered species. Assuring prompt reclamation or restoration of disturbed lands is accomplished as part of the operating plan process.

Designated wilderness areas, wild segments classified under the Wild and Scenic Rivers Act, and other withdrawn areas are not open to mining claim location. However, these areas are subject to any valid existing rights perfected prior to the date the area was withdrawn. Acquired lands are not subject to the location of mining claims under the 1872 Mining Law, but are subject to mineral leasing under the Acquired Lands Leasing Act.

Leasable minerals are those mineral commodities which may be acquired under the Mineral Leasing Act of 1920, as amended. On the Wenatchee National Forest, they include coal, oil, gas, and geothermal resources, as well as all minerals except salables when occurring on acquired lands. These minerals are subject to exploration and development under leases, permits, or licenses which are issued by the Secretary of Interior upon receiving consent to lease from the Forest Service. Since leasing is a discretionary action requiring Forest Service consent, its control of prospecting and development activities is considerably stronger than it is for locatable minerals. Although the Forest Service has more control on their activities, its management objective is still to encourage and facilitate leasable mineral activities. Table III-40 summarizes Forest Service mineral leasing responsibilities for the public land it administers.

Recommendations concerning the availability of lands for mineral leasing are based on whether development activities could be conducted in a manner which is compatible with land management objectives in the Forest's land management plan.

The policy and procedures by which mineral use authorizations for federally owned leasable minerals are to be processed are being established in compliance with the Federal Onshore Oil and Gas Leasing Reform Act of 1987. It is presently assumed that an assessment of oil and gas resource potential will be made and a National Environmental Policy Act (NEPA) evaluation will be completed. Based upon that evaluation, lands will be selected for leasing by a competitive or over-the-counter system. Once leases are issued, on-the-ground activities will be managed in keeping with the Interagency Agreement between the Forest Service and the Bureau of Land Management (BLM) dated June 19, 1984. In summary, the agreement calls for the Forest Service to participate with the BLM in the formulation of site-specific terms and conditions in the operating plans. The plans must provide appropriate mitigation measures to insure that adverse impacts on surface resources will not exceed applicable environmental protection standards.

Salable minerals are common varieties of sand, stone, gravel, pumice, pumicite, cinders, and clay. In general, these minerals are of widespread occurrence, of relatively low unit value, and are generally used for construction materials or for road building purposes. These minerals are disposed of under the authority of the Materials Act of July 31, 1947, as amended by the Act of July 23, 1955. Disposal of salable minerals from public lands administered by the Forest Service is totally at the discretion of the Forest Service (see regulations in 36 CFR part 228). Management of operations on permit areas is similar to the management of leasable mineral activities.

b. Geologic Setting

The Wenatchee National Forest lays along the east side of the crest of the Cascade Mountains. This mountain range consists of a core of crystalline metamorphic rocks intruded by dominantly granitic to dioritic stocks and batholiths. Relatively recent volcanic activity resulted in extensive andesitic flows in the southwest part of the Forest. Tertiary coal-bearing sandstones and shales are distributed throughout the east-central and southeast parts of the Forest. Metallic mineral deposits are generally related to the

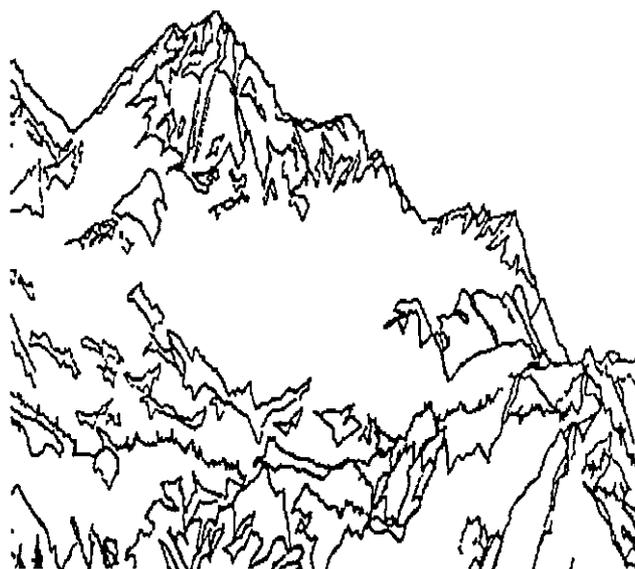

igneous/metamorphic complex, however, gold is also found in silicified zones within Tertiary sandstones in the east-central part of the Forest. The geothermal potential is controlled by the location of recent volcanic activity. The coal, oil, and gas potential is limited to folded sediments in the flanks of the Columbia River basin. Common variety minerals occur throughout the Forest, whereas mineral collecting for recreation purposes is generally limited to about nine areas.

c. Recreational Minerals

Although there are about twenty types of minerals recreationally collected on the Forest, placer gold, agate, quartz crystals, garnet, talc or soapstone, olivine, rhyolite, pyrite, rhodenite, and actinolite appear to be the main targets of collectors. The areas experiencing the most activity of this nature are located on the Cle Elum and Leavenworth Ranger Districts. The type of activity involved in collecting generally includes pick and shovel work, but panning, sluicing, and suction dredging have also become increasingly popular.

Those collectable minerals of a "locatable" nature are removed from valid mining claims under the authority of the Mining Law of 1872 as amended, whereas removal of more than nominal amounts of the common variety minerals requires that a permit be issued. In either case, if significant surface resource disturbance might be caused, a notice of intent or plan of operation must be filed and approved. If suction dredging or stream alteration is involved, a hydraulic project approval must also be obtained from the State. Since managing this type of activity in the past has not been a significant problem and it is not anticipated to become a problem in the future, current management practices will continue.

There does appear to be some interest in the opportunity to allocate lands specifically for rockhounding and mineral collecting purposes. Other than for those areas identified in the Alpine Lakes Management Plan (Redtop Mountain area and portions of Peshastin, Negro, and Ruby Creeks), no areas will be withdrawn and specifically managed for this type of recreational activity. However, recreational panning, sluicing, dredging, and collecting will be encouraged and facilitated whenever these activities can be conducted in a manner compatible with the land management objectives and legal status of the land.

d. Locatable Minerals

A mineral resource overview has been prepared to assess the present and future potential for the development of locatable mineral resources on the Wenatchee National Forest. It indicates, on a relative scale, the odds for successfully finding mineral resources which can be profitably developed. Table III-41, along with Figure III-10, depict the areas on the Forest which appear to have potential for the occurrence of mineral resources.

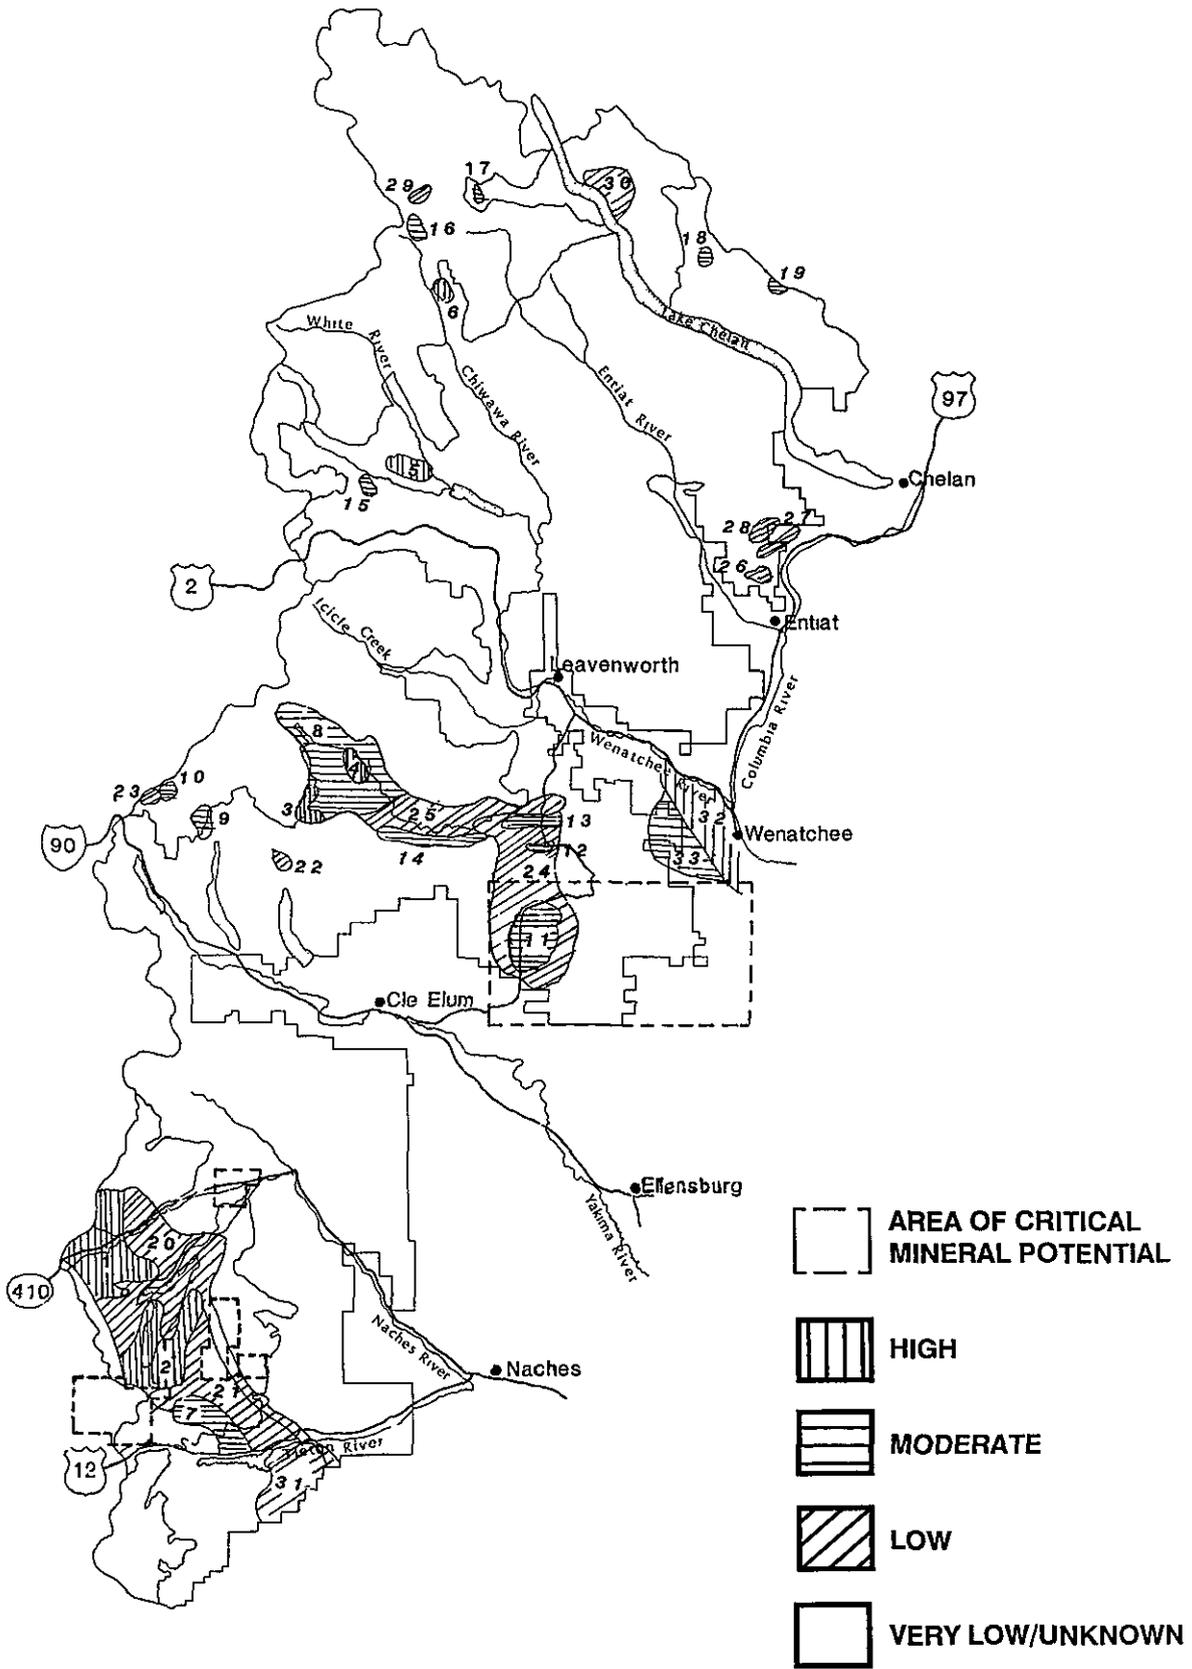

As Table III-41 indicates, the Forest contains a potential for significant occurrences of copper*, gold, molybdenum, silver*, lead*, zinc*, tungsten*, iron*, chromium*, nickel*, mercury*, and manganese*, in approximate decreasing order of importance. (*Commodities are identified as critical or strategic minerals.) The Forest also contains potentially commercial deposits of bentonite, feldspar, limestone, and garnet. The other nonmetallic minerals reported either have no apparent commercial potential or are of interest only to collectors.

The Wenatchee National Forest has a long history of mining dating back to 1860, and numerous claims have been located and maintained since the 1870's. Available information indicated that, excluding the Holden Mine, the Forest has had a modest past production record. That record is fragmentary but it is the best data available and is summarized in Table III-43.

Exploration has been carried out intermittently throughout the Forest since the late 1800's. Recently, following the Cannon mine discovery made near Wenatchee in 1983, more than 7,000 mining claims were located in the Liberty or Swauk Creek area, in the Culver Gulch area, and in a 10 to 12 mile wide belt lying west of Wenatchee. As an additional response of that discovery, mining activity in the State during 1984 was dominated by the activities in Chelan, Douglas, and Kittitas Counties, and that activity has continued through 1989.

Although the Forest has approximately 11,000 mining claims covering 200,000 acres properly recorded as being located within it, present mineral activity on Forest Service lands is relatively minor in scope. As a consequence, it is assumed that mineral resources on the Forest presently play a limited role in National, Regional, and State-wide social and economic structures. However, the economic and, to some extent, the social characteristics of southern Chelan County and northern Kittitas County may be significantly impacted over the next ten years by the new mining industry centered in Wenatchee. As depositional models are extrapolated to other areas and new exploration targets are identified, Forest Service lands may also be affected by this activity. Confidence in this projection decreases toward the end of the planning period because future activities will actually depend upon the technical results of the exploration and development conducted during 1984-85. It also depends on the volatile nature of the minerals market.

Fortune Creek	Camp Creek	Unknown	Unknown	Au, Ag
1/	Au-Gold Ag-Silver Cr-Chromium Cu-Copper	Fe-Iron Hg-Mercury Mo-Molybdenum Mn-Manganese	Ni-Nickel Pb-Lead Wo-Tungsten Zn-Zinc	

The areas most likely to be explored for gold within the next few years include the Horse Lake Mountain and Blewett areas on the Leavenworth Ranger District and the Swauk Creek area on the Cle Elum Ranger District. The Horse Lake Mountain activity probably will expand northerly along the Entiat Ridge approaching the Lake Wenatchee Ranger District. The Swauk Creek activity will expand westerly and northwesterly across Red Top Mountain and along the south flank of the Mt. Stuart batholith, possibly as far west as the Cle Elum River.

Silver-based metal mineral resources with one exception, appear to be of low grade and of small volume relative to grade. These probably will require supply constraints and significant price increases in order for development to take place. Targets of this type include Trinity, where current exploration and development is expected to continue, and Van Epps Pass, where renewed interest and claim staking began in 1984. The exception is the Chelan-Sawtooth area where evidence is emerging of medium to high-grade silver deposits with associated lead and zinc.

Precious metal exploration and development has dominated the mineral activity over the past couple of years. However, base metal deposits (copper, lead, zinc, tungsten, iron, and chromium) will remain targets of future exploration activities. The extent and grade of the nickel-chromium-iron deposits in the Cle Elum Nickel-Iron, Blewett-Iron, and Teanaway areas are well established. However, the cost of mining, international market competition, market conditions, and difficult extractive metallurgy make the future development of these commodities unlikely in the absence of a national emergency.

Nonmetallic mineral resources of a possibly locatable nature include feldspar, garnet, and bentonite deposits. Of these, the Wenatchee Ridge feldspar deposits appear to have the most potential for future development. Actual development of any of the three commodities will depend more upon processing technology, commodity research, and the establishment of markets, than on exploration and development activities.

e. Leasable Minerals

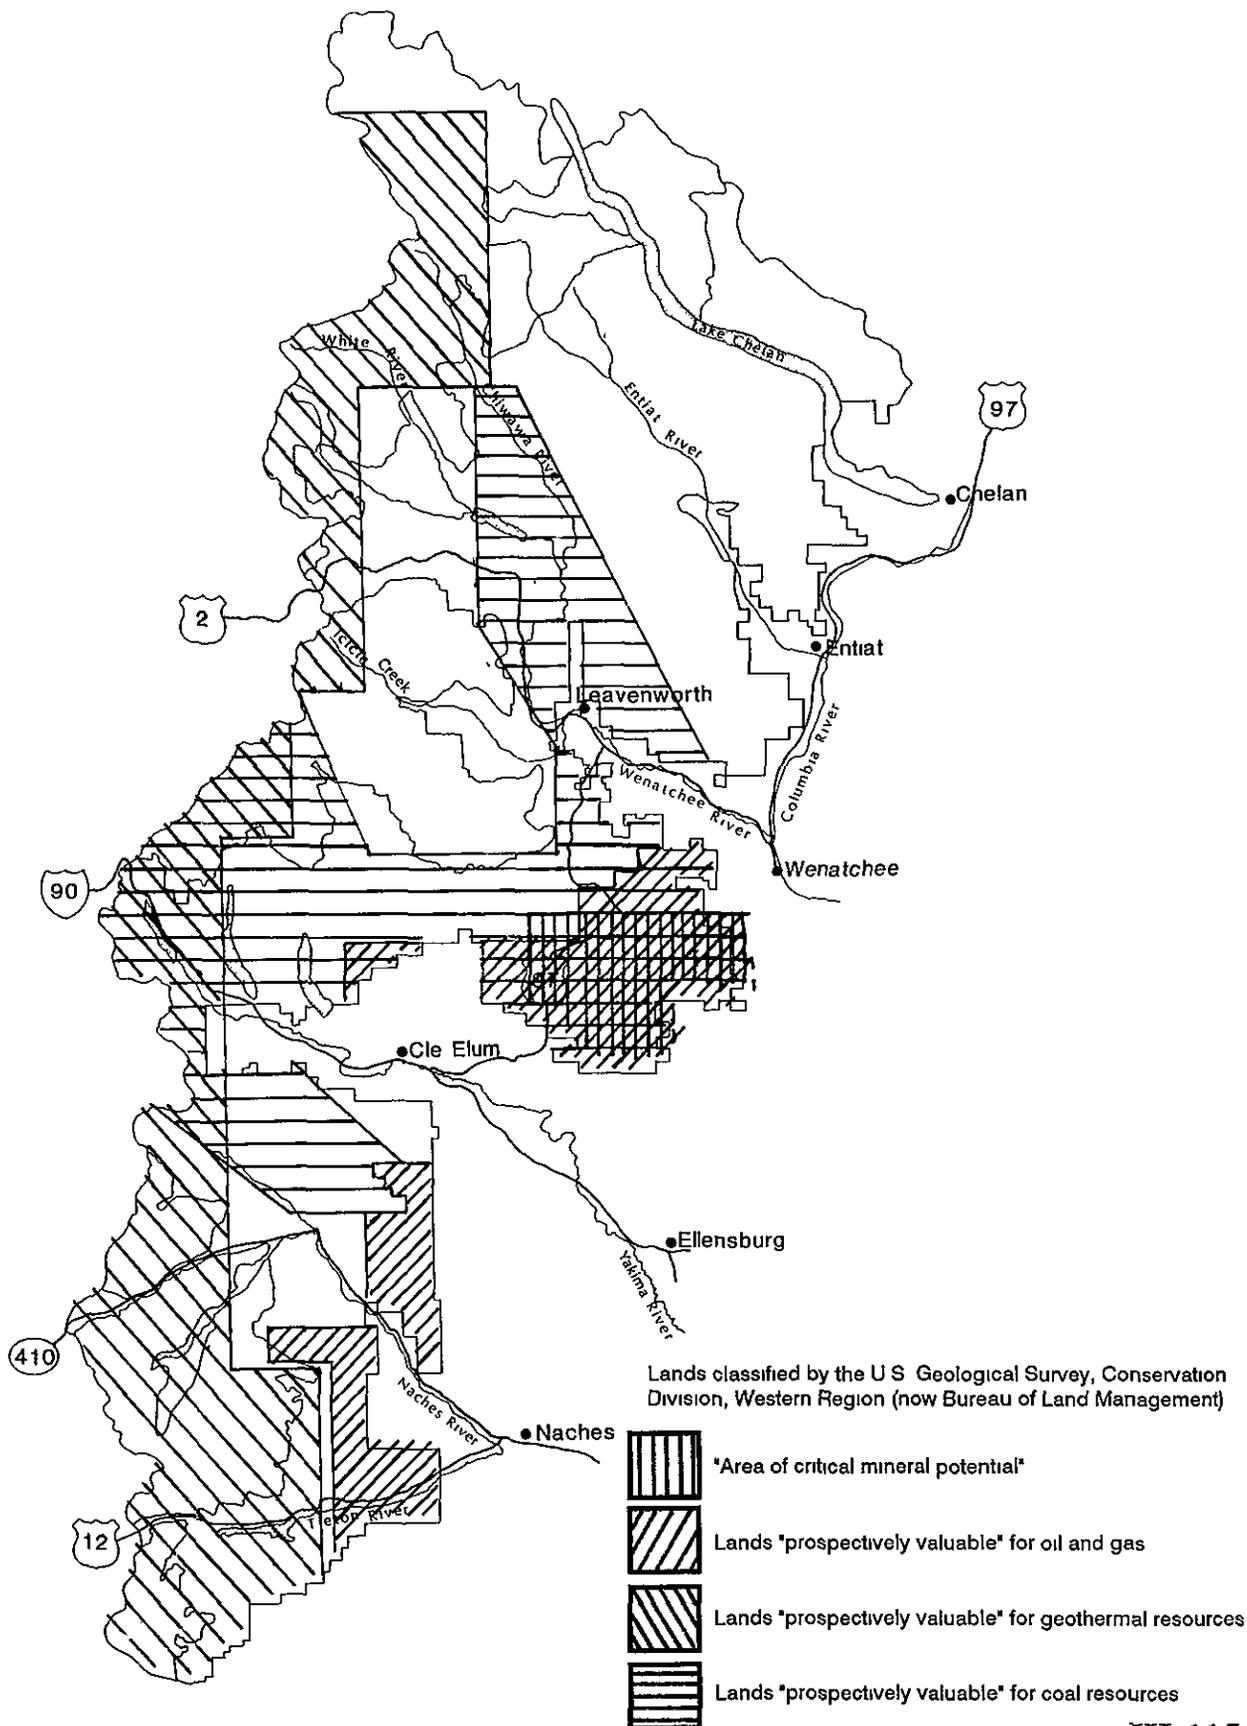

Leasable mineral potential has not been assessed in the same manner as have the locatable mineral resources. Portions of the Forest, however, have been classified by the Bureau of Land Management as being "prospectively valuable" for oil, gas, coal, and geothermal resources (see Figure III-12). Areas classified "prospectively valuable" for leasable minerals are considered to have at least a "moderate mineral potential until proven otherwise." Also shown on Figure III-12 is an area of critical mineral potential which may or may not be for its oil and gas potential.

Statistics updated to November 1988 report that 22 oil and gas leases covering 64,113 acres have been issued on the Forest. The leasing cycle is in a downturn mode and, without some important discovery, it is expected to remain below 200,000 acres for the foreseeable future. Revenue produced from mineral leasing on the Wenatchee National Forest during Fiscal Year 85 was \$215,676 of which \$107,838 was returned to the State. This has declined to approximately \$64,000 this year. This represents rental returns only. Should production begin, royalties would increase this revenue substantially.

Based on available data, oil, gas, and geothermal resources are not known to occur on the Forest in commercial quantities. Barring any significant discoveries, off-Forest short-term activities are expected to remain low and will be dominated by exploration. In the case of geothermal, relatively small scale direct use development is possible, but no large scale development is anticipated.

Although a large portion of the Forest has been classified "prospectively valuable" for coal resources and a smaller area near Cle Elum has been classified as a "coal resource area", it does not appear that their development is likely as long as the more favorable Roslyn field remains available. In response to changing energy demands, however, considerable attention has recently been focused on the production of methane from unmined and unminable coal seams in Washington. This type of development does represent a potential for future use of the coal though it is unlikely to occur within the next ten years.

**FIGURE III-12
PROSPECTIVELY VALUABLE LANDS FOR COAL, OIL, GAS AND GEOTHERMAL**

Disposal of "hard rock" minerals on acquired lands is subject to permit and lease under the Mineral Leasing Act for Acquired Minerals. Presently, only one application has been filed for a prospecting permit on acquired lands, and the Forest has recommended it be issued. Existing permits and this new application lie in areas with "moderate" potential for the occurrence of gold deposits. Pending lease issuance and exploration activities, projecting development of these areas would be speculative at best.

f. Salable Minerals

The Forest maintains a detailed inventory of rock sources which is available at Ranger District offices. It indicates that there are numerous occurrences of various types of rock commodities. Of most interest are the sedimentary rocks. However, there is also considerable interest in the volcanic rocks of the area, especially pumicite.

Although the quality of pumicite is inferior to alternative sources closer to the established markets, several thousand cubic yards are produced annually under permit. The traditional market for pumicite as a lightweight aggregate for casting building blocks is now being augmented by a developing demand for use in preparing potting soils and certain types of insulation. Recent sales indicate a significant upturn in demand in the short-term future. Future sales will continue to be supported by detailed resource inventory and evaluation. The pumicite on the Forest is widely distributed to permit selection of favorably situated mine sites with appropriate regard for environmental factors.

Production of sedimentary-type rocks has dominated the common variety mineral activity over the past few years. The total production of sand and gravel and stone during the period from 1973 to 1980 was approximately 3 million tons with a value of \$6,400,000. The annual average is 365,000 tons valued at \$800,000. Approximately 90 percent of the production was stone. The overwhelming bulk of supply of common minerals is for construction materials in support of Forest Service timber management and State highway construction. In the immediate future, the demand for this resource is expected to lessen in response to reduced road construction activities

associated with timber harvest activities. The demand for county and State highway construction is significant locally, but highly variable in the long term. Future demand for pumicite will depend upon market development in areas not presently satisfied by sources elsewhere. Demand for building stone is almost insignificant, and is not expected to increase significantly because of the inferior quality of the resource and low level of demand for construction purposes.

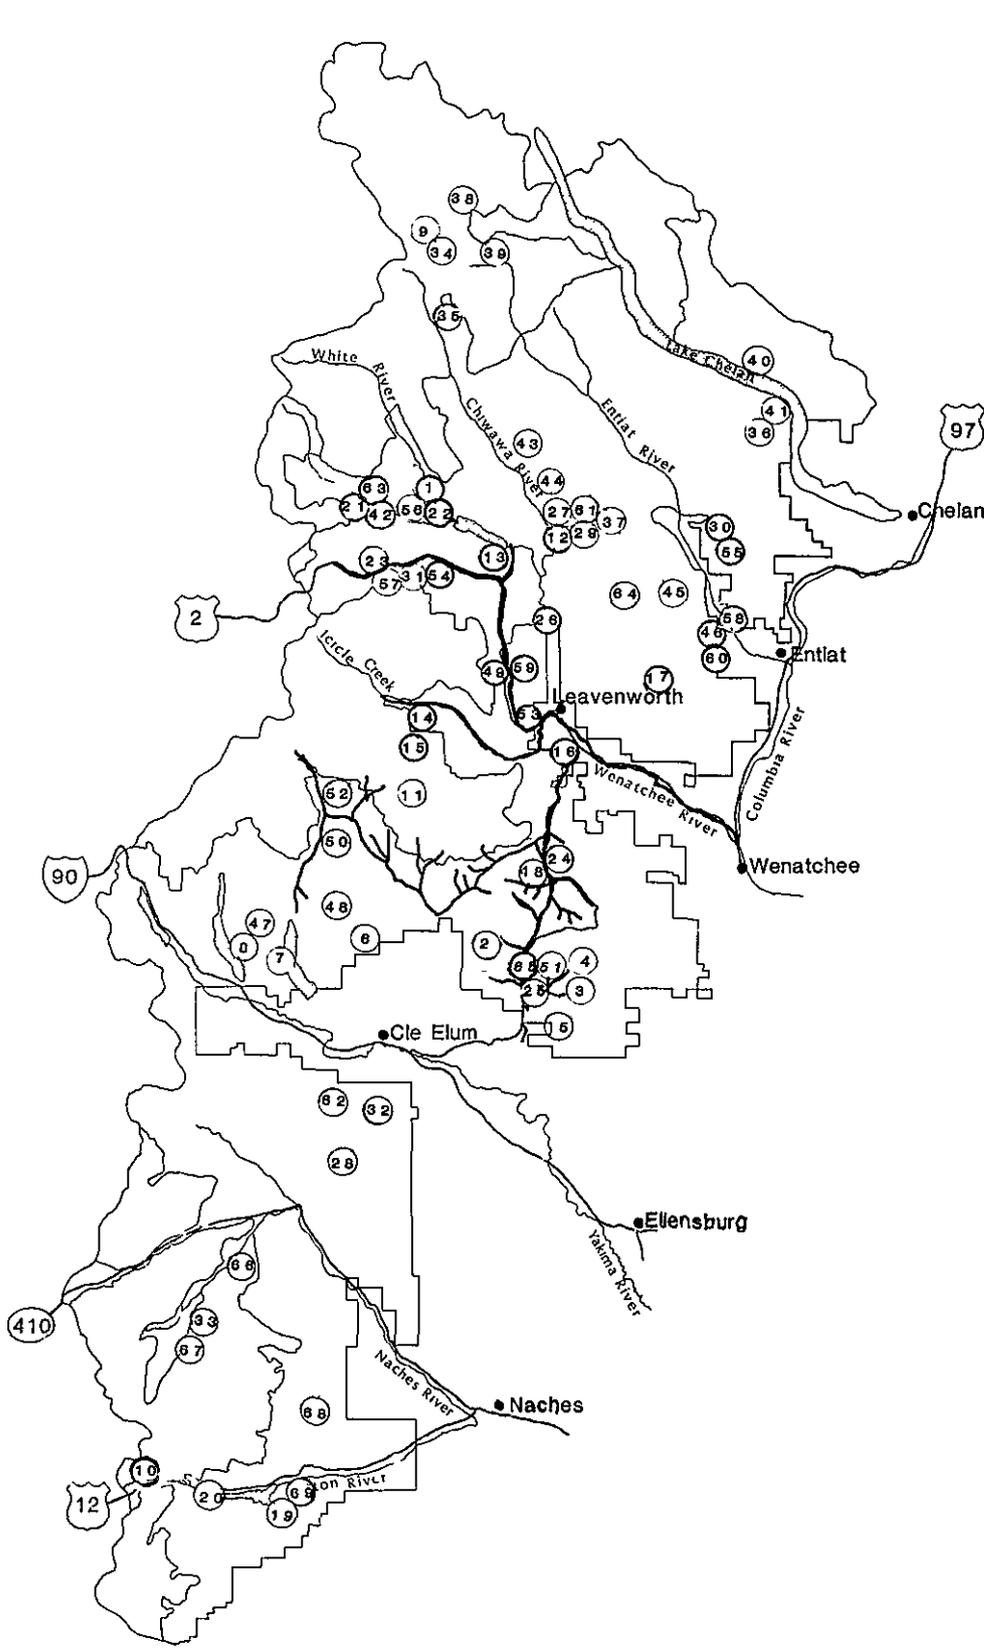

g. Recreational Minerals

(panning, sluicing, dredging, and collecting)

As with the other mineral commodities, recreational type minerals have not been inventoried in detail, nor have panning, sluicing, dredging, and collecting activities been closely monitored. We do know that such activities are continually being conducted, and the level of activity appears to be increasing. We do not know how much material is being removed, nor do we know the value of that material. The activity, which is usually done for non-commercial purposes, does appear to be an important outdoor recreational activity as indicated by the number of participants, the apparent investment in equipment and supplies, and the impact it has on the local economies. Figure III-13 portrays some of the known collecting and gold panning areas (Meschter and Boeing Employees Prospectors Association).

As indicated above, recreational minerals are either removed under the guise of the mining law (mining claims) as a form of prospecting, or, if more than a nominal amount of material is desired or the area is not subject to the removal of minerals under the 1872 mining law, a permit for the removal of such minerals may be issued. Presently, no areas have been set aside to be managed primarily for this type of activity because it is assumed that it can be conducted in a manner consistent with other recreational type activities. However, mining claim conflicts and withdrawals may be a concern because removal of even small amounts of minerals from unpatented mining claims or areas withdrawn from entry under the mining law can be considered trespass. As a consequence, those conducting this type of activity should ensure that the status of the land allows the removal of those minerals in which they have an interest.

h. Supply/Demand Summary

According to U.S. Bureau of Mines data, Washington State ranked 33 out of the 50 states in annual mineral production during 1984 and, in 1987, ranked 20th in non-fuel mineral production. Most of this can be attributed to the increase in precious metal output at the Cannon Mine and in the Republic unit. As a consequence, Washington is ranked 6th in the nation for gold production and 10th for silver production. The Wenatchee National Forest's contribution to that production was minor. Of the minerals produced in Washington, sand and gravel and industrial minerals far exceeded any of the other commodities. Production in the future, however, may reflect a change as several new gold mining operations come on line, including the Cannon Mine near Wenatchee.

Bureau of Mines data indicates the demand for mineral resources will increase at an annual rate of 1.0 to 2.2 percent. As a consequence, locatable mineral related activities (claim staking and maintenance, exploration, development, panning, sluicing, suction dredging, and rockhounding) is expected to remain at a relatively high level through the next 10 years. Should exploration activities being conducted on the Wenatchee National Forest prove positive and mineralization similar to that at the Cannon Mine be identified elsewhere on the Forest, locatable mineral activity will increase significantly. Leasable mineral activities on the Forest are expected to decline somewhat, but exploration for geothermal, oil, and gas resources may increase. Considering the political environment around foreign sources of oil, it is highly likely that those sources could unexpectedly be curtailed. A result of such curtailment would be a significant increase in the oil and gas exploration activity on the Forest. This may also be accompanied by more geothermal and coal activity, since these energy minerals provide alternatives to the use of oil and gas. While the demand for common variety minerals is expected to continue or possibly increase slightly, the Forest Service demand itself is expected to decrease slightly over the next ten years.

i. Land Status

Land status changes (exchanges, disposal, withdrawal) have the potential to affect the availability of mineral resources for future production. The effect of a change in ownership is usually minor, since valuable mineral deposits will generally be developed whether in public or private ownership. Land exchanges do have a potential for removing mineral resources from the benefits of public ownership. However, when land exchanges or disposal actions are proposed, regulations require that mineral potential and appraisal evaluations be completed and the results be considered when determining if the disposal action is really in the interest of the public. The effect of withdrawing lands from mineral entry, on the other hand, can be significant. In the past, withdrawals have been encouraged with little regard for their cumulative effect. The location of withdrawals relative to the location of important mineral deposits and the cumulative effect of withdrawals on the availability of mineral resources in general is of importance to the public's welfare and is of utmost concern to the mining industry.

The Wilderness Act of 1964 authorizes prospecting. However, as of January 1, 1984, or as of the date of the Washington State Wilderness Act of 1984 (July 3, 1984), the minerals in lands designated as wilderness are withdrawn from all forms of appropriation under the mining laws. Valid mining claims perfected prior to those dates may still be operated. As of August 1983, wilderness areas on the Wenatchee Forest had 103 unpatented mining claims. The new wilderness areas established in 1984 include unpatented mining claims as well. Claimants may conduct mining or mining-related activities on valid mining or mill site claims within wilderness areas subject to operating plan requirements. Forest Service objectives would be to ensure that any development project would have as little impact on wilderness resources as possible. There are no mineral leases issued for wilderness areas on the Wenatchee and no new leases will be issued.

The Wenatchee National Forest has additional areas withdrawn from mineral entry for other than wilderness reasons. According to a Bureau of Land Management inventory conducted as of August 17, 1982, the following withdrawals were in effect:

**TABLE III-44
MINERAL WITHDRAWALS OTHER THAN WILDERNESS**

Benefiting Agency	Number	Acres	% of Forest
Federal Energy Regulatory Commission (F.E.R.C.)	20	17,636	0.82
Forest Service	22	7,627	0.35
Geological Survey	9	46,572	2.15
Bureau of Reclamation	5	3,443	0.16
Wilderness (includes lands within the Washington State Wilderness Act of 1984. Does not include the North Cascades N.P., or the Lake Chelan/Ross Lake N.R.A.'s which are managed by the National Park Service)	7	841,034	38.86
TOTAL	63	916,312	42.34

These withdrawals have been implemented for several reasons. The F.E.R.C., Geological Survey, and Bureau of Reclamation withdrawals are usually made to protect reclamation projects or powersite and transmission projects. The Forest Service withdrawals, however, have been made to protect sensitive resources (scenic corridors, research natural areas, special interest areas) or to protect substantial investments made in the land (campgrounds, telecommunication sites, administration sites, etc.).

Review of withdrawals outstanding as of October 21, 1976, is mandated by Section 204 of the Federal Land Management and Policy Act of 1976. This required review is not a part of the current planning process, but all existing withdrawals will be reviewed prior to 1991. Recommendation for retention, revocation, or partial revocation will be made based upon an analysis of the resources being protected and on an analysis of the mineral potential of the area. Where adequate protection is provided by other means or a withdrawal is no longer necessary, it will be revoked or reduced in size. Requests for any new withdrawals will be processed according to Bureau of Land Management regulations and Forest Service guidelines.

j. Reserved and Outstanding Mineral Rights

The Forest includes approximately 3,360 acres (0.15 percent) of reserved minerals, 19,560 acres (0.9 percent) of outstanding minerals, and 10,920 acres (0.5 percent) of acquired minerals. The location of these lands can be obtained from land status plats maintained at Forest Service or BLM offices.

Reserved mineral, which involves those situations where the surface estate was conveyed but the mineral estate was reserved to the United States, generally are subject to the location of mining claims and normal mineral leasing procedures.

Outstanding minerals, which involve those situations where the Forest Service acquired the surface estate but not the mineral estate, are not subject to location or leasing under the Federal mining laws. The Forest Service assumes the role of any other surface owner. Based upon past practice, the surface estate will be managed consistent with the principles of the surface management regulations (36 CFR 228).

k. Access Requirements

Reasonable access is essential to mineral exploration and development. In general, existing forest roads and trails are adequate to satisfy the access requirements for the level of exploration activity conducted during the past 10 years. With several notable exceptions in wilderness, all of the potential mineral areas are served either by existing passable roads or by roads and trails impassable only due to natural deterioration as a result of non-use and lack of maintenance. The exceptions are the Gold Creek, Copper Point, Meadow Creek, and Lyman Lake areas entirely within wilderness areas; and the parts of the Mineral Creek, Fortune Creek, Ingalls Creek, Phelps Creek, Morse Creek-American Ridge, Copper City-Deep Creek, Bumping Lake, and Rattlesnake areas in wilderness.

Otherwise, there are no identifiable major needs for access to any of the inventoried mineral potential areas. Local access needs within areas will be authorized in connection with site-specific activities to be proposed in operating plans.

14. ROADS

a. Overview

About 1905 saw the beginning of railroad logging on the Wenatchee National Forest. The railroad replaced animal and water transport of logs in such places as the Teanaway, the Swauk, and the Wenatchee drainages. Log trucks began to compete with the railroads in the 1920's and, by 1944, railroad logging had ended. Since the 1940's, the majority of Forest road construction has been in support of timber management activities. Today, the harvest of timber puts approximately 127,000 vehicles on the Forest road system annually.

After World War II, the availability of dependable and relatively economical automobiles, easy access to gasoline, and a growing population with increased leisure time, contributed to the growth of motorized forms of recreation. The ownership of private automobiles in Washington State increased from one, in 1900, to over 2,800,000 private cars and trucks today. This has had its effect on the growth and management of the Forest road system.

Through the 1950's and 1960's, the primary road systems were improved and extended in response to the demands of an increasingly mobile public. In the 1970's, concern over the environmental impact of roads, the impact of recreational use on land so easily accessed, and the desire to conserve or preserve the remaining unroaded areas, has all but stopped the growth in mileage of the major Forest roads. The demand on the existing systems is, however, expected to continue.

The automobile is the principal means of travel for most Americans. The Federal Highway Administration has found that 93 percent of the person miles traveled in outdoor recreation are by auto. Other systems (bus, rail, air, etc.) do not have the capacity or flexibility of owner-operated automobiles.

The "National Transportation Trends and Choices of the Year 2000" by the U.S. Department of Transportation 1977, gave a strong indication that automobile use will continue. As the cost of energy increases, people shift to more efficient automobiles. In 1978, 68 percent of new car registrations in Washington were either small or imported cars. According to the Wenatchee Recreation Inventory data, driving for pleasure comprises 12 percent of the total recreation visitor days. This is the second largest recreation activity on the Forest.

Section 10 of the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA) and Section 8 of the National Forest Management Act of 1976 (NFMA) require a "Forest Development Road System Plan." The national direction requires a Forest Development Transportation Plan that consists of a Transportation Inventory System (T.I.S.) and a map. In addition, the National Forests in Oregon and Washington are required to have a Road Management Plan. This plan includes multi-year development plans, traffic management plans, maintenance plans, and interagency road plans. As these plans total 1,400 pages and some 120 maps, they are not reproduced in this document but are available for review at the Forest Supervisor's Office in Wenatchee.

Approximately 33 percent of the total Forest and 53 percent of the non-wilderness acres are considered roaded. In the roaded areas, there are approximately 3.75 miles of road for each square mile of land. Within these sections, the roads actually occupy about 3 to 4 percent of the land area.

In 1988 there were an estimated 5,110 miles of Forest Service roads on the Forest. About 18 percent of this total are classified as arterial and collector roads. Forest arterial and collector roads access large or popular land areas and usually connect with State and County roads to form an integrated network of primary and secondary travel routes. This system is currently 98 percent complete.

Improvements and repairs are needed on the existing Forest road system. Chronic sediment sources need to be corrected, such as the Bethel Ridge Road from the Timber Wolf Road to Cash Prairie. Safe joint use must be provided for the public and timber haulers, particularly along Shady Pass to Halfway Springs, and along the Chiwawa Road to Rock Creek. Improved access to planned development sites is needed to make roads compatible with the sites' development level. Examples are the Icicle Road to Rock Island Campground and the Entiat Valley Road to Cottonwood. Asphalt pavement on some aggregate surfaced roads would reduce the costs of maintenance and dust abatement, such as the Van Creek and the South Fork of the Tieton roads.

About 82 percent of the total system are local roads. These facilities are usually intended to provide access for a specific resource utilization or protection activity, such as a timber sale, a recreation site, or a firebreak. These roads are normally shorter and serve smaller areas of land. Resource service, rather than travel efficiency, is emphasized in their location, design and operation. The analysis of the management situation indicates that the local road system is about 76 percent complete. Ground slopes influence the choice of logging systems and the logging system determines the local road location and density. Typical permanent road densities (miles/Section), necessary to harvest timber in unroaded areas on the Wenatchee National Forest, are 3.12 miles for gentle slopes, 2.64 miles for moderate slopes, and

1.10 miles for steep slopes. Approximately 0.4 mile of additional road construction or reconstruction per million board feet is necessary for subsequent entries. There are approximately 80 to 100 miles of road that are constructed or reconstructed annually.

Bridges

The analysis of the current management situation has identified approximately 35 bridges that will need replacement or reconstruction in the next 10-15 years. These are log bridges that are more than 15 years old, treated timber bridges more than 25 years old, steel or concrete bridges more than 35 years old, bridges whose capacity is significantly (75 percent) less than current legal loads, and bridges where inspection reports indicate significant damage, corrosion, or decay.

Forest Road Management

The National Forest Management Act of 1976, Sec. 8, states that: "roads constructed on National Forest System Lands shall be designed to standards appropriate for their intended uses, considering safety, cost of transportation and impacts on land and resources". The Act implies that no one factor necessarily outweighs the other. Standards must be found for each road section that are appropriate for the intended use and that meet the resource management objectives. Road management objectives for all existing roads have been identified and stored in the Transportation Inventory System. A system has been developed to identify the resource objectives and the appropriate standard and management of all proposed roads.

The current traffic service levels for the arterial and collector systems are shown in Table III-45. Exhibit 1, following, defines the four different traffic service levels for Forest Service Roads. Traffic service levels describe the characteristics that are significant in the selection of road design criteria. They also describe the operating conditions and management strategy that the public can expect to encounter on an individual Forest road. The proposed traffic service levels for the arterials and collectors by alternative are found in Chapter IV.

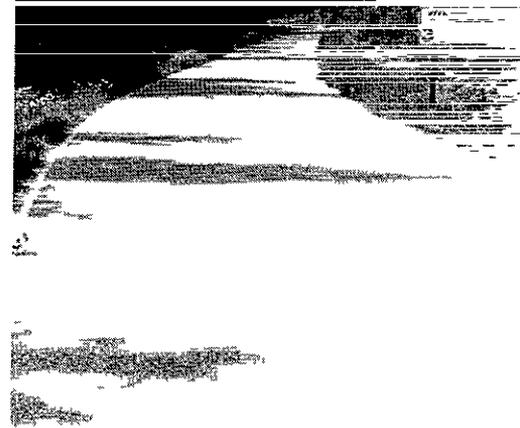

Traffic Service Levels

Free flowing with adequate passing facilities.
Road surface stable and smooth with little or no dust.

Service Level - B

Flow congested during heavy traffic.
Periodic dust control.

Limited passing facilities.
Surface rutting, roughness, and dust may be present.

Service Level - D

Flow is slow or may be blocked
by an activity.
Rutting and dusting controlled
only for soil and water.

b. State Highway System

The Washington State Department of Transportation (W.S.D.O.T.) is responsible for planning, designing, constructing, and perpetuating the public highways of the State highway system for the safe use and benefit of the public. Also, from time to time, the State is responsible for the construction of projects on a county road. The Forest Service Regional Forester has entered into a memorandum of understanding with Washington State. This memorandum establishes procedures for coordinating location, construction, maintenance, signing, avalanche control, drainage control, hazard tree removal, access and other matters related to State highway and Forest highway use and occupancy of National Forest lands. This memorandum is also designed to encompass road construction by the Federal Highway Administration. This memorandum and related maps that display the Forest Highway Systems are primarily for administrative use and are not reproduced in this document. They are available for review at the Forest Supervisor's Office in Wenatchee.

In 1977, the Washington Legislature directed the Transportation Commission to develop a State Transportation Plan (Section 7 (c) and 25, Chapter 151). A copy of this three-volume plan is available for review at the Forest Supervisor's Office. The Washington "Scenic and Recreational Highway Act of 1967" (RCW 47.39) is intended to provide for open space and to protect historic, geologic and scenic resources along transportation corridors. In recognition of those values, all the principle State Highways leading to or within the Wenatchee National Forest have been designated by the State as Scenic and Recreational Highways. They are also identified as State-wide Bicycle Corridors. Following is a brief description of those highways.

Snoqualmie Pass (Interstate 90)

Interstate 90 (I-90) is the major east-west route across the State. There are approximately 17 miles of 4-lane divided highway within the Forest boundary. In 1980, the Forest Service estimated that National Forest activities generated from 4 percent to 8 percent of the total traffic between Snoqualmie Pass and the Cle Elum area. Sea-

sonal traffic fluctuations caused by weekend skiing, hunting, and holidays can cause temporary congestion. The winding alignment and long steep grades near Hyak contribute to this congestion. About 21 percent of the total traffic is truck traffic. Annually, trucks carrying 31 to 50 million board feet of timber from the National Forest enter I-90 between Easton and Cle Elum. Future improvements will include resurfacing, minor widening, bridge repair or replacement, intersection improvements, and other actions to enhance safety.

Stevens Pass (U.S. 2)

Stevens Pass (U.S. 2) is mostly a 2-lane undivided highway. There are approximately 35 miles of U.S. 2 within the Forest boundary. Approximately 21 to 41 percent of the average daily traffic is generated by National Forest activities. Annually, between 16 to 30 million board feet of timber from the National Forest enters the highway on logging trucks in the vicinity of Cole's Corner. About 10 percent of the total traffic on U.S. 2 is truck traffic. Currently the State is planning improvements, including passing lanes.

Blewett Pass (Highway 97)

For the most part, this north-south corridor is located outside the Forest boundary. However, Highway 97 provides essential access (in conjunction with the county road systems) to such popular areas as the Teanaway drainage, Swauk Pass, the Entiat River Valley, Twenty-five Mile Creek drainage, and Lake Chelan. Highway 97 is mostly a 2-lane undivided highway. Approximately 30 miles are within the Forest boundary. In this area, known as Blewett Pass, approximately 5 to 10 percent of the average daily traffic is generated by National Forest users. This route is mainly used for inter-regional travel, and about 18 percent of the total use is truck traffic. Annually, about 9 to 15 million board feet of timber from the National Forest is hauled by truck from the area on trucks around Scotty Creek and the Old Blewett Road. Currently, the Washington State Department of Transportation is constructing passing lanes in the vicinity of Tronson Creek and Bonanza Campground.

Chinook Pass (Highway 410)

Highway 410 is a 2-lane undivided highway. There are approximately 32 miles of Chinook Pass Highway within the Forest boundary. Because of deep snow and potential avalanche hazard, the highway is not maintained for through traffic during the winter. About 18 percent to 36 percent of the average daily traffic is generated by National Forest activities. Annually, about 16 to 30 million board feet of timber from National Forest lands is trucked on Highway 410 in the area around Little Naches and another 15 million board feet between there and the Nile area. Approximately 2 percent of the traffic on Chinook Pass is truck traffic. Commercial truck haul is prohibited to the west at the Mt. Rainier National Park boundary. Currently, the Washington State Department of Transportation, in cooperation with the Federal Highway Administration, is beginning a project to reconstruct the Chinook Pass Highway. The reconstruction will include bridge replacement, guard rails, the addition of passing lanes and the construction of several parking areas and trailheads. Lands adjacent to Chinook Pass Highway have been designated by the Secretary of Agriculture as the Mather Memorial Parkway "for the use and the enjoyment of general public for scenic and recreation purposes..."

White Pass (U.S. 12)

White Pass is a 2-lane undivided highway. There are approximately 29 miles within the Forest boundary. The Forest Service estimates that from 9 percent to 18 percent of the total traffic is generated by activities on the National Forest. Approximately 5 percent of the total traffic on White Pass is truck traffic. Annually, from 16 to 30 million board feet of timber from the National Forest is hauled on White Pass. The majority of this enters between the Tieton Road and Oak Creek. Currently, the Washington State Department of Transportation does not plan any major construction or reconstruction on U.S. 12.

c. County Road System

County road systems are essential for the management of the Wenatchee National Forest. When the county or the Forest Service construct or reconstruct roads adjacent to or within the Forest boundary, the improved access can encourage development on private lands. The residents may bring pressure on the County to provide all-weather access and services that, on a per capita basis, can be prohibitively expensive. These residents may also bring pressure on the Forest Service to manage the adjacent public lands in manner that protects the values and life style that may have originally attracted them to the area.

The legal definition (Forest Service Handbook 7709.16) of a public road is one that is under the jurisdiction of a public authority and open to public travel. In the context of this definition, the Forest Service is not a public road authority and Forest Service roads are not public roads. Forest development roads are roads under the jurisdiction of the Forest Service which are necessary for the protection, administration, and utilization of the National Forest System and the use and development of its resources (Title 23 USC 101, as amended by the Surface Transportation Act of 1978).

Forest development roads can normally accommodate incidental public service traffic. However, the majority of the use may eventually be comprised of traffic from commercial or residential development, or the road may be used for mail, school, or other local government purposes. In such cases, the Forest Service will actively negotiate and encourage the transfer of its jurisdiction to the appropriate public road agency, usually a county.

The Counties and the Forest Service recognize that it is in the public interest to cooperate and to share in the cost of the construction, reconstruction, improvement, and maintenance of certain Forest development roads and county roads.

Chelan County roads provide access to such popular areas as the Icicle, Entiat, and Chiwawa drainages and the Mission Ridge area. The Forest Service and Chelan County have a cooperative agreement that covers some 50 different roads and provides for consultation, maintenance plans, project agreements, rights-of-way, etc.

ROADS

Yakima County and the Forest Service have a maintenance agreement to cover the Tieton Reservoir Road, the Bumping River Road, and the Fontaine Road. The Wenas and Nile Roads are Yakima County roads that provide access to National Forest land.

Kittitas County roads provide access to, among others, Reecer Creek, Manastash Creek, the Te-anaway area, and Lake Kachess. Although there is no formal agreement, the Forest Service maintains the Cle Elum River Road from Salmon La Sac to Tucquala Meadows. The Federal Highway Administration, the Forest Service, and the County are considering reconstructing the Kittitas County road along Cle Elum Lake for some 7 miles to Salmon La Sac.

Title 36 of the Revised Code of Washington (RCW) contains the authorities and direction to the Counties. Those RCW's most appropriate to County roads within the National Forest are:

36.75.070	Highways Worked Seven Years.
36.75.080	Highways Used Ten Years.
36.75.090	Abandoned State Highways
36.75.300	Primitive Roads - classification and designation.

Each County in the State is required to prepare and adopt a comprehensive six-year road program (RCW 36.81.121).

No major construction or reconstruction is planned by Yakima, Kittitas, or Chelan county on roads within or leading to the Forest on the six-year program.

d. Private Road System

Whenever possible or feasible, the Forest Service avoids duplicating existing or planned road systems by negotiating agreements with interested parties to share in the costs of a single system to serve all tributary ownerships.

Currently, the Wenatchee National Forest has share cost agreements with Plum Creek, Boise Cascade Corp., Idaho Pine, Longview Fibre Co., and the Washington State Department of Natural Resources. These agreements cover some 716 miles of road, worth approximately \$27,438,000.

Because of the checkerboard ownership pattern, it is often necessary for the Forest Service or the intermingled landowners to acquire easements or rights-of-way across each other's land. Currently, some 10 percent of the Forest Development Road System is on land managed or owned by others. The acts of June 8, 1897 (16 USC 478) and December 2, 1980 (16 USC 3210) provide for access to non-Federally owned land within the boundaries of the National Forest system. This gives private landowners the right to cross National Forest lands to reach and utilize their property, subject to compliance with applicable rules and regulations. Forest Service regulation 36 CFR 212.8 directs the Forest Service, as promptly as feasible, to grant appropriate access across National Forest land to intermingled or adjacent landowners. Under some circumstances, an environmental analysis is necessary.

15. FIRE

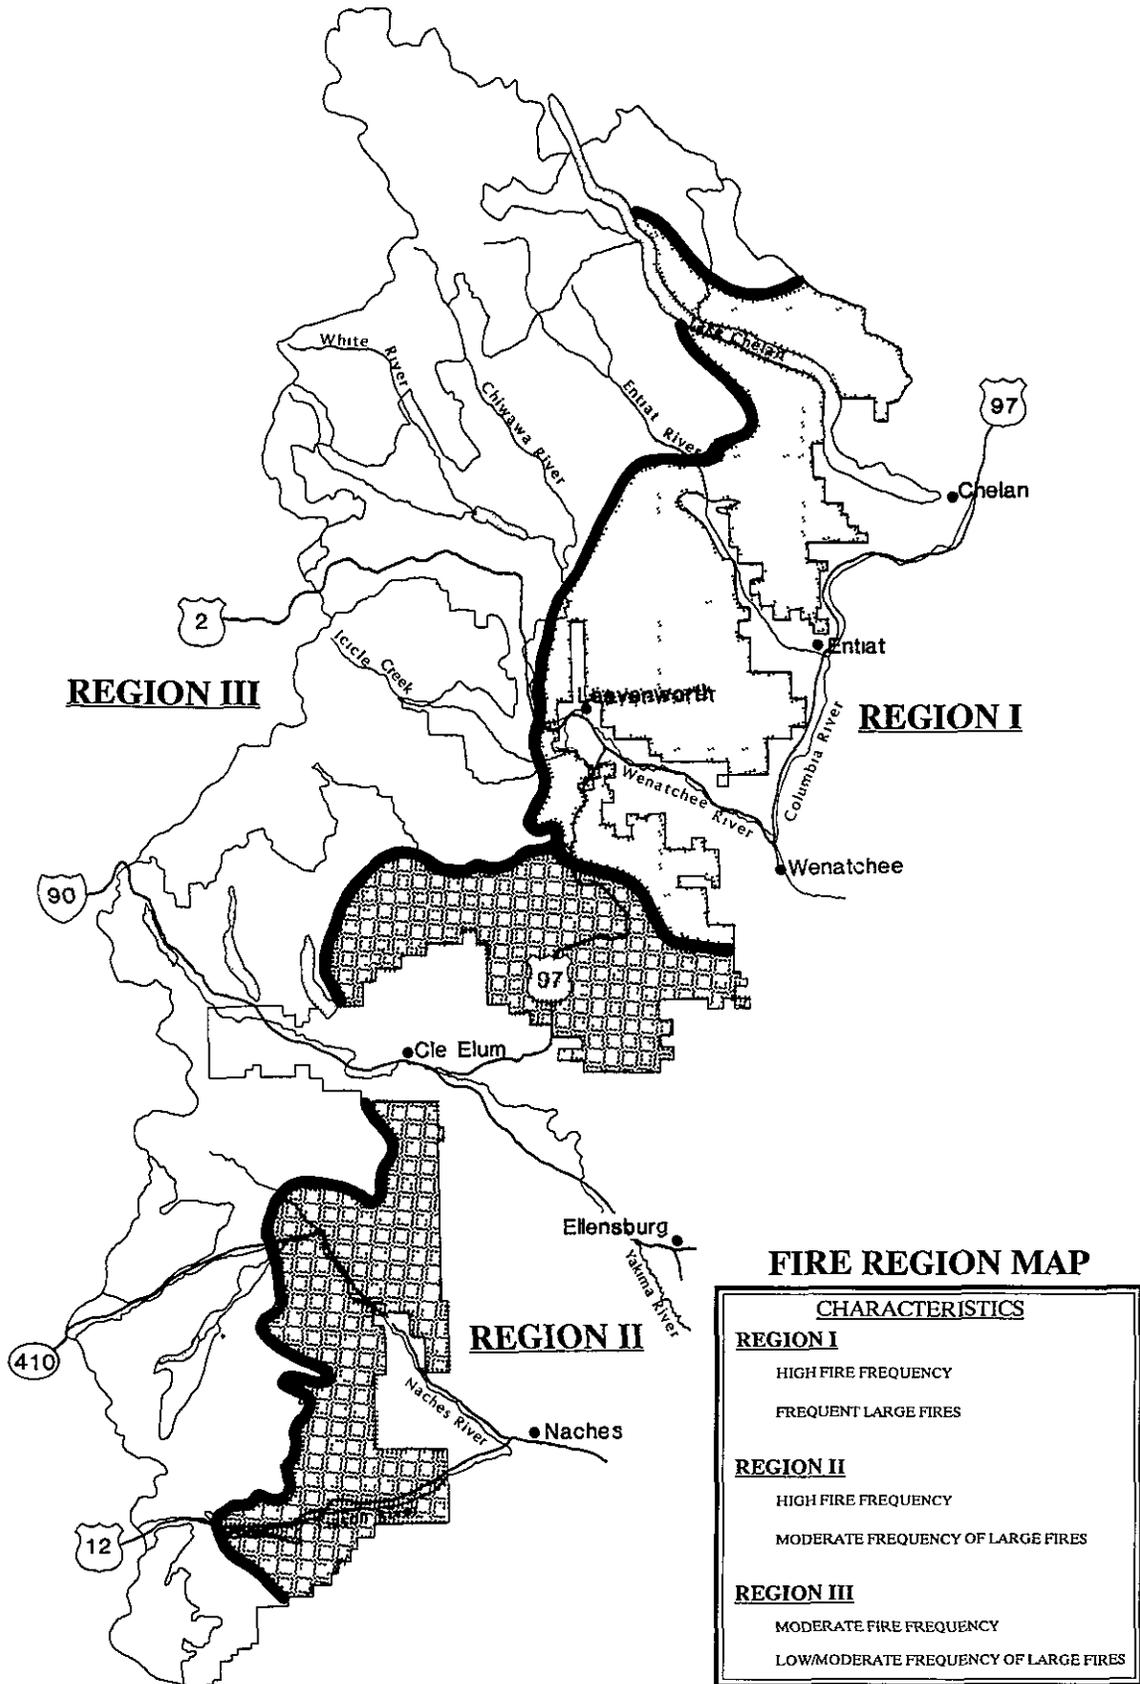

a. Fire as an Ecological Event

Fire is an event that has played an important role in the many ecosystems found on the Wenatchee National Forest. It is an event that varies in frequency, extent, and intensity and is dependent on the climatic, topographic, and vegetative conditions occurring at the point and time of ignition.

The Wenatchee National Forest has a very complex pattern of historic fire occurrence. For purposes of general comparison, dividing the Forest into three regions is helpful in attempting to understand the relative impact of fire on the ecosystems. (See Figure III-14).

Region I can generally be described as the north-east portion of the Forest. The area is located north of Mission Ridge and encompasses the eastern portions of the Wenatchee, Entiat, and Chelan River drainages. Region I has a history of more large fires than the rest of the Forest. Steep topography, extended dry periods, and strong westerly winds have contributed to the occurrence of many large fires in this area.

FIGURE III-14
FIRE OCCURRENCE MAP

Region II is located south of Mission Ridge and lies along the eastern boundary of the Forest in Kittitas and Yakima counties. In this area, the frequency of wildfire ignitions remains relatively high but the average size of the fires is much smaller than in Region I. In Region II, the area is also very dry but the topography is less severe and there are fewer wind-driven fires when compared to Region I.

Region III runs along the entire eastern side of the Cascade Crest. The area exhibits a moderate number of ignitions but, generally, these fires remain small due to the influence of wetter weather from west of the mountains. In this region, there are a variety of topographic features affecting fire behavior, but the moist climatic conditions tend to be the dominant influence on fire behavior.

These general statements about the frequency and size of fires in each region are based on the information available from long-term observations. Within each Region, when climatic conditions are appropriate, the occurrence of multiple fires, or a single large fire is possible. There are no clearly definable boundaries between these regions and the influence of fire in each area has been modified by human activity and resource management practices.

Another contrast that can be drawn between the fires which historically occurred on the Forest can be seen in their effects on the ecosystem. In one instance, a fire will burn very intensely and kill and consume nearly all the vegetation within the perimeter of the fire. This type of fire is referred to as a "Stand-Replacing Fire". On the Wenatchee National Forest, these types of fire generally occur in areas near the Cascade Crest in the true fir, subalpine fir, and lodgepole pine communities. These fires also occur along the eastern fringe of the Forest in the sagebrush, bitterbrush and grass communities.

The second type of fire which occurs is described as a "Stand-Maintaining Fire". This type of fire does not kill all of the vegetation within the perimeter and serves to "clean up" the Forest by removing the build-up of organic debris. Some trees and other plants survive these types of fire and continue to grow and prosper. These fires

occur primarily in the ponderosa pine, Douglas-fir, and larch stands which exist in various locations around the Forest.

Several studies show that the average frequency of fire visiting a specific site ranges from 7-12 years in some of the Leavenworth and Entiat drainages, to well over 300 years in many of the wetter locations near the Cascade crest. Lightning is the only significant natural cause of fires on the Wenatchee National Forest.

b. Human Influence on the Natural Fire Cycle

The influence of human activities on the natural fire cycle on the Forest varies depending on the culture that inhabit the area at the time. When interpreting the frequency of natural fire, the impacts of the Indian culture prior to the mid-19th century must be considered. Before the influence of the European Culture, the Yakima, Wenatchi, and other Indian Nations used fire to enhance their use of the resources. The Indians' huckleberry patches and hunting areas were maintained and improved by removing encroaching vegetation with the use of fire.

With the exploration and colonization of the region by European explorers, a rapid change began to take place. With increased utilization of the timber resource and the establishment of permanent dwellings a period of fire suppression began. Starting in the early 1900's, the Forest Service began an aggressive policy of suppressing all fires. In 1935, a Forest Service policy statement was issued which directed the fire management activities on the National Forests. It stated:

"Fire suppression will be fast, energetic, thorough, and conducted with a high degree of regard for personal safety.... When first attack fails,.... organize and activate sufficient strength to control every fire within the first work period. If the fire is not controlled in the first work period, the attack each succeeding day will be planned and executed to obtain control before 10 o'clock the next morning."

FIRE

In 1972, additional fire planning instructions were issued which specified that suppression capabilities be planned to control fires at 10 acres or less on 90% of the days during fire season.

In 1977, Forest Service Chief John McGuire met with the Regional Foresters to review the National Forest fire policy. A revised fire policy was issued which became effective in February, 1978 and stated:

“The basic fire management policy on National Forest System lands is to provide well planned and executed fire protection and fire use programs that are cost-effective and responsive to land and resource management goals and objectives, and supportive of the 1974 Forest and Rangeland Renewable Resources Planning Act resource outputs.”

Fire policies and the effectiveness of the implementation have varied over time, but the overall effect has been to change the frequency and distribution of naturally occurring fires. The significance of this change depends on the frequency of fire occurrence prior to human intervention. In areas where the fire frequency has been high (less than 20 years), the impacts of human actions have significantly affected the vegetative conditions in the Forest.

Human activity has also increased the number of unwanted ignitions. Man-caused fires now result from a variety of sources ranging from powerline failures to abandoned campfires. Table III-46 displays the fire occurrence on the Wenatchee National Forest from 1957-1985. Table III-47 depicts fires which have exceeded 100 acres for the same period. Both tables show that fire remains a frequent event on the Forest during the typical long, dry, summer season.

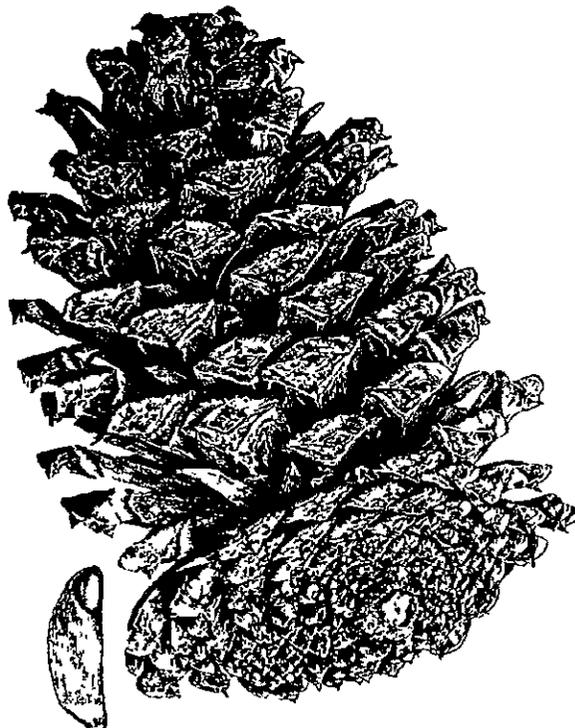

TABLE III-46

**ANNUAL FIRE OCCURRENCES BY ACRES AND CAUSE
1957 - 1985**

Year	Lightning Caused (Fires)	Human Caused (Fires)	TOTAL (Fires)	Lightning Caused (Acres)	Human Caused (Acres)	TOTAL (Acres)

c. **Forest Management/Fire Management**

National Forest managers continue to adjust the approach to managing fire to provide a variety of resources and recreational experiences. One approach is the involvement of the Forest in an active, prescribed fire program. Fire is an excellent management tool when appropriately applied to achieve well defined objectives. On the Wenatchee National Forest, this ranges from the use of fire to replicate the natural fire cycle within the Alpine Lakes Wilderness, to the disposal of logging residues in preparation for reforestation activities. Significant projects have also been implemented to enhance mule deer winter range and to decrease the buildup of organic debris in an attempt to reduce the risk of a wildfire.

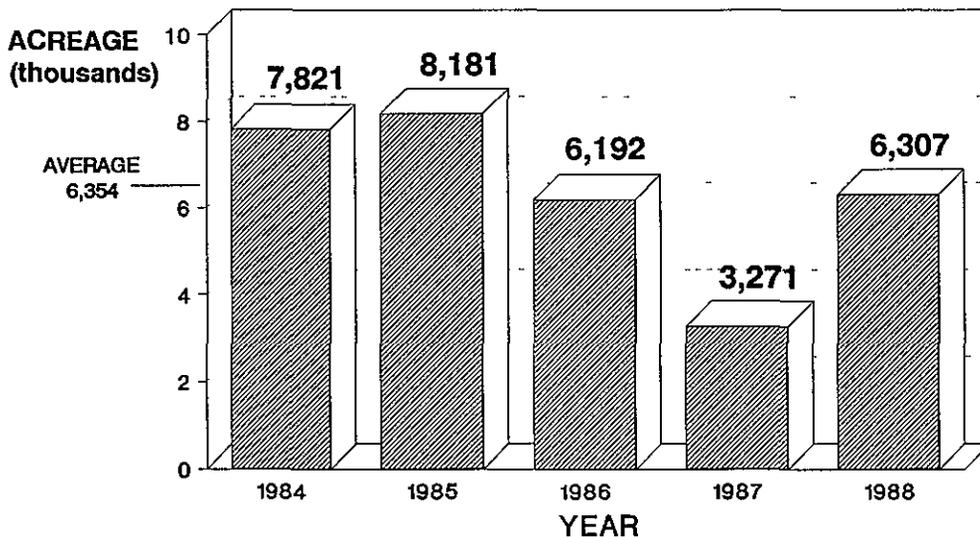

The following chart depicts the number of acres treated by prescribed fire during the past five years.

The second approach to fire management on the Forest involves the suppression of wildfires which are damaging to the resources. The revised fire policy for the Wenatchee National Forest, which was implemented in 1984, mandates that all wildfires be suppressed in the most cost efficient manner. This requires the manager to evaluate

the values at risk and the costs associated with suppression, and to implement a strategy which is most efficient. The development of various computerized models, such as the National Fire Management Analysis System and The National Fire Danger Rating System, have provided additional information on which to base decisions. In addition, the Forest has expanded its reciprocal and cooperative agreements with County, State, and Federal agencies in an attempt to utilize the skills and equipment of all fire suppression agencies in the most efficient manner.

The priorities for fire suppression actions have remained Life, Property, and Forest Resources throughout the century. The major change now influencing our fire suppression efforts is the increased urbanization of wildland environments. This change has made the fire suppression task much more complex and has increased the need for all agencies to participate in Interagency Suppression Activities.

**FIGURE III-15
WENATCHEE N.F. FUELS TREATMENT**

16. SOCIAL/ECONOMIC

a. Social Effects

Community stability is not only an important consideration in selecting a land and resource allocation alternative, it is also a difficult element to describe accurately. Jobs, incomes, receipts, multipliers, etc., are useful but do not portray the total picture, particularly the quality of life aspects.

Communities within and adjacent to the Forest are concerned about a balance of natural and human-related resource activities. Many of the residents of the communities in the area of the Forest derive their livelihood from forest-related activities and many participate in a wide variety of forest recreational activities. These residents have a keen interest in the management of the Wenatchee National Forest.

The recreational activities and environmental amenities offered by the Forest are important components of life in the small rural recreational and residential communities located in and around the Forest. Examples include the Lake Wenatchee area, Leavenworth, and Chelan. Because the economic base of these communities depends on tourism, they are affected by changes

in the pattern of recreational opportunities on the Forest. They are also affected by changes in environmental quality, and benefit from opportunities for free and easy access to forest resources and products. Firewood, fish, game and water are among forest resources important to local communities. The preservation of these Forest qualities is of great importance to these communities.

Rural communities whose economic life is tied to logging, sawmills, and related transportation and construction are also affected by changes in the supply of timber from the Forest. The productive use of resources and products is an important value of Forest management.

Chelan, Kittitas, and Yakima Counties are directly influenced the most by the Forest. Figures III-16 and III-17 portray the relationship of the Forest to the land areas of the counties

In addition to the residents of the three-county area, Forest management affects out-of-area recreationists who live in the metropolitan areas of Washington State. These people enjoy the many recreational benefits of the Forest and are concerned about recreational and visual quality, wilderness, road access, and hunting opportunities.

Figure III-16
Land Area Relationship of Wenatchee National Forest to Counties

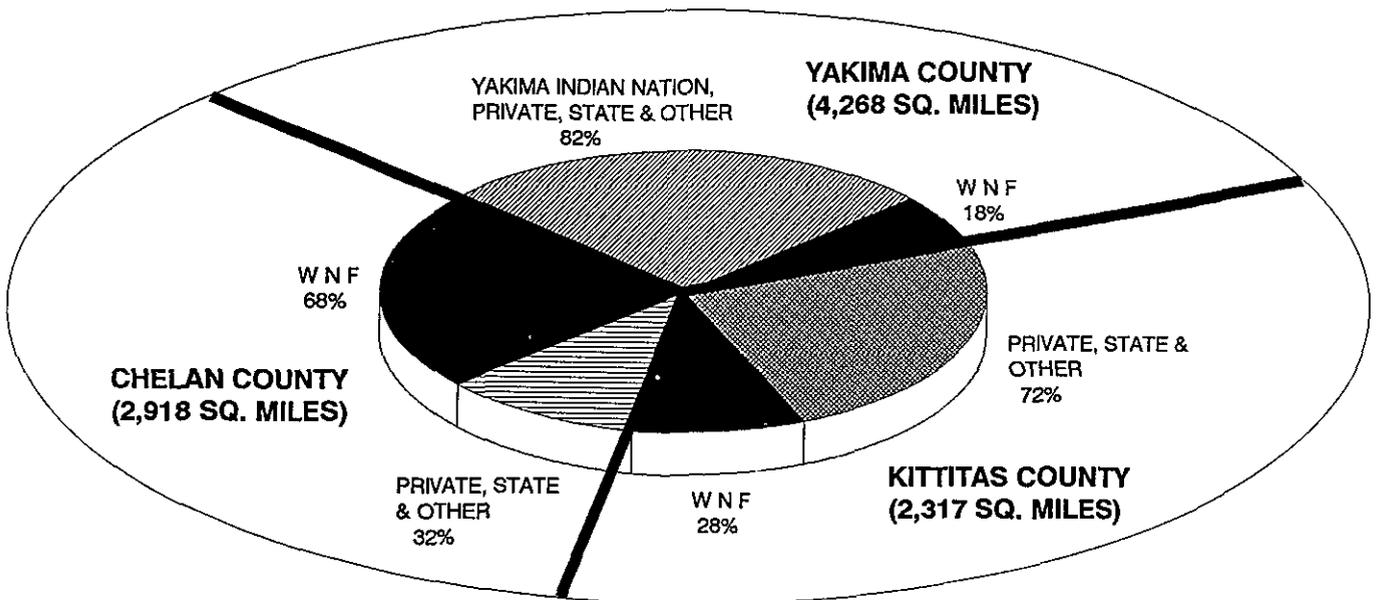

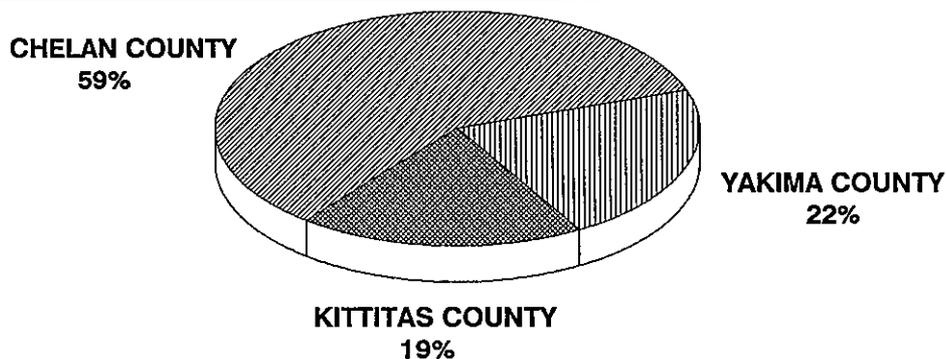

Figure III-17
Physical Location of the Wenatchee National Forest By Counties

A Socio-Economic Overview of the Wenatchee National Forest, updated in 1984, was prepared by the Envirosphere Company of Bellevue, Washington. The overview contains an analysis of the social and economic environment of central and western Washington as it relates to the Wenatchee National Forest. It also presents the analysis framework used, outlines the demography of the region, and presents the economic and social characteristics of the area. The final section portrays the role of the Forest in the zone of influence. The socio-economic overview is available for review at the Wenatchee National Forest Supervisor's Office in Wenatchee. For more information on social/economic analysis, refer to Appendix B.

b. Population

The three counties have an area of 9,503 square miles and a population of almost 250,000 people (see Table III-48). Yakima County is the most densely populated (40 people per square mile) while Kittitas County has the least population density (11 people per square mile). Most people live in the larger towns and cities scattered along the east side of the mountains, especially Wenatchee, Ellensburg, and Yakima. About 90 percent of the people in the three counties live in the agricultural valleys. Residents in the eastside communities are affected by the Forest through availability of recreation, the payments to county governments from Forest receipts, production of market goods such as lumber and beef, and other amenities such as enjoyment of the visual character of the Forest.

TABLE III-48
1983 POPULATION DATA

	Washington	Chelan County	Kittitas County	Yakima County
1983 Population	4,285,100	46,500	24,900	177,000
Percent Urban Population (incorporated areas)		52%	63%	50%
Percent Rural Population (unincorporated areas)		48%	37%	50%
Cities with Population of 1,000 persons or more (in rank order decreasing size)		Wenatchee Chelan Cashmere Leavenworth	Ellensburg Cle Elum	Yakima Sunnyside Toppenish Grandview Selah Wapato Union Gap Granger Zillah Mabton

c. **Economy**

Economic activities in Chelan, Kittitas, and Yakima Counties are tied to the activities of the Wenatchee National Forest. A large proportion of the residents of this area rely on the commodity and amenity resources of the Forest. Economic activities affecting local individuals include logging, sawmill operations, commercial livestock operations, tourism, and various recreational pursuits. Residents of the study area have the opportunity to participate in nearby Forest recreation activities such as hunting, fishing, hiking, and a range of winter sports. These opportunities generate demand for recreation-related goods and services.

The service, government, agriculture, forest products, and construction industries are all important in Central Washington. Because the make-up of the service-related and government sectors is influenced to a large extent by the composition and relative influence of the primary (agriculture and forestry) and secondary (manufacturing and processing) sectors, emphasis is placed on describing the importance of these latter industries in the region.

Employment and income data on Central Washington's economy are presented in the following sections. Additional information is provided on the agricultural sector, the region's most important, forest industries, an important sector that is highly influenced by the Wenatchee National Forest; and the local tourist industry, which is related to the recreation influence of the Forest.

In 1984, 1,575,314 individuals were employed in Washington State. Combined employment for Chelan, Kittitas, and Yakima Counties of 83,872 represented five percent of the State's total work force. Employment data for major industrial sectors in the State and Central Washington counties are presented in Table III-49.

The unemployment rate is an important indicator of the health of a local economy. Due to the relative shortage of jobs in the Forest Influence Zone, the unemployment rates in Chelan, Kittitas, and Yakima Counties were consistently higher than the unemployment rate State-wide (Table III-50). (These data on unemployment are recorded by county of residence, not by county of work place. Data on Chelan and Douglas Counties have been aggregated because these two counties represent one labor market.)

TABLE III-49
EMPLOYMENT BY STATE AND SELECTED COUNTIES (NUMBER OF PERSONS)
MARCH, 1984

	Washington State	Chelan and Douglas County	Kittitas County	Yakima County
Total Employment	1,575,314	20,649	7,216	56,007
Agriculture, Forestry and Fishing	34,865	2,241	---	8,017
Mining	2,426	43	---	52
Construction	69,606	740	128	1,764
Manufacturing	277,895	2,552	531	6,708

In 1984, National Forests in Chelan, Kittitas, and Yakima Counties contributed \$3,593,366 to the Counties for roads and schools (see Table III-51). Of this, \$3,337,750 came from Wenatchee National Forest administered lands.

SOCIAL/ECONOMIC

Per capita personal income data are available for 1970 and 1978 from the Bureau of Economic Analysis (U.S. Department of Commerce, Bureau of Economic Analysis 1980). In 1970, the per capita income in Washington was \$3,997. Personal income in the Forest Influence Zone was lower. Chelan County ranked highest at \$3,665. The 1970 Kittitas County figure was well below this at \$2,975.

Since 1970, per capita personal income Statewide increased by 178 percent to \$11,110 in 1981. The rank order among the three counties has remained constant, but all three registered larger percentage increases than the State. Personal income increased at a rate of 195 percent in Chelan and Kittitas counties, 192 percent in Yakima County. Table III-52 contains data on per capita income for the years 1970, 1978, and 1981.

The economy in the area east of the Wenatchee National Forest rests heavily on agricultural production. Yakima County is the State's leading agricultural county with a diversified farm base. Its principal products include apples and soft fruit, cattle, hops, potatoes, and wheat. The economy of Chelan County depends primarily upon deciduous orchard crops, with apples being the predominant crop. Kittitas is primarily an agricultural county producing crops and livestock.

The Central Washington area is important to the State's economy because of its agricultural base. These counties support 36 percent of the State's agricultural employment with Yakima County alone supporting 27 percent (ESD, 1984).

The agricultural sector will remain the dominant force in the economy of Central Washington. The strong demand for agricultural products abroad as well as the anticipated strength of

domestic demand will, if anything, increase the importance of agriculture in Central Washington. This trend should continue at least through 1990 and may become even more pronounced in the future.

The lumber and wood products industry in the three-county area represented 3.7 percent of the State's employment for that industry in 1983 (ESD, 1984). Yakima County has the largest lumber and wood products work force among the Central Washington counties, with 1,048 workers in 1983. This represented 17 percent of manufacturing employment in the county, and 2 percent of total employment. Chelan County's lumber and wood products industry employed 293 workers in 1983, for respective manufacturing and total county employment shares of 14 percent and 1.5 percent. The lumber and wood products work force of 72 in Kittitas County was much smaller in absolute terms, but still accounted for 17 percent of all manufacturing jobs in the county and 1.1 percent of total employment.

Industries in the three counties accounted for eight percent of the State's timber consumption. Specifically, seven percent of all timber used in the Washington lumber industry was consumed by the seven sawmills located in Chelan, Kittitas, and Yakima Counties. The veneer and plywood industry has a relatively small economic importance in the study area since one mill each is located in Kittitas and Yakima Counties.

The forest products sector of the economy will likely decrease in importance in the future. The extent of this decline, however, will be influenced by several factors. Most notably, the reduction in timber available from private land may cause an overall slump in timber production in the region, and could very likely contribute to a reduction in capacity or closure of local mills. This reduction could lead to further pressure for increasing the harvest from National Forest System lands. This pressure should become particularly intense in the 1990's or earlier should housing demand rebound substantially from its low levels in the early 1980's.

Visitors to the Wenatchee National Forest have an impact on the local economy because of expenditures they make for goods and services. Data on the number of retail trade establishments

are available from the U.S. Census Bureau for States and counties. The variables selected as indicators of local economic dependency on recreational use include the following: 1) hotels, motels, and recreational vehicle parks; and 2) eating and drinking establishments. While these components of the services industry receive a significant amount of business from non-tourists, trends in these two service industries reflect growth or decline in the tourist industry.

In Chelan County, there were 44 hotels and motels and 108 eating and drinking establishments in 1972. In 1983, the number of restaurants increased by 16 percent to 125 and the number of hotels/motels increased by 6 percent to 45 establishments. Most growth has been concentrated in the Wenatchee area. Collectively, these establishments supported about 1,890 jobs, or about 10 percent of total employment in the county. Most of the additions include larger motels and restaurants employing more personnel than in 1972. There were only 1,400 jobs in these categories in 1978.

In Kittitas County, the number of eating/drinking establishments decreased during the 1972 to 1983 period, from 78 to 67 establishments in 1983. The number of hotels/motels decreased from 27 to 19. Total employment supported by these retail and service outlets was approximately 1,020 jobs, up from 900 in 1978, or nearly 13 percent of all Kittitas County employment.

In Yakima County, the number of eating and drinking establishments decreased from 1972 to 1983. There were 44 hotels and motels and 309 eating and drinking establishments in 1983. This decrease is misleading, however, because a number of facilities have expanded their capacity. This is particularly true in the City of Yakima where increased capacity has resulted from attempts to increase convention activity.

A particularly active sector of the regional economy will be the tourism sector. An increase in summer and winter recreation activities, particularly along the major travel routes, is expected. The greatest recreational demand will be near the transportation corridors leading from Puget Sound area population centers. Recreational demand will be greatest in those areas closest to the Everett-Seattle-Tacoma metropolitan area.

d. Social Structure

The social system surrounding the Wenatchee National Forest is characterized by its complexity and propensity for change. The complexity is due to the size of the Forest and its proximity to a major metropolitan area in the Puget Sound region, diverse manufacturing and agricultural communities in the Central Washington region, and recent non-metropolitan growth in the immediate vicinity of the Forest. Change is attributable to rapid metropolitan and non-metropolitan population growth in the Puget Sound region and localized growth in non-metropolitan areas and towns in the Central Washington region.

Intermixed ("checkerboard") land ownership patterns on the Wenatchee National Forest could increasingly become a source of conflict. The expanding set of public goods assigned to National Forest lands by an advanced industrial/social system will be increasingly inconsistent with intensive forest management on adjacent private lands. Forest users and interest groups are likely to become increasingly concerned with inconsistent land uses along these ownership boundaries.

The original migrants to Washington were drawn by opportunities in extractive industries associated with ranching, mining, agriculture, and wood production, as well as the transportation, trade, and service industries which facilitated resource extraction and industrial development (Johansen and Gates, 1957). Farming, ranching, wood production, and some mining provided the primary economic base for the formation of towns along the eastern base of the Cascades. Communities such as Ellensburg, Yakima, Wenatchee, Cle Elum, and Chelan grew in response to markets for basic materials that could be produced from an abundant stock of fertile soils, forage, wood, and coal or minerals.

The populations of these small communities fluctuated with the viability of extraction-based economies. Farming and ranching were relatively stable. Early population growth based upon timber and mining on private land subsided when demand for these resources decreased.

The Yakima River Project brought about the development of irrigation and hydroelectric power beginning early in this century, and may have been the single most important factor in the growth of the region. The economic base established by the Yakima Project and other agricultural development provided the basis for long-term population growth in the region. As agricultural production increased, creating additional activity in processing, distribution and services, small towns such as Yakima and Wenatchee grew into regional manufacturing and service centers. Expanding trade, facilitated by rail and water transport, provided better access to markets for farm products and other regional exports.

Over the last century, the proportion of employment in the primary extractive industries, such as timber harvest and mining, has declined sharply in contrast with the service sector of the economy. The shift in emphasis from resource extraction to services has made recreation and tourism a new economic base for some communities. This shift also places increasing emphasis on public goods such as recreation resources, clean air and water, scenery, and wilderness preservation.

e. Human and Community Resources

The Forest is committed to a nation-wide program of human and community development, which has as its primary goal helping people and communities to help themselves. The program includes activities that provide work and learning experiences for youth, adult employment, training opportunities, and technical assistance to individuals and communities.

The Forest has been actively engaged in a wide variety of manpower and youth training programs. The *Youth Conservation Corps (YCC)* Program provides employees between the ages of 15 and 18 with employment and experience in a natural resources environment. The *Senior Community Service Employment Program (SCSEP)* provides part-time employment for senior citizens whose incomes are within poverty levels. Other programs the Forest has been active in include: The *Comprehensive Employment Training Act (CETA)*, *College Work Study*, and the *Young Adult Conservation Corps (YACC)* Programs.

The Volunteers in the National Forest Program has become increasingly important as funding levels decrease for some of the above programs. This program, authorized in 1972, has been used extensively to accomplish necessary resource activities such as campground host work, trail construction, wilderness patrol, and many other jobs. Many volunteers are highly qualified individuals who are retired or young people unable to find jobs in their profession, trade, or area of interest because of current economic conditions and the lack of employment opportunities. Volunteer programs are expected to increase.

The Forest has the ability to utilize Human Resource Programs to accomplish many forest projects. For example, there is a continuing need to buildings, campgrounds, and trails, to improve young timber stands through thinning and pruning; and to accomplish soil and water improvement programs. Although there is a backlog of projects that can be accomplished, the funding for these programs varies from year to year because of National budget priorities. Because of this, these programs are not always available when needed.

In 1984, the Forest had the following enrollment in these programs:

	Person Years
YCC	2.11
Campground Hosts	1.85
Volunteers	20.72
SCSEP	10.32
	35.00

In the future, these programs are expected to continue at about this same level.

Various programs have been implemented for minorities and women to benefit both the Forest and the individuals. This effort is reflected in Forest Service hiring, supervisory, and contracting procedures.

CHAPTER IV

ENVIRONMENTAL CONSEQUENCES

A. INTRODUCTION

This chapter provides the scientific and analytic basis for the comparison of alternatives presented in Chapter II. The narrative here will discuss the reasons for and results of the environmental effects of the alternatives. It will also present the important effect on interrelationships between resources, land uses, and environmental conditions as a result of the alternatives. In addition, the discussion here will indicate the basis or source of some estimates, and direct the reader to other places in the document where more information on the topic is available.

The net public benefits from the Wenatchee National Forest are obtained from resources with market and assignable prices as well as resources and conditions for which prices cannot be determined. Nonpriced benefits include both quantifiable and qualitative outputs and effects. Quantified and qualitative outputs and effects are both

crucial in understanding the complete picture of environmental consequences and the net benefits to the public. They are discussed here and in the comparison of alternatives in Chapter II. The material in this chapter will explain the relationships between resource outputs and environmental qualities and consequences. It includes, where relevant, the ties between quantitative and qualitative aspects of the information.

Chapter IV is the essential link between Chapter's II and III. In Chapter II the alternatives are presented. The environment those alternatives affect is described in Chapter III. Now in this chapter the consequences of the alternatives on the affected environmental components can be discussed.

This Chapter has six sections:

A. Introduction

1. Changes Between Draft and Final

B. Environmental Consequences of the Alternatives, including:

1. Environmental Consequences of the Alternatives on Each of the Environmental Components

- a. Direct and Indirect Effects of Each Alternative on the Environmental Component
- b. Cumulative Effects of Each Alternative
- c. Alternatives' Conflicts With Other Agency Plans and Policies
- d. Mitigation Measures

C. A Summary of the Relationships Between Short-term and Long-term Productivity

D. A Summary of Irreversible and Irrecoverable Commitment of Resources

E. A Summary of Probable Adverse Environmental Effects that Cannot be Avoided

F. Environmental Conditions Unchanged by the Alternatives

1. Changes Between Draft and Final

The changes between the Draft and Final EIS have been described in each of the previous chapters. These changes have been primarily as a result of public input as well as other agency input.

In discussing the environmental consequences, major changes have been made in the Wild and Scenic Rivers, Wildlife, Fisheries, Soil and Water, and Vegetation components. Roadless Areas and Old Growth have also been treated in the FEIS as

separate environmental components. In addition, the consequences of a new alternative, Alternative J, have been included throughout each environmental component section.

The subject of Wild and Scenic Rivers dominated most of the public input to the Supplement to the DEIS. As a result, several of the preliminary administrative recommendations have been changed.

The Management Requirements (MR's) for old growth/mature dependent species have been considerably changed. Additionally, an expanded section on effects on threatened and endangered wildlife species has been added.

Fisheries is another component revised noticeably, mostly as a result of other agency input.

The relationship of soils and water are so interdependent that they have been combined into a single discussion instead of two separate components.

The topic of biodiversity as it relates to the vegetation component has been expanded substantially in response to public interest in this issue.

Finally, the resource interactions section that had been presented in Chapter III of the Draft has been incorporated into the "Direct and Indirect Effects" section of Chapter IV, under each environmental component.

B. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES

This section discusses the direct, indirect, and cumulative environmental consequences of the alternatives on each environmental component. The conflicts between alternatives' consequences and other agency plans are then described. Finally, mitigation measures will be indicated. Detailed mitigative measures are contained in the Forest-wide and Management Area Standards and Guidelines in Chapter IV of the Forest Plan. In addition, various laws, regulations, and Forest Service direction also provide numerous mitigation measures for National Forest activities.

1. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON THE RECREATION SETTING

The Wenatchee National Forest has an extremely wide range of outdoor recreation opportunities in both summer and winter recreation. These opportunities are available in a variety of forested settings which significantly contribute to the quality of the recreation experiences available to the public. For reasons of both the availability of opportunities and the proximity to large population centers, the Forest receives very high interest and high recreation visitor use.

The Forest Service has initiated a new recreation strategy that places high emphasis on recreation values and opportunities. In all alternatives, recreation has been given major emphasis, and direction has been included in the standards and guidelines to maintain and enhance recreation opportunities as well as to maintain the integrity of the recreation settings.

The recreation setting is the environmental component described within the Recreation Opportunity Spectrum (ROS) classification system. Each ROS class has specific physical, social, and managerial standards which define the recreation setting for that class. Road and trail access, mode of travel, and vegetative alteration through such activities as timber harvest, are the primary factors that affect or change a particular recreation setting.

In each alternative, land use or development activities result in some change in the recreation setting. In addition to timber harvest and road building, the following programs also can result in changes in the recreation setting qualities. mineral and energy development, water impoundment, wildlife and fisheries management, livestock grazing, fire management, timber stand improvement, and recreation developments. Timber harvesting has the potential to create the most dramatic changes in the setting and generally is the principle focus when evaluating the effects of the alternatives on the recreation setting.

Since the degree or extent of an activity varies in each alternative, there is a corresponding variation in the degree of change in the recreation setting. The most dramatic changes are those that go from an unroaded, natural-appearing condition to a roaded, natural or roaded, modified condition. Further development and higher levels of visitor use result in a change to a more rural setting. The number of acres in each ROS class varies by alternative depending on the land allocation emphasis of each alternative.

a. Direct and Indirect Effects of Each Alternative on the Recreation Setting

1) Effects of Recreation Visitor Use on Recreation Setting

The recreation setting, particularly the social component, and recreation opportunities are directly affected by recreation visitor use. As recreation use of a site or area increases, the social setting changes along with the recreation experience available to the users. Some people are not concerned with the changes, others are displaced and seek other less crowded areas on the Forest or in other recreation areas off the Forest. Crowding and over-capacity use levels result in increased social interaction and conflicts, excessive noise, dust and congestion, law enforcement problems and excessive demands on the sanitation and water systems. All of these conditions are key to the quality of the recreation setting.

The alternatives that generate the greatest capacity and opportunities for recreation use will likely have the lowest levels of concentration of users, social interaction and conflict. The recreation sites that tend to be prone to the most social interaction and conflicts are the developed sites and the highly popular, roaded, dispersed areas and associated trails.

Alternatives B, C, D, F, G, I, and J all provide a high level of developed site capacity that exceeds estimated demand and will result in low level impacts on the recreation social setting. Alternatives A/NFMA, E and H also provide for capacity above expected demand. However, some overcrowding and social setting impacts will occur in very popular, high use, developed sites. The capacity for roaded, dispersed recreation greatly exceeds the demand in all alternatives. Social setting changes will only occur in highly popular areas during peak use times such as hunting seasons.

One of the greatest potentials for conflicts between users occurs as a consequence of motorized versus non-motorized use, particularly in the unroaded areas. For some people, ORV use is a disruption of their recreation experience; they feel it creates noise, dust, and impacts to soils, vegetation and wildlife. Others feel the recreation setting should accommodate ORV use, at present or increased levels, and that the impacts are not significant.

Alternatives E and F would offer the highest ratio of non-motorized opportunities, with 16 and 13 percent of the Forest, respectively, allocated in unroaded areas to non-motorized use, and seven percent to motorized use. At the other end of the spectrum is Alternative G, with 13 percent of the roadless areas on the Forest allocated to motorized use, and five percent to non-motorized. Alternatives H, A/NFMA and NC would also provide a higher proportion of motorized than non-motorized use opportunities, with there being no allocation to unroaded, non-motorized use in Alternative NC. In Alternatives B, C, D, I and J there would only be a two percent difference between the motorized and non-motorized use of unroaded areas, with slightly more capacity being offered for both in Alternatives C and I.

2) Effects of Scenery on Recreation Setting

Scenic qualities are a vital part of the recreation setting. A change from an unroaded, natural-appearing landscape to a roaded, heavily altered one, has a direct effect on the recreation setting. The amount of change in the visual quality condition and the Recreation Opportunity Spectrum classes are the best measure of the effects. See Chapter II of this document for the visual quality objectives and Recreation Opportunity Spectrum classes by acreage for each alternative.

The management of viewsheds under Alternatives A/NFMA, C, G, H and I would have similar effects on the recreation setting in different drainages and travelways (see the Scenery section of Chapter IV). Some land allocations prescribing vegetative management would result in an altered to heavily altered setting. Overall, there would be a moderate change in scenery and a reduction of acres providing a semi-primitive setting and natural-appearing condition in these alternatives. Alternatives NC, B, D and J would result in the most change from an unroaded, natural-appearing setting to a roaded, modified setting. Natural-appearing settings would not be retained in most viewsheds. Alternatives E and F would result in the least change in the visual quality condition, and hence to the recreation setting.

3) Effects of Timber Management on Recreation Setting

Timber Management activities have a high potential to alter the recreation setting and the associated recreation use. Timber harvest, site preparation and timber stand thinning or other stand treatments tend to give the Forest a cultured look as opposed to a natural appearance. These activities reduce the wild, primitive and remote feeling for many recreationists and change their overall recreation experience. On the other hand, harvesting of dangerous, decadent or diseased trees in campgrounds and at other recreation sites through timber sales improves safety within the setting. Timber sale activities may be designed to improve trailheads and trail locations, achieve vegetative diversity, and provide openings for viewing scenic panoramas.

Alternatives NC, B, D, and J, which emphasize timber production or commodity outputs, have the largest number of acres in the General Forest allocation and will result in the greatest change in the recreation setting. Alternatives A/NFMA, C, H and I have a more balanced program between commodity and amenity values and fewer acres in the General Forest allocation. These alternatives would result in moderate change in the recreation setting, while providing opportunities for enhancing areas for recreation use. Alternatives E, F and G provide the least acres in the General Forest allocation and thus have the least change in the recreation setting.

4) Effects of Roads on Recreation Setting

The presence of roads has a major influence on the recreation setting and the recreation opportunities available in a specific area. A roaded or unroaded condition strongly influences the use of an area and the means of transportation, the primary recreation activities that are possible, and the number of recreation visitors that are likely to be present. There are some variations in use patterns depending on whether the roads are open or closed to public use. For some Forest users the presence of a road bisecting a trail or being visible from a viewpoint is a reduction in the natural qualities of the recreation setting. For others, a road network enhances the dispersed recreation opportunities by providing motorized access for hunting, for the collection of such forest products as firewood, berries and Christmas trees, or for camping or hiking experiences. The greatest changes in the recreation setting will occur in those alternatives where the most miles of roads are constructed for timber harvest, these being NC, B, H, I and J. Alternatives A/NFMA, C and D will result in a moderate degree of change due to fewer miles of construction, and Alternatives E, F and G which emphasize unroaded recreation, will result in a low degree of change.

b. Cumulative Effects of Each Alternative

The Wenatchee National Forest has a broad diversity of recreation settings and opportunities, with recreation occurring in almost all areas of the Forest at some time through the summer and winter seasons. Because of the proximity of the Forest to large population areas, recreation is a major Forest program. The quality of the recreation setting is an extremely valuable amenity and the maintenance of a variety of settings is very important to the public. The recreation setting is easily managed and is not, for the most part, subject to permanent degradation. However, major changes due to a combination of factors, including road construction, alteration of vegetation, construction of facilities and the effects of fire, insects and disease in forested areas, can produce long term impacts requiring up to 50 or 100 years to repair. The scope of these effects includes all lands in the Forest boundary.

Cumulative effects on the recreation setting can be analyzed on the basis of change in the visual qualities of an area, both foreground and background, the feeling of remoteness or wildness of the area, the natural-appearing qualities of the area and the social conditions. The social conditions include the presence or absence of other people, the interaction or conflicts between users and the type of facilities and developments provided for users. The alternatives which emphasize development of the Forest resources and have the greatest number of acres assigned to intensive management allocations are NC, B, D and J. These alternatives may substantially alter the environment, present a risk of long term modification of the recreation setting and may have a cumulative impact. Alternatives A/NFMA, C, H and I present a moderate risk of long term effects and may also have cumulative effects. In Alternatives E, F and G, the lower acreages in intensive management present the least potential for cumulative effects on the recreation setting.

c. Alternatives' Conflicts with Other Agency Plans and Policies

Washington State Off-Road Vehicle Plan

All alternatives basically support the objective of the State off-road vehicle plan. Alternatives vary only slightly in the acres available for unroaded, motorized recreation, except for Alternative G which emphasizes unroaded, motorized recreation. The roaded recreation setting also provides extensive opportunities in nearly all alternatives. Potential conflict between the motorized trail system and timber harvest will be avoided through measures to protect trails wherever possible.

U.S. Bureau of Reclamation

Any proposed raising of reservoir levels by the U.S. Bureau of Reclamation may conflict with existing or potential recreation developments because of the higher water levels. Scenic objectives of the Forest could be affected by draw-down areas for irrigation or power production. Each proposal will be fully evaluated with regard to the recreation setting. At the present time, none of the alternatives would conflict with U.S. Bureau of Reclamation plans.

d. Mitigation Measures for the Recreation Setting

There is a variety of management actions and practices to apply in mitigation of impacts to the recreation setting. Mitigation can be in the form of implementation guidelines and project design that are to be followed in ground disturbing activities or in projects that manipulate vegetation. In addition, management programs can strongly influence how much impact the recreation users themselves have on the recreation setting. More specific mitigation actions are as follows:

1. Apply the Recreation Opportunity Spectrum Class criteria in all project planning.

Objective: To retain the existing condition of the ROS Classes and to assure that management areas are not degraded to a class more tolerant of change or modification.

2. Design facilities and improvements to conform with setting criteria.

Objective: To prevent high standard facilities from being built in a setting where more rustic facilities would be appropriate.

3. Protect from obliteration dispersed campsites and other specific sites that currently receive repeated recreation use.

Objective: To retain small sites and areas that have significance to specific recreation users.

4. Provide strong public information programs on problems of litter, sanitation, water pollution and damage to soil and vegetation in recreation areas.

Objective: To gain public support and participation in protection of the recreation setting.

5. Provide effective programs in use administration and law enforcement.

Objective: To reduce user conflicts and social impacts on the recreation setting.

Of these management activities, application of the Recreation Opportunity Spectrum and the appropriate design of facilities will provide the greatest benefits to the recreation setting. These mitigation measures should be equally effective in all alternatives.

2. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON UNROADED AREAS

The Forest has twenty-three inventoried, unroaded areas totaling 556,272 acres. This figure includes four unroaded areas that are included in the Alpine Lakes Area Management Plan. The management direction for these four areas is given in this latter plan. However, the 145,476 acres within these areas will be included in the analysis so as to provide a better reflection of the unroaded areas of the entire Forest.

The areas to remain unroaded in the preferred alternative will be managed under one or a combination of the following prescriptions or land allocations:

- RE-2 Dispersed Recreation, Unroaded, Motorized
- RE-3 Dispersed Recreation, Unroaded, Non-Motorized
- RE-4 Dispersed Recreation, Unroaded Timber Harvest
- EW-3 Key Big Game Habitat, Unroaded
- SI-1 Classified Special Interest Areas - Scenic and/or Recreation

The current, unroaded areas proposed for road-ing may be managed under any of the prescrip-tions except RE-2, RE-3, RE-4 and EW-3. The prescription allocation for each area by alterna-tive is based on its resource capabilities and the emphasis of each alternative.

a. Direct and Indirect Effects of Each Alterna-tive on Unroaded Areas

The most dramatic effect of the alternatives on unroaded areas is the construction of roads into these areas for management purposes related to the emphasis of each alternative. The effects will be more or less intensive depending on the acres of the unroaded area accessed and managed for commodity production, and the type of manage-ment prescriptions assigned.

The allocation of unroaded areas by acres for each alternative is as follows:

Alternatives B, D and J result in the largest allocation of unroaded to roaded prescriptions, and consequently generate the greatest effect on unroaded resource conditions. These alternatives place emphasis on commodity production and have high levels of road construction, vegetative manipulation, timber harvest and the greatest change in the ROS classification from Semi-Primitive to Roaded Natural or Roaded Modified (refer to Chapter II, Table II-1).

Alternatives NC, A/NFMA, C, H and I result in reduced change in unroaded resource conditions but still have moderate levels of roading for commodity production. In Alternatives C and I, 54% of the unroaded areas will remain unroaded. The acres accessed will experience the effects of road construction, vegetative manipulation, timber harvest, and other management activities through the life of the Forest Plan.

Alternatives E, F and G place more emphasis on retaining unroaded environmental conditions and unroaded recreation opportunities. The physical, biological and social conditions will vary between alternatives to some degree. Alternative E provides the greatest retention of unroaded acres. Emphasis is on scenery, wildlife and fisheries. Alternative F emphasizes unroaded recreation which will result in more recreation visits or use in both roaded and unroaded. The motorized emphasis of Alternative G would result in greater changes in the social environment in unroaded areas, due to the corresponding increase in noise, traffic and concentration of users that tends to accompany motorized trail use.

**TABLE IV-1
ALLOCATION OF UNROADED AREAS TO ROADED AND UNROADED ACRES**

ALTERNATIVE	NC	A/NFMA	B	C	D	E	F	G	H	I	J
ROADED ACRES	218,022	306,918	327,227	258,157	327,227	106,947	122,263	172,658	306,918	258,157	347,112
UNROADED ACRES	337,250	249,354	229,045	298,115	229,045	449,947	434,009	383,614	249,354	298,115	206,160

1) Effects of Timber Management on Unroaded Areas

Intensive timber management practices in portions of the unroaded areas that are allocated to roaded prescriptions will affect the natural condition of the current unroaded areas. These effects will not be permanent changes, but the altered appearance of managed timber stands will be apparent at least through the life of the managed stands. Changes from natural vegetative growth to managed timber stands will be greatest in Alternatives B, D and J where 327,227 acres to 347,112 acres will be allocated to some degree of timber harvest. Alternatives NC, A/NFMA, C, H and I will have from 218,022 acres to 306,918 acres allocated to some degree of timber harvest and vegetative manipulation.

2) Effects of Roads on Unroaded Areas

The construction of roads will have a high level of impact on unroaded areas. Once roading and prescribed management activities occur the physical, biological and social resource conditions will likely be permanently changed. Even with roads closed to public use, or rehabilitated after management practices are completed, the evidence of human activity will be apparent through the five-decade planning period and probably for much longer.

The following table shows the rate of entry into the unroaded areas. It lists the acres remaining unroaded at the end of first, second and fifth decades:

The rate of entry for road construction and timber harvest will determine the magnitude of the effects in the first decade. These effects generally include:

1. Rapid change in the recreation setting in unroaded areas across the Forest.
2. Increase in heavy traffic and large vehicles on back country portions of the road systems as road construction occurs in unroaded areas.
3. Disruption of recreation activities in unroaded areas and a displacement of users into wilderness or into other recreation areas.

Alternatives B, C, H, I and J all plan entry into a large number of unroaded acres during the first decade. Alternatives B and J have the largest entry at 208,037 acres and 191,862 acres respectively. The effects of entry will be accelerated in these alternatives. Alternatives C, H and I, with an anticipated entry of about 170,000 acres, will have fewer impacts in the first decade than Alternatives B and J.

Alternatives A/NFMA and D, with nearly 140,000 acres entered in the first decade, will be moderate in effect when compared to Alternatives B and J. Alternatives E and G will enter about 110,000 acres in the first decade and Alternatives NC and F have the lowest levels of entry in the first decade, with fewer than 90,000 acres affected.

**TABLE IV-2
ACRES OF UNROADED AREAS REMAINING UNROADED, BY DECADE**

ALTERNATIVE	NC	A/NFMA	B	C	D	E	F	G	H	I	J
1ST DECADE	462,009	417,254	364,410	387,763	410,841	449,325	488,270	438,501	380,707	386,537	348,235
2ND DECADE	417,845	300,698	229,045	298,115	229,085	449,325	434,009	383,614	249,354	298,115	209,160
3RD DECADE	388,250	249,354	229,045	298,115	229,045	449,325	434,009	383,614	249,354	298,115	209,160

For more specific details regarding the consequences of the alternatives on individual, unroaded areas refer to the unroaded area analysis in Appendix C.

b. Cumulative Effects of Each Alternative

Once portions of the unroaded areas are accessed for more intensive land management practices, many activities will follow. Cumulative effects are possible as a result of these repeated activities. Following initial road construction, entries will be made for timber harvest, logging slash treatment, reforestation and timber stand improvement. Other administrative activities will also occur such as fire suppression, timber small sale programs, wildlife or fisheries enhancement projects, public firewood cutting, recreation use (if roads are not closed) and some level of road maintenance. All of these activities may magnify the initial changes resulting from first entry.

The degree or extent of the change can be described in terms of acres converted from unroaded to roaded management, and the emphasis of the alternative which generates the changes. Alternatives B, D and J result in the largest number of acres accessed and all emphasize timber harvest and commodity production. Under this emphasis, there is a high potential for cumulative effects.

Alternatives NC, A/NFMA, C, H and I also prescribe a level of commodity emphasis that will increase management activity on accessed acres. However, there are fewer acres accessed in these alternatives. Although the risk of cumulative effects may be equally high in those areas that are roaded, the area of risk will be smaller than in Alternatives B, D and J.

For the reasons just explained, Alternatives E, F and G do possess a certain degree of risk of cumulative effects, but on even fewer acres of the current unroaded areas. The fact that the emphasis of Alternatives E, F and G are on amenity values and unroaded recreation may result in only a moderate risk of cumulative effects.

c. Alternatives' Conflicts With Other Agency Plans and Policies

Region III State Department of Wildlife

Construction of roads into unroaded areas has an impact on the habitat effectiveness for Big Game animals. Increased access for recreation and hunting may put additional pressure on big game animals and reduce the quality of the hunting experience. These factors could conflict with Department Objectives for the Management of Big Game populations.

d. Mitigation Measures for Unroaded Areas

Mitigation measures for the roading and development of unroaded areas are very limited. The decision to enter unroaded areas for intensive management is a major commitment of resources that will have far reaching and enduring effects.

The primary opportunities for mitigation are centered on how the work is done rather than on the steps to be taken after entry into unroaded areas. However, once roads are constructed, road management can be an important mitigation tool. Closing roads to public use and limiting administrative access to essential visits only, may reduce impacts on soil, water and wildlife resources. Roads could also be rehabilitated or obliterated after use to reduce the effects of entry, although once a road is built, the administrative benefits of continued service are numerous in terms of time and dollars.

High quality transportation planning can be an important mitigation measure in ensuring that road locations and road standards are appropriate for the intended purpose of the road and minimize the associated resource impacts.

In timber sale planning the use of aerial logging systems may eliminate the need for certain roads, thus avoiding the effects of road construction in some areas.

3. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON WILD, SCENIC AND RECREATIONAL RIVERS.

A total of thirty-three rivers and creeks on the Forest were evaluated to determine their eligibility for inclusion in the Wild and Scenic River System. Of these, the American, Cle Elum, Chiwawa, Entiat, Icicle, Little Wenatchee, Napeequa, Wapatus, Wenatchee, and White Rivers were found to be eligible or to have segments that are eligible for inclusion.

Although these rivers possess characteristics that would qualify them for designation, a second aspect to consider in the recommendation for inclusion is the suitability of each river for designation. The suitability would vary by alternative, depending upon the land allocations and potential uses proposed for each of these river corridors, and the degree to which these uses are curtailed or foreclosed by river designation. This analysis might result in some eligible rivers or river segments not being recommended for inclusion, or being recommended at less than the highest potential classification, in different alternatives. In turn, certain river values, such as the visual setting of the corridor, the nature or intensity of recreation use, or the free-flowing characteristics of the river channel could be altered or diminished, depending upon the specific land allocations and treatment of that corridor in each alternative.

a. Direct and Indirect Effects of Each Alternative on Wild, Scenic and Recreational Rivers.

Timber harvest and the related road construction activities would have the greatest effect on the quality of the river corridors. To a lesser degree, recreation development and use may also have an impact. In part, these effects are the direct consequence of land allocations within and along the river corridors, but they may also indirectly result from the designation of a river as Wild and Scenic. These effects are presented in more detail below.

Other factors that could affect river values within the corridors are relatively minor, with little change between alternatives. These include the management of cultural resources, wilderness, wildlife, fisheries, water, soil and fire. However, the impacts created by other activities on these latter resources may have an indirect effect on river attributes through such changes as a reduction in water quality, soil productivity, and available fish habitat; through stream bank degradation; and through a loss of historic or cultural values. Refer to the specific environmental component section of each of these resources for a full description and treatment of the effects.

1) Effects of Recreation on Wild and Scenic Rivers

Water-oriented environments are a strong attraction to Forest visitors, with water-related activities such as boating, tubing, fishing or general water play drawing large numbers of people to these areas. Because of this, river corridors tend to be an intensively managed recreation setting. Developed and dispersed opportunities are maximized, with campgrounds, trails and other facilities often being constructed, upgraded or expanded along the shorelines, and with scenery frequently being maintained to enhance the recreation experience.

For the most part, recreation does not create a direct effect on the values recognized through Wild and Scenic designation. In fact, the recreation setting is often an attribute recognized when determining Wild and Scenic eligibility. Facility development, such as campgrounds, picnic areas, interpretive centers, or administrative buildings could affect the level of classification of a river or river segment if out of scale with the surroundings, but this effect would not vary by alternative. These same developments might also enhance the recreation values of the Wild and Scenic River in cases where recreation has been identified as an outstandingly remarkable characteristic of the waterway.

Of more significance are the indirect effects that might occur as a consequence of public use. Eligible rivers possess attributes that would particularly invite recreation visitors: outstanding scenery, unique natural features, specific recreational opportunities, and oftentimes, an attractive sports fishery. These attributes exist and are managed regardless of whether the river is formally designated or not, but designation tends to increase the recreation use of the particular river corridor. Impacts that can occur as a consequence are conflicts between different types of users, trampling of riparian vegetation, degradation of river or stream banks, an increase in the fecal coliform levels in the rivers or streams, littering, and trespassing on private property. These impacts, in turn, could conflict with the expectations of visitors drawn to the corridors because of the Wild and Scenic designation.

There are no rivers recommended for designation in Alternatives NC, B, D and J. Recreation development and use would probably remain comparable along the eligible rivers through these four alternatives. User impacts would be moderate, and in fact, there might be a decrease in visitors to the corridors because of alteration of the recreation setting by other management activities, especially along the Wenatchee, Chiwawa and Entiat Rivers.

In Alternatives A/NFMA and G, the Wenatchee, Chiwawa and White Rivers are recommended for designation, with 72% of the total river mileage proposed at a Recreational level of classification. A full range of recreation development would be permitted within the Recreational segments, with a correspondingly higher potential for user impacts in these areas.

Alternatives C, H and I recommend nine of the ten eligible rivers for designation, although Alternative H does not include segments with substantial private holdings. Impacts from recreation use, especially as a result of visitors drawn to the area by river designation, could be high. However, there might be fewer conflicts in Alternative H between recreation users and private landowners because of the elimination of private land in this alternative from inclusion in the Wild and Scenic River System.

In Alternatives E and F, all ten of the eligible rivers are recommended for designation as Wild and Scenic Rivers, at their highest level of classification. The effects would be similar to those identified for Alternatives C, H and I, but with the addition of the Little Wenatchee River. Recreation use of the eligible segment of this latter river is currently moderate to low. Designation could increase the number of recreation visitors along the eligible stretch of the Little Wenatchee to a level that might create new and undesirable impacts, if unmanaged.

2) Effects of Timber Management on Wild and Scenic Rivers

Timber management activities can result in a variety of effects to Wild and Scenic River corridors, the most significant being the effect of vegetative management on scenery. Scenery is often one of the outstandingly remarkable values that contributes to the eligibility of a river as Wild and Scenic. It is also an important element in the recreation setting of the river. Through alteration of the landscape by removal of vegetation and construction of associated roads, the natural appearance of this setting can be substantially modified. Loss of large areas of tree cover and vegetative screening, disturbance of soils, and the increased visibility of roads and fire lines may result.

Timber harvest may also indirectly affect Wild and Scenic Rivers through impacts on water quality, fish, wildlife, cultural resources and sensitive ecological values, which, like scenery, are specially recognized values of Wild and Scenic Rivers. These effects are discussed under the individual environmental components elsewhere in this chapter.

The following Table IV-3 indicates the allocations within the corridors of each eligible river for each alternative.

In Alternatives NC, B and D, the scenic values along the American, Cle Elum, Little Wenatchee, Wapatus and Icicle Rivers, which are allocated to a Scenic Travel, Retention prescription below the wilderness boundaries, would be maintained. Segments within wilderness would be subject to the protective restrictions of wilderness designation. However, there could be noticeable modification of the outstandingly remarkable scenic values within the Chiwawa, Entiat, Wenatchee and White Rivers, where portions of the corridors below the wilderness boundary are allocated to Partial Retention and General Forest.

The White, Chiwawa and Wenatchee Rivers are recommended for designation in Alternatives A/NFMA and G, with some segments proposed at less than their highest potential classification. All river values would be fully protected within these corridors. The remaining eligible river corridors below wilderness would be managed for Scenic Travel, Retention, with very little difference in effects on river values from timber management, when compared to those corridors proposed for designation.

Alternatives C, H and I recommend all of the eligible rivers but the Little Wenatchee for inclusion in the Wild and Scenic River System. Values in the Little Wenatchee corridor would be protected through a combination of the EW-1 riparian prescription and a Scenic Travel, Retention land allocation. There would be no significant effects to river values through timber harvest in any of the eligible river corridors.

Alternatives E and F recommend all ten eligible rivers at their highest level of classification. These two alternatives would provide the greatest protection of the outstandingly remarkable values identified in the eligible river corridors.

Another aspect of the relationship between Wild and Scenic Rivers and timber management, is in the tradeoff of timber volume unharvested if river designation takes place. This, more than any other resource allocation, has influenced the suitability by alternative of a river corridor for inclusion in the Wild and Scenic River System. Table IV-4 displays the total timber volume and projected allowable sale quantity (ASQ) by river and by alternative.

3) Effects of Lands on Wild and Scenic Rivers

The types of land uses on the Forest that are authorized for private individuals or public agencies are described in Chapter 3. Few of these would affect Wild and Scenic River designation, and none vary by alternative. However, in the sense that certain of these uses could preclude future designation of eligible rivers, these are discussed as part of the consequences of the alternatives.

One of the factors that contributes to the eligibility of a river, as discussed in Appendix E, is its free-flowing characteristics. Although existing low dams, diversion works, riprap and other minor structures are allowed, the waterway must remain generally natural in appearance and unimpeded in flow to be eligible. New structures are prohibited, particularly the development of hydroelectric power facilities.

In Alternatives NC, B, D and J, no eligible rivers are recommended for designation. Impoundments, diversions or river bank modifications could be permitted that would threaten or alter the free-flowing characteristics and natural riverine environment of the eligible rivers.

Alternatives A/NFMA and G recommend the Wenatchee, Chiwawa and White Rivers for inclusion in the Wild and Scenic River System. Existing structures, such as the Wenatchee-Chiwawa Irrigation Ditch, the Tumwater Dam, and stretches of riprap would be recognized and permitted, but the rivers would be protected from future threats of impoundment or hydroelectric development. However, the remaining seven eligible rivers would not experience this same level of protection.

Alternatives C, H and I recommend nine of the ten eligible rivers. The free-flowing characteristics of all but the Little Wenatchee would be protected. In Alternative H, those segments of the rivers with substantial private holdings would not be recommended for designation, in order to avoid potential conflicts with the private landowners. This would include portions of the Chiwawa, Cle Elum, Icicle, Napeequa, Wenatchee and White Rivers. There would be a higher risk of impoundment or substantial alteration of the river bank in these segments, under Alternative H.

All ten of the eligible rivers would be preserved in their natural, free-flowing condition in Alternatives E and F.

b. Cumulative Effects of Each Alternative

Those rivers selected by Congress for inclusion in the Wild and Scenic River System would be fully protected in all alternatives, with little likelihood for the occurrence of cumulative effects. However, in eligible river corridors not designated as Wild and Scenic, the land allocations prescribed in the selected alternative would be implemented. The nature, intensity and timing of the management activities to be carried out, the overlap of one activity with another, and the effects of activities carried out on intermingled private lands would determine the degree to which cumulative effects might occur, and the specific river values that could be affected. A discussion of the kinds of cumulative effects that might result can be found in the resource component sections for Recreation, Scenery, Fish, Wildlife, Cultural Resources and Vegetation.

In Alternatives NC, B, D and J, the cumulative effects might involve noticeable landscape modifications, including those resulting from intensive timber harvest, the construction of roads and other facilities, and the potential impoundment of the rivers within several of the corridors (the Chiwawa, Entiat, Little Wenatchee, Wenatchee and White Rivers). Over the life of the Forest Plan, the cumulative effects of these modifications could alter the scenic and natural river values to the extent that the affected river corridors would not remain eligible for future consideration under the Wild and Scenic Rivers Act.

Because of the nature of the land allocations within the eligible river or river segment corridors not proposed for designation in Alternatives A/NFMA, G and H (see Table IV-3), cumulative effects are expected to be minimal. In Alternatives C, E, F and I, in which all or nearly all of the eligible rivers are proposed for designation, cumulative effects are unlikely to occur.

c. Alternatives' Conflicts With Other Agency Plans and Policies

The State of Washington is currently conducting an assessment of eighteen rivers in the State which possess the natural, cultural and recreational values that will make them suitable additions to the Washington State Scenic Rivers System. Among these eighteen is the Wenatchee River, from its outlet at Lake Wenatchee to its confluence with the Columbia River. Alternatives NC, B, D and J do not recommend the Wenatchee River above the Forest boundary for designation. Proposed land allocations in the corridor above Tumwater Canyon in these alternatives prescribe Scenic Travel, Partial Retention and General Forest. Modifications to the scenic values along this stretch of the Wenatchee River could directly conflict with the State of Washington objectives for management of the river. In Alternative H, the upper segment is not recommended for inclusion in the Wild and Scenic River system, but the Scenic Travel, Retention allocation of the corridor here would offer nearly the same level of protection to resource values.

d. Mitigation Measures for Wild and Scenic Rivers

The special values for which the ten rivers on the Wenatchee National Forest have been determined eligible for inclusion in the Wild and Scenic River System, will be protected until such time as formal designation is authorized by Congress, or until the rivers are released from further consideration (which, for some river segments, may occur after approval of the Wenatchee National Forest FEIS). The protection zone extends to the adjacent Forest lands, approximately 1/4 mile on each side of each river. Management activities on National Forest lands within these study corridors will be designed to ensure that neither the river nor the corridor are modified to the degree that eligibility or classification would be affected.

Nearly all of the eligible river segments with extensive stretches of private ownership are proposed for designation as Recreational rivers. Present County and State controls should be adequate to protect river values at this level of classification. However, activities will be moni-

tored during the study phase, to avoid direct or cumulative effects to the outstandingly remarkable values or free-flowing characteristics of the rivers.

Measures that would protect outstandingly remarkable river values and reduce conflicts within those corridors designated as Wild and Scenic include:

1. Development of a comprehensive management plan for the river corridor. The plan would address the location and intensity of permitted management activities, the nature and scale of facilities needed, and the kinds, amount and distribution of public use permitted.
2. Monitoring the effectiveness of local laws and regulations of activities on private land within the river corridors against the values for which the various rivers or river segments are designated. In the event that local controls do not appear to provide the necessary protection, initiate discussions with County and/or State agencies to determine the action needed to obtain necessary protection.

These measures would be equally effective for all alternatives where rivers are recommended for designation.

Measures that could be used to protect the significant river values in those corridors outside wilderness that are eligible but not recommended for designation in some alternatives include:

1. The application of management prescriptions which restrict changes in the vegetative and scenic values, so as to preserve these characteristics. This would include locating and designing harvest units to blend with the natural landscape to the extent practicable; designing and blending structural elements (buildings, utility lines, culverts, bridges and so forth) into the landscape to meet visual quality objectives; and designing roads and trails at a level consistent with the adopted Recreation Opportunity Spectrum class and visual quality objectives.
2. Minimize alteration of the streambanks through use of natural materials in riprapping, and by restricting bank stabilization to those

instances where it is necessary for the preservation and protection of existing investments.

3. Evaluate existing developed and dispersed recreation sites to determine if they meet present and future public needs and desires, and if they have the resource capability of sustaining present or future levels of visitor use. Locate new facilities so as to protect the values of popular areas from the impacts of public use.

4. Ensure that recreation facility development or improvement planning is consistent with the applicable Recreation Opportunity Spectrum (ROS) class criteria in terms of the level and scale of development, setting, experience level and social interaction.

5. Monitor or prohibit motorized travel where necessary to protect significant river values.

These measures could be effectively implemented in the American, Cle Elum, Icicle, Napeequa and Waptus Rivers, and in certain segments of the Entiat and the Wenatchee in all but the NC Alternative. Due to General Forest and Partial Retention land allocations in Alternatives NC, B, D and J for the Chiwawa, Little Wenatchee, and White Rivers, and certain segments of the Entiat and the Wenatchee, it would be very difficult to mitigate impacts to the scenic values. At the very least, alterations of the natural landscape in these alternatives might result in a lowering of the potential classification levels of the rivers, if they were to be reconsidered for designation in the future. There is also a possibility that without effective mitigation measures, the outstandingly remarkable values identified in these corridors would be lost.

4. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON CULTURAL RESOURCES

Cultural resources are a unique, fragile and nonrenewable feature of the environment. As such, they are recognized by a special set of historic preservation laws, regulations and policies. Consequently, efforts will be made in every alternative to identify, protect, interpret and manage the significant cultural resources of the Forest.

In addition to the Forest-wide Standards and Guidelines, the SI-2 management prescription will offer protection to most significant cultural resources. However, in order to consider the consequences of the alternatives, all cultural resources have been grouped according to the type of management area allocation surrounding them. The assumption is that these allocations will affect the overall environmental setting surrounding the cultural resources and may impact currently unidentified subsurface materials.

Allocations will also have an effect on management options for future uses of these sites. The SI-2 prescription will not be applied to sites that are ineligible for the National Register of Historic Places. As a result, the nature and distribution of management areas will also affect the total number of cultural resources that are carried into the future.

In all alternatives, the ultimate decision as to whether to practice site avoidance or to carry out mitigation measures in lieu of avoidance will be based on both the nature and uniqueness of the cultural values at the site, and the costs of the desired treatment (avoidance or mitigation).

a. Direct and Indirect Effects of Each Alternative on Cultural Resources

Effects to cultural resources range from disturbance, destruction or loss of part or all of the resource, to modification of the environmental setting around the site such that its basic sense of association, feeling, or place is altered or destroyed. The greater the number of known or

potential cultural sites or use areas that fall within management areas that may create a high level of modification, the greater is the risk of adversely impacting cultural resources.

The alternatives fall into three groupings with respect to similarities in their consequences on cultural resources. A summary of these consequences is displayed in Figure IV-1. These groupings are based on the location and number of acres within each type of management area (by alternative) and on the type of effect that any particular management area allocation is likely to have on cultural resources.

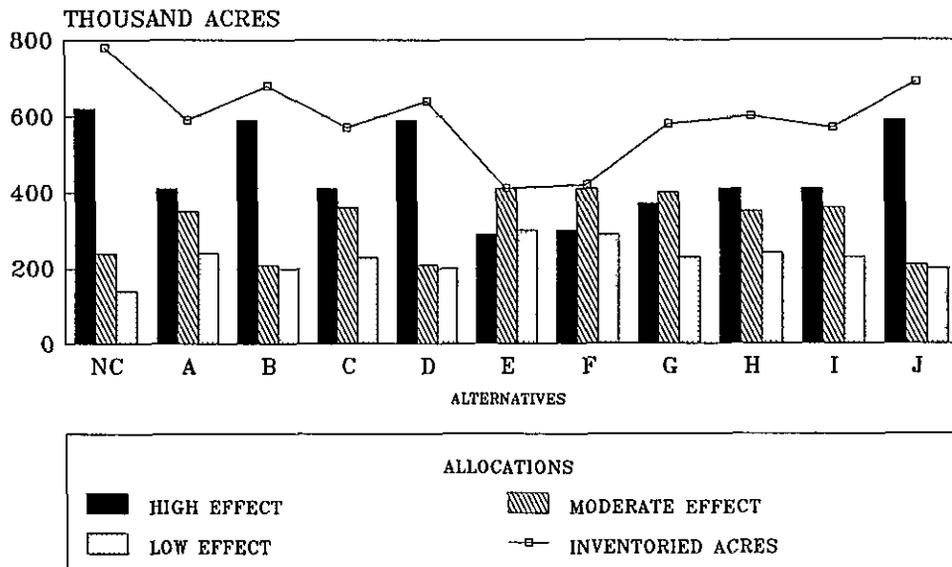

Alternatives E, F, and G overall involve moderate levels of modification to the landscape. The average proportion of known cultural sites and potential or reported cultural use areas that occur within the high impact management allocation areas is relatively low--about 30 percent. However, the heavier emphasis on motorized trail use in the Taneum-Manastash area under these alternatives will create some conflicts with archaeological sites. Although efforts are made to identify existing sites in advance of new trail construction or reconstruction, it is possible to miss subsurface materials that have no surface indications. These sites may later be exposed through ground disturbance or the combination of vehicular passage and subsequent erosion. Once exposed, artifacts and features may be subject not only to breakage or weathering, but also to theft or vandalism.

Other management activities in these alternatives could easily avoid non-significant sites. Visual settings around significant cultural resources would be maintained in a near-natural appearing state, including the area along the historic Naches Trail corridor. Because cultural sites could be managed in place, there would also be available a wide range of interpretive opportunities in the future under Alternatives E, F, and G.

The second grouping of Alternatives is A/NFMA, C, H, and I. Under these alternatives, approximately 40 percent of the known and potential cultural resources occur within management area allocations that may have a high level of impact. Visual settings around some significant sites might experience modification apparent to the viewer, particularly in the historic mining area east of the Liberty Townsite (a National Register Historic District) and near the historic Naches Trail. The long range status of non-significant sites under these alternatives is uncertain. Avoidance in some situations may be impossible. Under Alternatives A/NFMA and C, a majority of significant cultural sites would be managed in place, hence providing for a wide range of interpretive opportunities in the future.

Alternatives NC, B, D, and J, the third grouping, have a considerable potential for affecting cultural resources. Generally, 60 percent of all known cultural sites and potential or reported use areas occur within possible high impact manage-

FIGURE IV-1
CONSEQUENCES ON CULTURAL RESOURCES

ment area allocations. There probably will be noticeable modification of the visual settings around several significant sites, particularly in the historic mining area east of the Liberty Townsite and along the historic Naches Trail corridor. Under these alternatives, it will be impossible to avoid many of the non-significant sites. There may be continuing conflicts between the desire for the protection of cultural resources and other resource management activities, with the corresponding emphasis more on mitigation of cultural resource values than preservation in place. The following discussion addresses those environmental components which may significantly affect cultural resources. These factors will have a direct influence on some management activities, as are described below. There are unlikely to be substantial variations by alternative in the interrelationships and corresponding effects between cultural resources and wilderness, wildlife, fisheries, water, air, minerals, fire, or the social-economic aspects of the environment.

1) Effects of Recreation on Cultural Resources

Where there is an overlap between developed sites and significant cultural resources, there is potential for compaction and displacement of cultural-bearing sediments, as well as loss of cultural resources due to possible vandalism and relic collection. Based on the number of acres allocated to developed recreation in Alternatives A/NFMA, E, and H, these alternatives would have a moderate to low potential for impact. Alternatives NC, B, D, G, and J present the greatest likelihood of impact; Alternatives C, F, and I would have a moderate to high potential for impact. In all situations, the probability of impact would depend upon the nature of the development and its site specific location.

Concurrently, because of the need to protect cultural resources, the development of new recreational sites or reconstruction of existing sites may require advance data recovery, or other mitigation measures. These provisions will probably add to the costs of the recreational developments. Based on the number of acres allocated to developed recreation, the location of these acres, and the nature of the recreational development, the potential for some type of

mitigation is greatest in Alternatives NC, B, D, and J. There would also be a moderate to high potential for cultural resource mitigation work in Alternatives C, F, G, and I, and a moderate to low potential in Alternatives A/NFMA, E, and H. At the same time, several opportunities for historic interpretation in conjunction with developed sites exist. A prime example is Salmon La Sac Guard Station adjacent to the Salmon La Sac Campground on the Cle Elum Ranger District. Interpretation can add significantly to the recreational experience of the user and may ultimately increase the number of visitors to the Forest.

With respect to dispersed recreation and particularly trail construction and use, potential conflicts with significant cultural resources are predominantly associated with those trail systems that are motorized. This is especially true where these overlap with heavier concentrations of cultural sites. In Alternative G the high intensity of motorized trail use may create conflicts with cultural resources. Although there is some potential for the degradation of unrecognized cultural resources, these alternatives will more likely result in the need for an investment in time and funding for cultural resource inventory work, followup site protection or mitigation, and possible relocation or redesign of certain trail segments. This is especially true of those trail segments south of Snoqualmie Pass. In Alternatives C and I the likelihood of mitigation work being required is moderate to high, and in Alternatives A/NFMA, B, D, H, and J it is low to moderate. Only in Alternatives NC, E and F is there little likelihood of recreational trail effects on cultural resources, with the possible exception of motorized trails in the Taneum-Manastash area. Alternatives A, C, G, H, and I will increase public access, dispersed use, and opportunities for interpreting cultural sites to the motorized trail user.

2) Effects of Wild and Scenic River Recommendations on Cultural Resources

The proposed Wild, Scenic, and Recreational River designations in Alternatives A/NFMA, C, E, F, G, H, and I would benefit cultural resources through protection of the visual setting of the river corridors so designated, and by minimizing the extent of ground disturbing activities. These areas tend to support especially dense concentra-

tions of cultural sites. Impacts created by an increase in public use due to the river classification are expected to be minimal. Since there would be no proposed river designations under Alternatives NC, B, D, and J, the benefits to cultural resources that are mentioned above would not be available in these alternatives.

3) Effects of Scenery on Cultural Resources

Since the visual setting around a cultural resource may be a vital component of its significance, alterations of the natural landscape may impact cultural resource values.

Alternatives A/NFMA, E, F, G, and H protect or enhance the majority of the important visual areas on the Forest. This would directly benefit cultural resource values and provide for more compatible management of the visual settings around the significant cultural sites and historic districts.

In Alternatives NC, B, D, and J there will be substantial modification of the landscape. Management activities, such as timber harvest units and roads, will be visible in many areas, detracting from the scenic qualities at those localities. The loss of scenic values will particularly affect cultural resources in the vicinity of the historic townsite of Liberty, along the historic Naches Trail, in the Little Naches, Little Rattlesnake and Rattlesnake drainages, in the Railroad Creek drainage, and in the Chiwawa, Little Wenatchee and White River drainages.

In Alternatives C and I, there would be several viewsheds where the natural-appearing character would be modified. Of concern for cultural resources would be loss of scenic values in the areas adjacent to the historic townsite of Liberty, near the historic Naches Trail, and in the Little Rattlesnake Creek and Little Naches River drainages.

The SI-2 Prescription may be applied to significant cultural sites. Since this prescription prohibits regulated timber harvest, management of some significant cultural sites may help to preserve the visual setting in some scattered locations on the Forest.

4) Effects of Timber Management on Cultural Resources

In Alternative G, 37 percent of the known cultural sites are within high intensity, vegetative management allocations which concentrate on such activities as timber harvesting and regeneration. Potential conflicts with cultural resources would be low to moderate. Obvious alteration of the environmental setting would be minimal for two-thirds of the known sites. Significant sites could frequently be avoided, thereby reducing the potential costs of mitigation or project restrictions.

In Alternatives A/NFMA, C, H, and I, 41 percent of the known sites fall within management allocations specifying intensive vegetative management. Overall, effects would be similar to those identified in Alternatives B and D described below but at a reduced level. This would be due to the scenic classifications along the Little Naches River, along the historic Naches Trail corridor, in the Cougar and Lion Gulch areas, and along the Chiwawa River. The added costs of sale modification, special restrictions or mitigation measures, and more extended consultation would be moderate. Avoidance of significant cultural sites may be possible without major alteration in the timber sale designs.

In Alternatives NC, B, D, and J about 60 percent of the known sites fall within high intensity timber management allocations. Effects requiring mitigation may occur where site avoidance is not possible. These mitigation costs may be substantial, particularly in areas of dense concentrations of archaeological sites such as occurs in the Cle Elum, Lake Wenatchee, and Naches Ranger Districts. There may also be some delay in the timing of vegetative management activities due to the potential for more lengthy consultation with the appropriate historic preservation agencies. The necessity for sale redesign and special restrictive measures may affect a number of the timber sale projects.

In addition, the harvesting of timber under Alternatives NC, B, D, and J might alter the environmental setting of a number of significant cultural resources. Culturally sensitive localities

in the Little Naches drainage, in the Clemans and Bald Mountain area, in the upper Rattlesnake and Nile Creek drainages, in the Taneum-Manastash watersheds, in the Cougar Gulch and Snowshoe Ridge area, and in the upper Chiwawa River Valley could possibly all be affected. A positive benefit of these alternatives would be the potential identification of a large number of cultural resources due to accelerated inventory efforts. Sites that might otherwise deteriorate naturally if unrecognized might have some opportunity for preservation and protection, or at least documentation and recovery of available data.

In Alternatives E and F, less than 30 percent of the known cultural resources are within management area allocations that would have high levels of effect. There would be few conflicts between the management of cultural resources and timber harvest activities. With the emphasis on scenic values in these alternatives, protection of the environmental setting around significant sites would be likely. Costs of consultation, mitigation, and/or project monitoring would be minimal, as would be the likelihood of timber sale restrictions or modifications due to possible adverse effects on cultural resources. The goals of cultural resource management and those of vegetative management are generally compatible in these alternatives.

5) Effects of Range Management on Cultural Resources

Although the supply of forage and the number of structural improvements are anticipated to change by alternative, it is unlikely that the consequences of range management on cultural resources will vary. With the exception of Alternatives NC and A/NFMA, in which the permitted livestock use is predicted to drop, the increase in actual permitted grazing does not vary significantly between Alternatives B, D, E, G, H, I, and J. However, permitted livestock use will remain relatively constant in Alternatives C and F. Since only a small number of structural improvements are likely to conflict with cultural resources, the need for mitigation is expected to be minimal in any alternative.

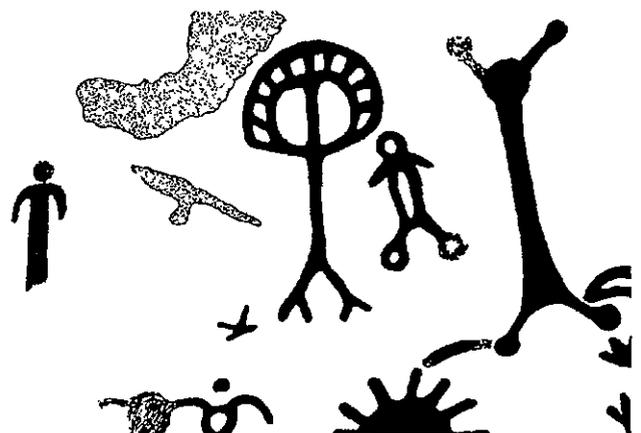

6) Effects of Soils on Cultural Resources

Accelerated soil erosion and/or compaction due to intensive vegetative management may have an effect on cultural resources. Alterations in soil characteristics brought on by timber harvesting and road construction may cause artifacts to be displaced, their contextual relationship lost, and the cultural materials left exposed to weathering agents. Important information concerning past environments associated with the cultural resources in subsurface strata (pollen, seeds, or certain soil constituents or types) is also easily destroyed by processes that degrade the soils. Soil erosion may weaken the structural stability of historic buildings and result in the "sluffing away" of linear features, such as ditches, roads, flumes, and railroad grades.

The consequences to cultural resources due to changes in soils under Alternatives A/NFMA, C, H, and I are difficult to predict, but are not expected to vary substantially from the present situation.

Alternatives NC, B, D and J have the highest likelihood of affecting cultural resources through impacts to soils. This is because of the greater number of acres allocated to soil-disturbing activities within these alternatives. Because erosion is particularly detrimental to archaeological materials, the effects of these alternatives would be most pronounced in the Little Naches and Tieton drainages.

Alternatives E, F, and G will have a minimal effect on cultural resources with respect to soils, because of the limited amount of land allocated to ground disturbing management activities.

7) Effects of Roads on Cultural Resources

The consequences of road construction on cultural resources can be predicted, in part, on the basis of the total miles of construction anticipated under each alternative. However, because roads can frequently be designed to avoid cultural sites, the actual road locations are more crucial in estimating effects than the miles of new construction. Indirect impacts such as increased public access (with the corresponding rise in the potential for vandalism or relic collecting) are probably tied equally to the location of the road and the total miles of road available for use. A positive effect is that roads provide access to carry out cultural resource inventories and can serve as a transportation route to those historic sites and areas that are interpreted and managed for public use.

Potential impacts to significant cultural sites may require more lengthy consultation with the appropriate historic preservation agencies, possible road relocation or redesign, mitigation measures, and monitoring of road construction.

In Alternatives B and J, the high level of road construction increases the likelihood of conflicts with cultural resource values (although the location of the road is the critical factor). Mitigation costs may be high and there may be frequent need for modification of the road design or location, particularly on the Naches Ranger District and in areas east of the historic Townsite of Liberty. Access would be excellent, but the threat of indirect impacts would also be high.

Under Alternatives NC, A/NFMA, C, D, G, H, and I potential conflicts with cultural resources could probably be avoided, keeping project modification and mitigation costs at a moderate to low level. However, the intensity of road construction in any particular area would be the determining factor in how well this could be achieved. Access would be good, and indirect impacts to cultural resources moderate.

The planned level of road construction in Alternatives E and F would be compatible with cultural resource management objectives. Since potential conflicts would be minimal, the necessity of project modification or mitigation would be very infrequent and the resulting costs to the road construction program low.

b. Cumulative Effects of Each Alternative

Many of the cultural resources of the Wenatchee National Forest are unique. They may provide the sole record of a former environment or past way of life. In several instances, the cultural sites of the Forest are also part of a larger complex of past cultures which once extended eastward to the Columbia Plateau and westward to Puget Sound. Each site within this whole is a vital link to the others in interpreting patterns of human use through time.

However, these same sites are also part of a rapidly diminishing, non-renewable resource base. The combination of impacts from past landscape modifications, private developments, natural deterioration, and major hydroelectric projects have destroyed much of this record in central Washington. The exact extent of the loss and the range of site types affected cannot be determined since there was no cultural resource inventory or recordation preceding many of these activities. There are likewise few opportunities today to mitigate the cumulative effects of the past. Once destroyed, a cultural resource cannot be resurrected. This points to the need for even more careful consideration of cultural resource values in the future.

Within the Forest, cumulative effects can be analyzed on the basis of impacts of activities to the visual settings surrounding the cultural resources. Activities may create alterations in above-ground objects, features, and structures, and in the spatial relationships between these; and activities may have impacts on subsurface cultural deposits. The scope of the effects includes all lands within the Forest boundary, including the areas of intermingled ownership, as well as lands within the greater Columbia River watershed. Areas of particular concern include those forested localities where the landowners have clearcut large blocks of land (such as in the upper Yakima drainage) or where landowners anticipate an accelerated period of timber harvest (such as on the Longview Fibre lands in the Stevens Pass Highway corridor and Plum Creek lands within the Cle Elum Ranger District).

The existing cultural resource compliance review process incorporates the consideration of cumulative effects to cultural resources of any proposed action taking place on National Forest land. These effects are subsequently avoided or mitigated through a variety of measures (see the section on mitigation below). However, there is no adequate compensation for the physical loss of some sites. These are resources which, in part, are aesthetically significant - that convey, by their existence in place, a special human link with the historic past - and which are rare because of their tremendous depletion in the past. Since Alternatives NC, B, D, and J have the greatest number of acres assigned to management area allocations that may substantially alter the environment, these alternatives present a risk to these irreplaceable resources. In that sense, these alternatives may have a cumulative impact on cultural resources.

Cumulative effects are less likely in Alternatives A/NFMA, C, H, and I, where the majority of significant sites can be managed in place. Since Alternatives E, F, and G present few conflicts between significant cultural resources and other management activities, they have the least potential for cumulative impacts on cultural resources.

c. Alternatives' Conflicts With Other Agency Plans and Policies

The Washington State Office of Archaeology and Historic Preservation (SHPO) is presently preparing a State-wide Preservation Plan for cultural resources. Since it is in the preliminary stages, potential conflicts between the effects of the Forest management alternatives and the objectives of the plan cannot be determined.

Representatives of the Yakima Indian Nation and the Confederated Tribes of the Colville Reservation have expressed a continuing concern for and interest in the Forest management of cultural sites. This particularly includes those sites which represent traditional use areas or to which members of the tribes have ancestral ties. In every alternative, there would be coordination of proposed project actions with the American Indian community to try to resolve any potential conflicts that might arise.

d. Mitigation Measures for Cultural Resources

Mitigation most often involves the use of methods or techniques that will minimize disturbance to cultural resources and their environmental setting. A variety of potential mitigation measures exist. These may range from special project design criteria to be followed during ground disturbing activities, to protective enclosures or exclosures around significant cultural sites, to systematic monitoring of project activities. Each would require further consultation with the SHPO and the Advisory Council on Historic Preservation if the resource is determined eligible for the National Register of Historic Places. The most desirable measures, of course, are those which effectively protect the cultural resources in place, are economically prudent, and are compatible with other resource management needs.

Some of the more commonly used mitigation measures include:

1) Adjustment of project boundaries to completely avoid cultural resources and minimize alteration of the environmental setting.

The most important step in preservation and protection is systematic inventory well in advance of Forest management activities. Proposed roads, trails, timber sale units, and other project boundaries can generally be adjusted without additional cost or inconvenience, if the need is determined during the very early planning stages of the project. This eliminates impacts or threats to cultural sites while encouraging "business as usual" with respect to other management activities.

2) Adoption of methods or techniques that will minimize disturbance to cultural resources and their environmental settings.

Frequently, activities may be carried out around a cultural site with minimal disturbance through creation of a protective buffer zone, through use of special technologies, or through reduction of the actual area of ground disturbance. Since the most common interaction of cultural resources with other management activities on the Wenatchee National Forest is with timber harvesting, a series of examples of this type of mitigation measure as it pertains to timber management follow:

a) Use of an aerial or full suspension yarding system.

Full suspension substantially reduces or avoids disturbance to the ground surface (Marvin, 1982). This has been an effective procedure on the Forest, although there are some visual effects created by the skyline corridors. Full suspension of the logs in combination with directional felling of trees away from the cultural site, and monitoring of the harvest activities by trained cultural resource technicians, can afford nearly full protection to the cultural resource. The nature of the timber sale design will determine the degree of effect on the visual setting of the site. Careful planning and a clear understanding of visual quality objectives around the cultural resource will minimize adverse impacts.

b) Where tractor logging is necessary, restriction of the overall number of skid trails and designation of a planned system of trails to reduce impacts. In previously harvested areas, reuse of existing skid trails wherever possible.

These measures could be applied to avoid cultural sites, although obviously there would be an effect on the visual setting. The concept of designated skid trails has been successfully tested in soil compaction studies (Froelich et al., 1981), but the concept is likewise applicable to cultural resources.

c) Use of a buffer between equipment and the ground surface.

This measure may be suitable where there are no above ground structural remains. Recent studies on the Winema National Forest have tested the concept of logging over snow as an effective method of protecting cultural resources (Philipek,

1985). The results indicate some success as long as the soil characteristics, snow depth and moisture content, slope, and air temperature meet certain criteria. The location of the landings, the method of subsequent slash piling, and careful administration of the timber sale contract to see that specialized criteria are met, are crucial to the success of this technique.

Frequently it is necessary to construct or reconstruct roads to access the timber sale areas and to provide suitable haul routes for the logging traffic. On occasion, it is impossible or economically unrealistic to completely avoid a cultural site. If environmental circumstances allow for flexibility in the road design, disturbance might be minimized by avoiding excavation of the road bed and instead providing a layer of plastic filter cloth and fill between the road surface and the ground surface. Trees removed within the right-of-way might be flush cut and the stumps left in place, to further minimize soil disturbance. This method was used on the Mt. Baker-Snoqualmie National Forest in 1981 during reconstruction of the Huckleberry Mountain Road 195C on the White River Ranger District, and was well received by the Advisory Council on Historic Preservation during the compliance review consultations (Hanna, 1980). Future test excavations below the road surface will be necessary to determine just how successful this method was in protecting the subsurface cultural deposits.

This concept of protective capping of a cultural site (where there are no above ground structural features or remnants) by crushed aggregate or other materials may apply as a mitigation measure to a wide range of management activities.

3) Removal of the cultural (historic) property to another appropriate location (if physically possible) after adequate documentation of the property and provisions for protection of its historic values and integrity.

The first consideration in moving a property is to find an alternate and similar locality on the Ranger District or Forest in which the cultural resource occurs. Alternatively, the resource could be transferred to private ownership for future protection. This method of mitigation has not been common in Region 6, but was successfully carried out on the Rogue River National Forest

with the McCredie House. That site was a National Register property, originally situated within the J. Herbert Stone Nursery, but sold with protective covenants and moved to private land in April 1985.

4) Mapping, photo documentation and scaled drawings of the cultural resource (historic properties only) before proceeding with project implementation (and loss of the resource).

In this situation, loss of a cultural site can be mitigated through recovery of as much of the information contained in the property as is appropriate, considering the nature of the resource and the impacting activity. Normally, this documentation is done to the standards of the Historic American Building Survey (HABS) or the Historic American Engineering Record (HAER), whichever is applicable. This may involve historic research, mapping, photo documentation, and measured drawings. This process was successfully used by the Wenatchee National Forest in advance of the sale of the historic Liberty Townsite to private ownership in 1981, and is one of the more common mitigation measures preceding the removal of historic properties. In the case of linear features, such as historic ditches, wagon roads, highways, railroad grades, and so forth, a combination of thorough documentation of the feature with preservation of a designated segment might be acceptable.

5) Excavation of archaeological resources utilizing a professionally sound research design in keeping with the State-wide Preservation Plan.

Such excavation would be undertaken through an outside contract that has a research design approved by the State Historic Preservation Office and the Advisory Council on Historic Preservation. When determining whether this is an appropriate mitigation measure, four criteria should be considered:

a) Does the significance of the property lie primarily in the data it contains? In the case of archaeological sites, consideration of the cultural/religious concerns of the American Indian community is vital to the decision.

b) Would preservation in place be more costly or less practical than data recovery?

c) What is the scope of the proposed project or undertaking in relation to the size and nature of the cultural property (i.e., is all of the site, or just a small portion of it, involved)?

d) Would the cultural property be subject to other agents of degradation or disturbance, such as vandalism or uncontrollable erosion, regardless of any proposed undertaking which might affect it?

In addition, it must be determined whether the data contained in the site can be used productively to address valuable research questions, and whether the available time, funding, technology, and expertise are adequate to recover the significant information. As to how much data recovery is sufficient, there is no standard. The nature of the data recovery effort, its scope, and its boundaries must be determined on a case-by-case basis.

The specific mitigation measure chosen to avoid or lessen project impacts will depend on the nature of the cultural site and the project activities proposed. Some of these measures may also be used in combination.

5. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON SCENERY

a. Direct and Indirect Effects of Each Alternative on Scenery

Resource components and management activities that have a similar effect on scenery in all alternatives include the development of structures and facilities, air quality, and wildfire. Structures of all kinds create visual dominance within the natural, forested environment. The placement, size, and number of structures and the degree of contrast creates changes in form, line, color, and texture. Structures can occur in many areas. They may be utility lines and corridors, fish ladders, small dams, walls and riprap, buildings, microwave towers, ski areas, signs, and facilities in campgrounds and at trailheads.

Clean, smoke-free air will provide a crisper depth of perception, and allow for visually appealing, natural forest viewing along travelways and at vista points. Wildfire can create large acres of blackened forested landscape in contrast to the green texture of an unburned landscape. Associated with wildfire is smoke, haze, dust and other particulate matter, which reduces visual perception.

The effects of specific resource management activities on scenery which vary by alternative are vegetative manipulation for wildlife, timber management and the associated road building, prescribed fire and shaded fuelbreaks, and forage for range management.

1) Effects of Wildlife Management on Scenery

Vegetative manipulation of wildlife habitat to achieve a forage-to-cover ration of 60/40 for deer and elk increases openings that will dominate the naturally-established landscapes. The openings create new form and rearrange the landscape to an altered appearance. Wildlife viewing may increase as a result of the change. The more land allocated to this activity, the greater the alteration of the landscape.

Alternatives that will have the least to most visual impacts to scenery as a result of wildlife management are listed below. Alternatives E and F allocate approximately 40,000 acres to Big Game habitat followed by C and I with approximately 48,000 acres. H and J allocate approximately 52,000 acres, with Alternative A/NFMA allocating 54,000 acres and B and D being the biggest impact with approximately 58,000 acres.

2) Effects of Timber Management on Scenery

Timber harvest levels, especially those resulting in clearcuts, have the greatest effect on scenery. The more vegetative manipulation that takes place for timber harvest, the greater is the size and amount of disturbance that could create visual alteration to the landscape. The contrast of form, line, color, and texture patterns created by timber harvest can change the natural-appearing landscape to an altered or heavily altered one.

In addition, the more intensive the management of timber for commodity production, the greater

potential there is for smoke from burning and for haze, dust, and other particulate matter to reduce visual quality.

Steep slopes, soil color contrast (light colored soils), and low soil productivity have the biggest effects on the visual absorption capacity (VAC) rating because this combination of factors would produce a low VAC rating. The effects vary by alternative because the intensity of ground disturbing activities, particularly those resulting from timber harvest, vary by alternative. The more ground disturbance there is within an alternative, the bigger the effect will be on the scenery resource.

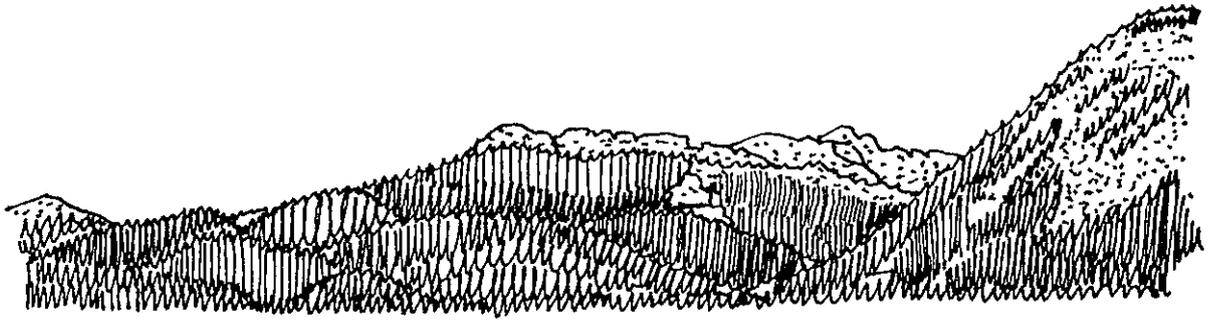

Roads can create scars on the landscape. The more miles of roads built to accommodate timber management activities, the more severe is the visual alteration to the landscape. Roads create horizontal form, line and color contrast usually associated with timber harvest areas and the adjacent landscape. Also associated with roads are gravel borrow sources. Gravel sources also create form and color contrast upon the landscape by removing the material permanently from its natural setting.

Prescribed fire following timber harvest blackens earth and woody debris left on the ground, and scorches trees and needles. Fire results in stark color contrasts of brownish black against the green textured, forested surroundings. Shaded fuel breaks produce a linear, open to broken, canopied effect on the landscape as compared to a naturally textured landscape.

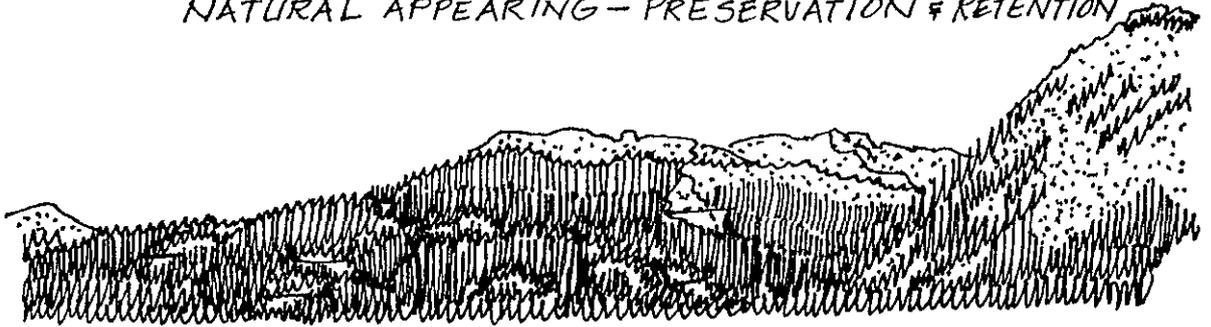

The amenity-oriented alternatives will have a greater number of acres allocated to prescriptions with a visual quality objective of Preservation, Retention or Partial Retention. These would provide for higher scenic quality and a more natural-appearing landscape (see Figure IV-2). Conversely, the commodity-oriented alternatives have higher levels of timber harvest and allocate more acres to Modification and Maximum Modification visual quality objectives, resulting in a more pronounced alteration of the landscape and a greater visual impact (see Figure IV-2).

Tables IV-5 and IV-6 describe the visual condition of the viewsheds and major lakes on the Forest by area and by alternative.

Kachess Lake

All alternatives except the NC alternative would treat the lakes and surrounding landscape in a high visual quality

The number of acres allocated to General Forest and the number of viewsheds allocated to prescriptions resulting in a natural-appearing or slightly altered condition, indicates the likelihood of effects to scenic values, by alternative.

Alternative E allocates approximately 154,000 acres to General Forest and retains 33 of 34 viewsheds in scenic management.

Alternative F allocates approximately 202,000 acres to General Forest and retains 32 of 34 viewsheds in scenic management.

Alternative G allocates approximately 224,000 acres to General Forest and retains 32 of 34 viewsheds in scenic management.

Alternatives A/NFMA and H allocate approximately 393,000 acres to General Forest and retain 33 of 34 viewsheds in scenic management, but 18 of the viewsheds will be in a slightly altered condition.

Alternatives C and I allocate approximately 389,000 acres to General Forest and retain 27 of 34 viewsheds in scenic management.

Alternatives B and D allocate approximately 613,000 acres to General Forest and retain 2 of 34 viewsheds in scenic management.

Alternative J allocates approximately 615,000 acres to General Forest and retains no viewsheds in scenic management.

Alternative NC allocates approximately 1,000,000 acres to General Forest and retains 1 of 34 viewsheds in scenic management

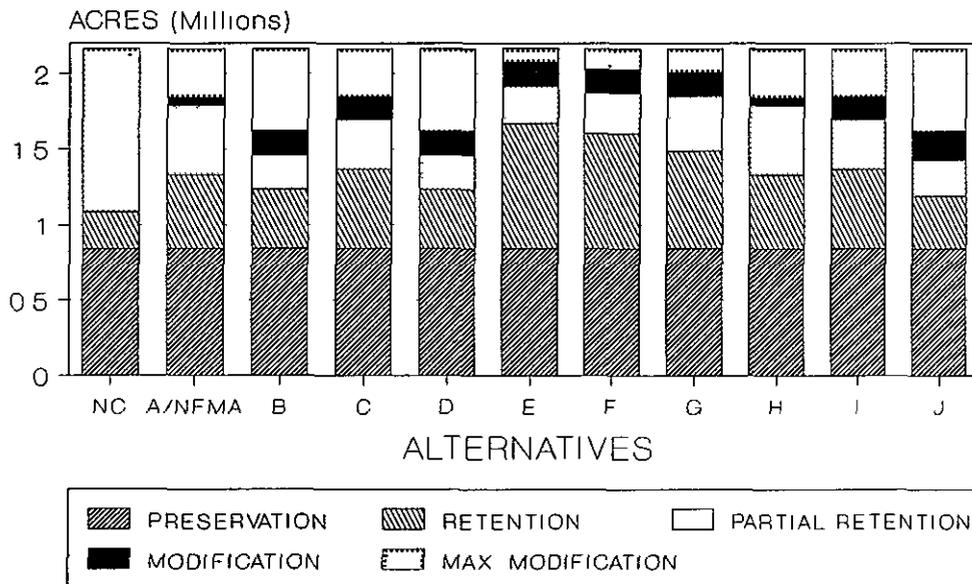

In summary, the ranking by alternatives based upon the acres allocated to General Forest and viewsheds managed for scenic management from highest (greatest protection for scenic values) to lowest are E, F, G, A/NFMA and H, C and I, B and D, J and NC (see Figure IV-4).

3) Effects of Range Management on Scenery

The management of forage for livestock range creates textural and color contrast from a natural-appearing grasslands to one that may be depleted of grasses, brown in color and may present a trampled-appearing, open space landscape. Valley bottom landscapes are very vulnerable to potentially heavy use by livestock. The amount of grazing, time of year, frequency of use and the management of the allotments can determine the degree of visual alteration of the land.

Alternatives E, F and G have approximately 7,000 acres allocated to Modification, C and I have approximately 18,000 acres, Alternatives A/NFMA and H have 34,000 acres, J has 62,000 and B and D have 82,000 acres in Modification.

**FIGURE IV-4
VISUAL QUALITY OBJECTIVES BY ALTERNATIVE**

b. Cumulative Effects of Each Alternative

The rate, distribution, scale, and type of timber harvest methods will determine the cumulative effects upon a natural-appearing, forested landscape. Form changes occur when clearcutting is done. When an area or viewshed is rapidly being cut the cumulative visual effects will be the greatest. How the timber management activities are distributed on the landscape in relationship to the viewer causes perception of a natural-appearing to heavily altered landscape. The closer the management activity to the viewer, the more apparent the visual perception. The scale of vegetative management activities creates visual impacts. When the units appear as openings, the activity is more visible.

The discussion and prediction of visual condition refers only to the National Forest land within the viewsheds. In reality, the viewsheds along some of the Forest's sensitive viewing locations are a mixture of ownerships. Timber management activities on private land seldom meet the visual quality objectives recommended by the visual management system. There will likely be heavily altered areas within viewsheds where the Forest is trying to achieve a more natural appearance. Where this occurs, the cumulative effect on the visual condition of the viewshed as a whole will be to create a more heavily altered appearance than predicted in Tables IV-5 and 6. Careful design and scheduling of harvest units can mitigate the effect of cutting on private land by eliminating straight lines and square corners, thus creating a cumulative effect which is less detrimental than the effect of private land activities alone.

The alternatives that have the highest number of viewsheds in a natural-appearing and slightly altered landscape will have the highest degree of scenic protection against cumulative effects. These viewsheds can be altered to heavily altered by increased yearly entries for vegetative manipulation.

Alternatives with the highest level of visual quality prescriptions and the lowest level of vegetative manipulation will have the best chance of maintaining scenic quality.

Alternatives E, F, and G offer the greatest protection to the viewsheds, with A/NFMA, C and I having reduced scenic protection, and NC, B, D, and J having the lowest protection from cumulative effects. In every alternative the potential for cumulative effects are present. However, NC, B, D, and J will alter, to heavily alter the landscape through modification of the viewsheds and through allocation of a large number of acres to timber, range and wildlife management prescriptions.

c. Alternatives' Conflicts With Other Agency Plans and Policies

A conflict between the effects of the alternatives and other plans and policies is the Washington State Scenic Travel route designation on White Pass Highway 12. In Alternatives B, J and NC, the highway will not be managed to compliment the Washington State Scenic Travel designation.

The Alpine Lakes Management Plan provides direction for the management of the visual resource in a high quality manner, except in the NC Alternative.

The Mather Memorial Parkway (Highway 410) has been designated as a scenic resource, with primary emphasis on use of the area for recreation purposes in all but Alternative J.

Management of the Pacific Crest National Scenic Trail that crosses the Forest emphasizes the retention of high levels of visual quality, except where intermingled ownership is present.

The Chelan County Land Use Plan designates the Icicle drainage as a Design Review Overlay District. This district is intended to provide for design and environmental review in conjunction with the standards and requirements of the underlying zoning. The goal within the Icicle Valley is to "encourage retention of the scenic character and environmental quality of the Icicle Valley". The Forest Service management of the Icicle is compatible with the Design Review Overlay District in all alternatives except NC.

Areas of non-federal “checkerboard” lands throughout the Forest have different land management policies. Even with coordination with these owners in the checkerboard areas, it is difficult to maintain scenic quality. The historic trend of heavily altered vegetation is likely to continue.

d. Mitigation Measures for Scenery

Mitigation measure for scenery are found in several published visual resource handbook guides. These guides are kept in the National, Regional, Supervisor’s, and District offices of the U.S. Forest Service. The Standards and Guidelines in the Plan will provide data to reduce the negative effects upon the landscape. The amount of vegetation management will be kept in small scale units, and disturbances will be kept to a minimum in the scenic and special areas.

In scenic viewsheds, timber harvest areas will be shaped to blend with the terrain and to minimize contrast with the character of the existing landscape. Uneven age or partial cutting techniques will be utilized more than contrasting form (clearcut) type units. Along critical roads, trails, streams, lakes and dispersed sites, timber harvest units may be restricted in size. Roads will be designed to a minimum standard or will be screened by vegetation, and will be seeded along steep cutbanks.

Screening units with vegetation, designing smaller scale units, limiting the size, distribution and intensity of the management activities, using sophisticated logging systems (such as helicopter logging versus skyline), screening roads or limiting the number of visible roads in timber harvest units are ways to provide adequate mitigation of timber harvest and road construction activities.

Recreational settings are managed with visual objectives that reflect the concerns of recreational users and expected levels of recreation use. Developed sites have the potential to contrast dramatically with their surroundings; these potential contrasts are partially mitigated through the use of professional site planning and landscape design as well as through the use of native or natural-appearing materials and use of “earth

tone colors” for paints and stains. Use of an architectural style that blends with the landscape character and use of non-reflective material, vegetative screens, and dispersed or buried facilities may also mitigate the effects of recreation site development.

The mitigation measures require planning and design, using an interdisciplinary approach with an emphasis on the design arts. Their level of effectiveness is determined by the land allocation within the particular landscape character type. Activities on steep, highly visible landscapes with open to broken canopies are less easily mitigated than those on flatter and even-textured landscapes. In addition, the economic factor in meeting the cost of logging with sophisticated systems will make these measures the most difficult to accomplish.

Mitigation measures for protecting scenery would be more effective in those alternatives that provide an emphasis on high scenic values, and that have a greater number of acres allocated to Preservation, Retention and Partial Retention visual quality objectives. These would be harder to achieve in those alternatives with a high level of intensive management allocations, such as in Alternatives NC, B, D and J.

When visual resource mitigation measures are used, the end result usually will be a pleasing, natural looking landscape. Structures will blend better with the scenery. The Highway 12, White Pass viewshed is an example of the application of visual resource management principles for the past 15 years

6. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON WILDERNESS

The Wenatchee National Forest has a portion of seven designated wilderness areas that comprise the main backbone and high ridge systems of the Cascade Mountain Range. Management of these wilderness areas is shared with adjoining National Forests. The total area on this Forest is 841,034 acres. A thorough description of each wilderness is located in Chapter III of the FEIS.

Wilderness is generally considered to have physical, biological, and social resource values. The physical and biological resources are intended by the Wilderness Act to exist in a natural state, unimpaired by the actions of people and free to change under natural actions. Social resource values are intended to allow recreation visitors freedom, a feeling of solitude and the opportunity to face the challenge of a natural environment. These resource values are subject to change or negative impact by the management of the National Forest and the actions of recreation visitors in wilderness.

The acres of designated wilderness do not change by alternative and no new acres of wilderness are recommended in the final Forest Plan.

a. Direct and Indirect Effects of the Alternatives on Wilderness

The management of wilderness areas does not vary by alternative. However, the type and intensity of resource management adjacent to the wilderness, and the type and degree of access afforded does vary. This could cause a change in the Wilderness Recreation Opportunity Spectrum (WROS) classes within the wilderness where the boundary is shared with non-wilderness lands. This could affect both solitude and the overall quality of the recreation experience.

The higher the intensity of resource management activities which take place adjacent to the wilderness, and the greater the ease of access, the greater the effect upon the wilderness experience. These will also mean an increasing need for management controls within the wilderness in

order to maintain the social attributes needed to provide the experience level consistent with the WROS class.

The primary effects of activities adjacent to wilderness boundaries are as follows:

1. Road construction, timber harvest and other commodity management activities will be visible from areas inside wilderness, detracting from the quality of the experience.
2. Noise, dust and smoke will be audible or visible from areas inside wilderness, which will also detract from the quality of the wilderness experience.
3. New road construction will tend to increase access to wilderness or make access easier, resulting in an increase in visitors to certain areas. Increase in visitor use can be detrimental to wilderness resources in many locations.
4. New road construction and development activity may impact the view and recreation setting on trails leading into wilderness.
5. A decrease in unroaded areas adjacent to wilderness will likely tend to displace users seeking unroaded recreation, into wilderness. This may result in increased human impacts on wilderness resources.

Table IV-7, which follows, indicates the relationship of unroaded and roaded recreation setting allocations adjacent to each wilderness boundary for each alternative. It also indicates the approximate amount of the unroaded setting that is motorized and non-motorized.

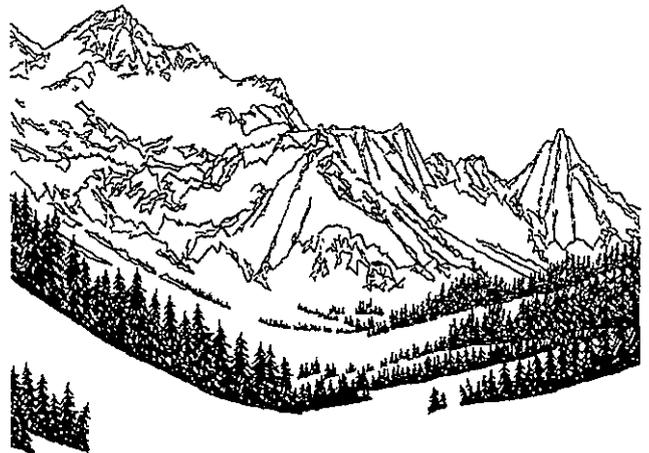

Table IV-7

Roaded	79	100	100	100	51	87	87	79	100	100

1/ As water is not "allocated," the boundaries adjacent to Lake Chelan are not included. Lake Chelan does have motorized boat traffic

2/ Figures are not available for Alternative NC.

In all but Alternatives E, F and G the allocation of unroaded areas adjacent to wilderness boundaries are very similar. The Henry M. Jackson Wilderness has 30% of the boundary unroaded in Alternatives C and I. Other than this, effects from management activities adjacent to wilderness boundaries will not vary a great deal.

There is a noticeable difference in Alternatives E, F and G due to the amenity and unroaded recreation emphasis of these alternatives. The effects of activities adjacent to wilderness boundaries will be less distinguishable. Alternative E will have the least effects of all the alternatives.

b. Cumulative Effects of Each Alternative

Since management of wilderness is constant in all alternatives, the potential for cumulative effects exists as a consequence of the effects of the alternatives on lands adjacent to wilderness boundaries. The greatest potential for any cumulative effects will result from alternatives that allocate the greatest number of acres adjacent to wilderness boundaries to intensive, roaded management.

There are three potential cumulative effects on wilderness from management of adjacent lands.

1. Impacts on visual qualities and the qualities of the wilderness experience resulting from successive episodes of road construction and timber harvest that are visible from wilderness.
2. The resource impacts resulting from increased visitor use, over time, that may be a result of improved access to specific locations and of users displaced into wilderness.
3. Effects of air quality and air quality-related values from a combination of activities outside wilderness.

Alternatives B, D, and J have the highest potential for these impacts to occur due to the number of acres of roaded allocations adjacent to wilderness, and due to the emphasis of these alternatives. Alternatives NC, A/NFMA, C, H and I also

have a high potential for these cumulative effects to occur, but somewhat less than Alternatives B, D and J.

Alternatives E, F and G have the least potential for the described cumulative effects to occur, with Alternative E being the very least.

c. Alternatives' Conflicts With Other Agency Plans and Policies

The Forest Service wilderness philosophy, which remains unchanged by each alternative, may conflict with policies of other agencies such as the U.S. Geological Survey for taking mineral samples, the Environmental Protection Agency for taking water samples, and the Soil Conservation Service for taking snow surveys. It may also conflict with the Washington State Department of Game fish stocking program.

d. Mitigation Measures for Wilderness

Mitigation measures for wilderness that would reduce or eliminate the effects of the alternatives are primarily oriented to how development occurs. Transportation planning before road systems are designed and located, can emphasize locating roads to minimize the visual impacts as viewed from wilderness. Timber sale planning can emphasize unit shaping to reduce visibility and contrast as seen from wilderness trails and commonly used areas. Management activities that produce noise, dust or smoke can be scheduled for periods of low visitor use early or late in the season. Roads can be closed to public travel to prevent the easy access to wilderness that might be provided by the road locations. Trailheads and trails can be relocated to reduce ease of access in some situations.

The effects of visitor use and management activities outside wilderness that impact wilderness resources, will be monitored. See Appendix E of the Forest Plan for a more detailed description of the management actions that may be implemented to reduce impacts on wilderness resources.

**7(A) ENVIRONMENTAL
CONSEQUENCES OF THE
ALTERNATIVES ON WILDLIFE
(MANAGEMENT INDICATOR SPECIES)**

The issues for wildlife are ensuring that populations of all species remain viable throughout their ranges, meeting the demand for recreation use of wildlife, and ensuring a diversity of animal communities across the Forest. The environmental consequences of the alternatives on wildlife are described in terms of the effects on management indicator species (MIS) and their habitats.

a. Direct and Indirect Effects of the Alternatives on Wildlife

Management indicator species represent an entire group of species that utilize similar habitats. Selected species include threatened and endangered species, species with special habitat needs that may be influenced significantly by management activities, species commonly hunted, fished, or trapped, and species whose population changes indicate effects of management activities on other species of a major biological community or on water quality (36 CFR 219.12) (See Chapter III of the FEIS for selection of the MIS).

In order to assess effects of the proposed alternatives, the following discussion is organized into habitat groups. The following species were selected to represent each habitat group:

<u>Habitat Groups</u>	<u>Species</u>
Big Game Habitat	Mule Deer, Rocky Mountain Elk, Mountain Goats
Primary Cavity Excavator Habitat	Downy Woodpecker, White headed Woodpecker, Hairy Woodpecker, etc
Mature and Old Growth Habitat	Spotted Owl, Pileated Woodpecker, Marten, Northern Three Toed Woodpecker
Riparian Habitat	Beaver, Ruffed Grouse

Management activities that have major effects on wildlife and wildlife habitat are timber, recreation, and range. The discussion for timber and recreation will include associated road management. This discussion of environmental consequences will involve a comparison of the alternatives to the first decade outputs of Alternative A/NFMA, current direction.

Big Game Habitat

Mule deer, Rocky Mountain elk, and mountain goats are the management indicator species for big game habitat. Mule deer are found throughout the Forest whereas elk are found primarily in the southern half of the Forest. Mountain goats are found in small populations throughout the Forest. Due to the complexity of habitat requirements and effects of management activities on these three species, and the general nature of the Forest FEIS, this discussion is limited to Forest-wide consequences. During the implementation of the Land and Resource Management Plan an analysis of site specific effects will be conducted for proposed management activities.

1) Effects of Recreation on Big Game

Recreation management activities that can affect big game and big game habitat include construction and use of developed sites and trails, use of dispersed camp sites, off highway vehicle use, and use of open road systems. These activities have an adverse effect by displacing animals at the site of recreation use and by making adjacent areas less desirable for animal use due to disturbance associated with movement and noise. Experience on the Forest indicates that the greatest impact of recreation on big game is use associated with open road systems. Alternatives with the most miles of open roads would have the most impact on big game.

All alternatives provide for recreation use that would reduce big game use in some areas. Alternatives with fewer unroaded, motorized recreation allocations (RE-2a and 2b), more road closures, and more unroaded, non-motorized allocations (RE-3) would have less impact on big game. These alternatives include C, E, F, and I. Alternatives NC, A/NFMA, B, D, G, H, and J would tend to have a greater impact on big game due to the nature of the recreation allocations.

2) Effects of Timber Management and Roads on Big Game

Activities associated with timber management that have a significant effect on big game and their habitat include road construction and use, even-age harvest methods, and reforestation. Road construction has the direct effect of eliminating habitat, and road use has an indirect effect of reducing big game use in adjacent areas. Even-age harvest methods (clearcut, select, and seed tree) alter habitat components by changing the distribution, amounts, and arrangement of cover and forage; such changes can be beneficial or detrimental depending on current habitat conditions. The intensity of reforestation of harvested units will also determine effects on big game habitat. *Intensive reforestation decreases the amount of time a unit will produce forage while increasing the restoration of hiding and thermal cover.* In areas where forage is limited, intensive reforestation can have an adverse effect on big game.

The general effect of timber management on big game for each alternative can be determined by the amount of land allocated to the General Forest (GF) prescription, which emphasizes timber production. The influence of timber management on forage/cover requirements and the impacts from associated road use may increase or decrease overall habitat effectiveness for big game. Alternatives A/NFMA, C, H, and I have similar GF allocations and would have moderate effects on big game summer range habitat conditions. Alternatives NC, B, D, and J have high allocations to GF with a correspondingly high potential for impacts; and Alternatives E, F, and G have low allocations to GF and therefore, low impacts to big game.

3) Effects of Range Management on Big Game

Range management activities that affect big game and their habitat include structural range improvements (water developments and fences), non-structural improvements (weed and brush control and forage enhancement), and forage utilization. Water developments and forage enhancement projects tend to have a positive effect on big game while fence construction tends to impede the movement of big game. Forage

utilization by livestock can have both a beneficial and adverse effect on the availability of forage for big game. Properly implemented, livestock grazing on select plant species can maintain desired forage conditions for big game.

All alternatives would continue to allow livestock grazing in designated grazing allotments. In most cases, within big game summer range there would be little or no effect of range management on big game habitat. An exception is the Colockum elk herd summer range where forage is a limiting factor.

All alternatives would allow grazing on big game winter ranges within grazing allotments. The effect of this grazing on big game winter range conditions would be dependent on the management objectives established in allotment grazing plans.

Alternatives with large allocations to the Intensive Range Management (RM-1) prescription, such as A/NFMA, B, D, and H, would have a greater effect on big game winter range than other alternatives with fewer acres allocated to that prescription. Alternative C would have little or no effect on both summer and winter range due to the goal of the range program to provide other resource outputs.

Management Areas EW-1 and EW-3 were developed to provide specific management strategies for the maintenance and/or improvement of key big game habitats on both summer and winter ranges. Alternatives with high allocations to these prescriptions would benefit big game more than those with little or no allocations. Alternatives C, E, F, G, I, and J would all have in excess of 100,000 acres allocated to EW-1 and/or EW-3. Alternative NC would have no allocation to these prescriptions and the other alternatives would have allocations of less than 78,000 acres.

Primary Cavity Excavator Habitat

The primary cavity excavator habitat is represented by species such as the downy woodpecker, white headed woodpecker, and hairy woodpecker. These species represent approximately 85 species of birds and mammals that require standing dead trees during all or a portion of their life cycle.

The unit of measure for this habitat component is referred to as the "percent snag level" - that is, the number of snags in each decay class, per a selected number of acres, which meet the minimum size requirements to maintain a specified percentage of the population of primary cavity excavators.

1) Effects of Timber Management on Primary Cavity Excavator Habitat

Management activities that have a significant impact on the snag habitat component include timber harvest and the associated road construction, and firewood cutting. Intensive timber management not only reduces the abundance of existing and future snags it also reduces the size class of snags in future stands. Short rotation management strategies would create smaller snags. Thomas (1979) lists 62 species that require snags for nesting; 58 of those species require snags with a diameter greater than 10 inches and 12 require snags greater than 20 inches in diameter. Road construction has the direct effect of eliminating snags and an indirect effect of increasing access for firewood cutters which also eliminate snags in areas where they are easy to reach.

All alternatives have standards for snag management that would meet or exceed that needed to maintain minimum viability levels. Alternative NC, while not including the requirements of NFMA, has Regional direction to maintain snag habitat at the 40 percent level.

The Forest-wide standard for primary cavity excavator habitat provides for an average snag level of 40 percent in a sub basin and no less than 20 percent within a forty acre unit. Land allocations that do not allow timber harvest would have snag levels at or near natural conditions. Land allocations that allow timber harvest but emphasize other resource objectives would have a snag level of 60 percent or more. While all alternatives would meet or exceed the viability requirements, those that have the lower allowable sale quantity levels would have the least impact on snag habitat. Alternatives E, F, and G would have the least impact on primary cavity excavator habitat, A/NFMA, C, D, H, and I would have a moderate impact, and NC, B, and J would have the most impact.

Mature and Old Growth Habitat

Management indicator species for mature and old growth habitats are northern spotted owl, pileated woodpecker, pine marten, and northern three-toed woodpecker. These species are used as a group to provide a measure of mature and old growth habitat for all species dependent upon late seral stage forest stands. An important relationship to keep in mind when evaluating the effects on the MIS is that while a spotted owl management area would provide habitat conditions for the pileated woodpecker and/or pine marten, the reverse is not true. Two habitat factors can limit the populations of species that depend on mature and old growth habitats - the amount of suitable habitat in a given area and the distribution between suitable habitat areas. For the more mobile species like the spotted owl the distance between areas can be 6 to 12 miles, however, for species that are less mobile (i.e. mice and voles) the distance needs to be shorter, such as that established for pine marten and northern three-toed woodpeckers.

1) Effects of Timber Management on Mature and Old Growth Habitat

Timber management has a significant impact on mature and old growth habitat, particularly through the use of Forest practices that require intensive management with a short rotation. This can eliminate mature and old growth habitat altogether. Those alternatives that have the most acres allocated to the GF prescription would have the greatest effect. Road construction also eliminates the old growth characteristics by removing trees that constitute mature or old

growth habitat. However, all alternatives except NC have provisions to meet or exceed the requirements for species viability.

Alternatives E, F, and G would provide the greatest amount of mature and old growth habitat and have the least number of acres allocated to the General Forest prescription, the effects of timber management on mature and old growth habitat would be small. Alternatives A/NFMA, B, C, D, H, I, and J would have a moderate effect on the distribution and abundance of mature and old growth habitats. Alternative NC would have the greatest effects on mature and old growth habitats; management under this alternative would threaten the viability of some species due to a decrease in the distribution and abundance of suitable habitats.

Riparian Habitat

The management indicator species for riparian habitats are beaver and ruffed grouse. These species represent an estimated 260 species that utilize riparian habitats, of which 24 are dependent upon riparian habitat for survival. Most of the riparian habitats on the Forest are linear in nature and found along streams and rivers; the remainder are found around lakes, reservoirs, and wet areas. Riparian habitats make up less than one percent of the Forest land base. Wildlife use of riparian ecosystems is much greater than that of adjacent areas. These habitats provide unique micro-climates which are created through increased humidity, increased air movement, higher rates of transpiration, and more shade. Riparian habitats provide travel corridors for a variety of species and also provide natural edge effects with upland plant communities.

Riparian habitats are affected by virtually all forest management activities. These areas have traditionally been the sites of road construction, mineral exploration, recreation use and development, livestock grazing, water diversions and hydro electric development, and timber harvest. The management activities that continue to have significant effects on riparian habitat and on the species that utilize them are timber, recreation, road construction, and range. Riparian habitats are affected by activities in adjacent up-slope areas as well as those in the riparian zone itself.

1) Effects of Recreation, Timber Management, Range Management and Road Construction on Riparian Habitat

Timber harvest in riparian zones can result in impacts such as removal of shade, soil compaction and displacement, and a change in plant species. These effects lead to changes in structural habitat diversity, micro-climates, travel routes, and in the animal species that utilize the riparian habitats. Recreational use in the riparian zones have little effect on the riparian habitats but can have an adverse effect on species of wildlife that prefer solitude. Developed recreation sites in and adjacent to riparian habitat have a direct effect of destroying productive habitat and an indirect effect of concentrating more people in the riparian zone. Road construction has a direct effect of eliminating habitat, use of roads has an indirect effect of reducing habitat values in adjacent areas for species that prefer solitude. Livestock grazing, when kept within proper utilization levels, can have minimal impact on riparian resources, however, over grazing can have an adverse effect on riparian habitat.

The Riparian-Aquatic Habitat Protection Zone (EW-2) prescription was developed by the Forest to ensure that riparian dependent resources would be adequately protected in each alternative except NC. Alternative NC would follow current direction to give preferential consideration to riparian-dependent resources where resource management conflicts arise. This direction is not as protective of the riparian dependent resources as the direction provided in the EW-2 prescription. Alternatives A/NFMA, B, C, D, E, F, G, H, I, and J would either protect the riparian habitats under the EW-2 allocation or through other, even more restrictive allocations. However, Alternative C specifies more road closures than the other alternatives and, therefore, would have less of an impact on the riparian habitats.

b. Cumulative Effects of Each Alternative

Big Game Habitat

The cumulative effects of the alternatives on big game include a combination of the effects of the above mentioned management activities and land allocations with the effects of other factors such as wildfires and the activities of other landowners.

The impact of wildfires on big game habitat can be dramatic due to the ability of a fire to alter large areas of habitat in a relatively short time period. Where important cover is lost, the effects can be long lasting. The loss of forage and browse, while a short term effect, can have an impact on wintering herds on key winter range for the first few years following the fire. The Forest has a long history of large fires which have had impacts on big game populations, however, due to the unpredictability of the occurrence of large wildfires an assessment of future effects cannot be made. This point is raised here to remind the reader that wildfires do play an important role in the production of big game populations on the Forest.

The effects of other landowners on big game comes primarily from impacts to big game winter range. Approximately 60 percent of the big game animals that summer on the Forest, winter off the Forest. Winter range that is in other public ownership is either managed as winter range or has a management strategy that does not adversely impact the winter range values. However, those winter range areas that are in private ownership are being altered to a point where the winter range values are being lost. Agricultural, commercial, and residential development have all had an impact on traditional wintering areas; this loss of winter range places more importance on the management of winter range on the National Forest. Alternatives that place more emphasis on winter range values would help mitigate the loss of winter range habitats on private lands.

The cumulative effects on big game cannot be determined only by comparing the number of acres allocated to the various prescriptions in each alternative. The relationships of the allocations can be more important than the amount. The discussion and display below reveal the consequences of the proposed alternatives on big game. These consequences are a result of the direct, indirect, and cumulative effects.

Alternative A/NFMA would result in no significant change in big game populations for the first decade. When compared to Alternative A/NFMA the other alternatives would result in the following variations in big game numbers during the first decade (the numbers in Table IV-8 are to facilitate comparison between alternatives only, and are not intended to be used as precise counts).

TABLE IV-8
CHANGES IN BIG GAME POPULATIONS BY ALTERNATIVE

Alternative	Deer	Percent Change	Elk	Percent Change	Mountain Goat
A/NFMA	25,200* 9,700**	0 0	12,500* 5,400**	0 0	1,600
NC	23,200 9,600	-8 -1	11,400 5,400	-9 0	1,600
B	24,100 9,900	-4 +2	12,000 5,600	-4 +4	1,600
C	25,100 10,100	0 +4	12,500 5,600	0 +4	1,600
D	24,100 9,900	-4 +2	12,000 5,600	-4 +4	1,600
E	26,000 10,200	+3 +5	12,900 5,700	+3 +6	1,600
F	25,800 10,200	+2 +5	12,800 5,700	+2 +6	1,600
G	25,800 10,200	+2 +5	12,800 5,700	+2 +6	1,600
H	25,200 9,700	0 0	12,800 5,400	0 0	1,600
I	24,300 10,100	-4 +4	12,100 5,600	-3 +4	1,600
J	24,200 10,000	-4 +3	12,000 5,600	-4 +4	1,600

* Summer range

** Winter range

The long term trend in big game numbers that would result from implementing each of the alternatives can be determined from the data in Table II-3a in Chapter II. Alternatives NC, B, D, I, and J would result in a significant decrease (greater than 20 percent) in big game numbers by the fifth decade. The decreases would be the results of diminished habitat conditions on summer and/or winter ranges. Alternatives A/NFMA and H would both result in a 14 percent decrease in big game numbers. Alternatives E, F, and G would result in an 11 to 13 percent increase in big game numbers. Alternative C is the only alternative that would have no significant long term effect on big game numbers.

Primary Cavity Excavators

The cumulative effects on primary cavity excavator habitat can only be meaningful if determined on a subbasin level, with an analysis of the distribution, abundance, and size of the snags for the indicator species included. In general, the effects of activities on private land have little impact on the habitat of primary cavity excavators on the Forest due to the distribution requirements of the indicator species. As with big game, wildfires can have a pronounced effect on snag habitat - first by creating large acreages of snags in a short time period and second by eliminating trees that would provide future snags.

Mature and Old Growth Habitats

The cumulative effects on species that depend on mature and old growth habitats can be determined by analyzing those management activities that have an effect on the habitats. Of the various management activities on the Forest, timber management is the most likely to impact the late seral stage habitats. Wildfires can also eliminate large acreages of suitable mature and old growth habitat; an example would be the eastern portions of the Chelan and Entiat Ranger Districts that were exposed to several large wildfires over the past 20 years. Forest management practices on adjacent lands (other public and private ownerships) have had an effect on the distribution of suitable habitats off the Forest. In most cases the lands outside of the National Forest are not managed to maintain viable populations of species that depend on mature and old growth

habitats. Some suitable habitats outside the Forest are protected in Congressionally-designated areas such as National Parks and Recreation Areas.

The populations of species dependent upon mature and old growth habitat will decrease in all alternatives. The outputs predicted for mature and old growth habitat consider the direct and indirect effects of proposed management activities and to a minor extent the effects of impacts from other ownerships. The trends for Table IV-9 are the result of the predictions made in Table II-3a.

TABLE IV-9
TRENDS OF POPULATIONS
OF INDICATOR SPECIES FOR MATURE AND
OLD GROWTH HABITAT

Alternatives	Percent Change
NC	decrease 45%
B	decrease 25%
D	decrease 25%
J	decrease 25%
A/NFMA	decrease 25%
C	decrease 25%
H	decrease 25%
I	decrease 25%
G	decrease 20-25%
F	decrease 20%
E	decrease 20%

Riparian Habitat

The cumulative effects on riparian habitats are a result of a combination of the direct and indirect effects discussed above with the effects of wildfires and to some extent effects from other landowners. Wildfires impact riparian habitat by significantly altering the plant community structure and plant composition in and adjacent to the riparian zone. In most cases the ground cover and understory vegetation recover within a few years of a fire. However, the recovery of overstory trees that provide shade as well as nesting sites

takes much longer. Management activities on adjacent lands have little effect on the riparian habitats on the Forest.

c. Alternatives' Conflicts With Other Agency Plans and Policies

The Washington State Department of Wildlife has developed a plan for managing Washington's wildlife through the year 1995. This Plan, titled "Strategies for Washington's Wildlife, 1982 to 1995", identified state-wide goals for wildlife population levels. The State plan directs each Department of Wildlife region to develop a more specific plan for wildlife found within that region.

The Wenatchee National Forest lies within Department of Wildlife Region III, which has a completed plan for managing wildlife. The management goals of the Washington Department of Wildlife are:

- a. To increase elk populations by 10% on public lands. Only Alternative E, which has the highest number of elk, meets this goal for both summer and winter range. Alternatives F and G meet this increase in winter range only.
- b. To maintain mule deer at the ten year average population level for the period between 1970 and 1979. The Forest would meet this goal by maintaining or increasing deer numbers in both summer and winter range in Alternatives E, F and G.
- c. To maintain huntable population levels of mountain goats. The proposed management direction would maintain or increase mountain goat habitat in all alternatives.
- d. To increase bighorn sheep populations in three areas adjacent to the Forest. Presently two of those areas have established populations and the third area has a growing population. The Intensive Range Management (RM 1) allocations in Alternatives B and D could adversely affect this goal.
- e. To increase populations of ruffed grouse. This goal would be met in Alternatives A/NFMA, C, E, F, G, H, and I.

The Yakima and Colville Indian Tribes have the right to harvest deer and elk on the Forest. Even though neither of the Tribes have identified a specific number of animals for subsistence, both desire to maintain or increase the big game populations on the Forest. Alternatives E, F and G would best meet this need.

d. Mitigation Measures For Wildlife

The degree to which direct, indirect and cumulative effects are realized is a function of many variables, including the magnitude of proposed management activities, and the level of success in project design and implementation. A critical step in the process is the identification and successful application of mitigation measures. Mitigation measures are defined as actions to avoid, minimize, reduce, eliminate, or rectify adverse impacts of management practices. Mitigation measures for wildlife are designed to 1) ensure viability of all species, 2) recover listed species, and 3) maintain or improve habitat conditions for management indicator species.

The Forest is providing for mitigation of potential effects to wildlife in two ways. First is the development of management area prescriptions that emphasize wildlife habitat objectives. These management areas are Key Deer and Elk Habitat (EW-1), Riparian-Aquatic Habitat Protection Zone (EW-2), Key Big Game Habitat/Unroaded (EW-3), Old Growth Management (OG-1), Mature Habitat (OG-2), and Research Natural Areas (RN-1). The second method of providing mitigation is through the establishment of Forest-wide standards and guidelines as well as specific standards in each of the other management area prescriptions.

The mitigation measures listed below are common to all alternatives except NC. For more specific details see Chapter IV of the Forest Plan.

- a) Areas allocated to the Old Growth and Mature Habitat Management prescriptions are designed to provide a viable network and distribution of habitat for spotted owls, pine marten, northern three-toed woodpecker, and pileated woodpecker.

b) Forest-wide standards and guidelines have been established to maintain habitat around active nest sites of spotted owls outside the established spotted owl habitat areas. As these non-network areas are abandoned they could become available for timber harvest.

c) Range management in all alternatives is designed to maintain or increase outputs for other resource components except in the Intensive Range Management prescription (RM-1). Deer and elk forage would increase from this direction on both summer and winter ranges.

d) Mitigation for primary cavity excavator habitat varies by prescription and alternative. All alternatives would maintain viable populations of primary cavity excavators.

e) The effects of human activities on deer and elk populations in summer and winter range would be partially mitigated by closing most of the new roads built to harvest timber. See the Forest-wide standards and guidelines for road management in the Chapter IV of the Forest Plan.

7(B) ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON PROPOSED, ENDANGERED, THREATENED, AND SENSITIVE SPECIES

The issues for proposed, endangered, threatened, and sensitive species are the recovery of Federally listed species and the assurance that sensitive species will not become listed. All of the species in these categories are of concern to the Forest.

In order to assess the effects of the proposed alternatives, the following discussion is organized into groups of species that have similar management requirements.

a. Direct and Indirect Effects of the Alternatives on Proposed, Endangered, Threatened and Sensitive Species

Species With Recovery Goals

The Pacific Bald Eagle Recovery Plan established a recovery objective of 20 breeding pairs for Recovery Zone 6 (Cascade Mountains), which includes the Wenatchee National Forest. The Forest portion of this objective is eight breeding pairs.

All alternatives would meet the bald eagle recovery objective of eight breeding pairs, and would provide for the number of roosting, perching and wintering sites needed to meet bald eagle recovery objectives. Timber harvest and human activity near bald eagle nest and roost sites can have an adverse effect through alteration of the habitat and disturbance of the birds, particularly during the nesting season. Potential bald eagle habitats outside of that needed for recovery could be adversely impacted in areas allocated to the GF prescription. Alternatives NC, B, D, and J would have the highest amount of land allocated to GF, therefore, would have the highest potential of affecting those habitats. Alternatives A/NFMA, C, H, and I would have a moderate impact on these habitats due to a lower level of GF allocations. Alternatives E, F, and G would have the lowest amounts of GF allocation and, therefore, the lowest impacts to habitats.

<u>Management Groups</u>	<u>Species</u>
Species with recovery goals	Bald eagle and peregrine falcon
Species without recovery goals	Grizzly bear and gray wolf
Species proposed for listing	Northern spotted owl
Forest Service sensitive species	Bighorn sheep, Townsend's big-eared bat, Canadian lynx, California wolverine, ferruginous hawk, Swainson's hawk, and long-billed curlew.

Recreation management activities that can affect bald eagle habitat include construction and use of developed sites, use of dispersed campsites, and use of open road systems. These activities have an impact through disturbance of the bald eagles at the site of recreation use, through reduction of the areas available for feeding and use as preferred perch sites, and by providing access to bald eagle nesting areas. All alternatives provide for recreation use that could affect the bald eagle populations in some areas. Alternatives with fewer unroaded, motorized recreation allocations (RE-2a and 2b), more road closures, more unroaded, non-motorized allocations (RE-3), and less intensive levels of developed recreation would have a correspondingly smaller impact on bald eagles. These alternatives include C, E, F and I. Alternatives NC, A/NFMA, B, D, G, H and J would tend to have a higher likelihood of affecting bald eagles and bald eagle habitat due to the nature of the recreation allocations in these alternatives.

The Pacific Coast Recovery Plan for the American Peregrine Falcon has established a recovery objective of 30 breeding pairs for Washington state. A specific goal for the Forest has not been set.

All alternatives would contribute to the recovery of the peregrine falcon by protecting nests sites as they are located and through identification of potential sites for future introductions of the bird. Due to the location of peregrine falcon nest sites on cliffs and rock outcrops, timber management practices tend to have little effect on the falcon unless activities occur during the breeding and nesting period. The protection standards in all alternatives include operational limits during the breeding and nesting season. In effect there is no difference between the alternatives in the impacts that timber management would have on peregrine falcons.

The effects of recreation on the peregrine falcon, and their variation by alternative, would be similar to those identified for the bald eagle.

Species Without Recovery Goals

The grizzly bear and gray wolf are threatened species that were once found on the Forest. At the present time there are no established recovery goals for either of these species on the Forest.

Management activities that have the potential to affect gray wolves and grizzly bears and their habitats are road construction which increases access into former isolated habitats; livestock grazing which can lead to conflicts with these large predators; recreation use that tends to displace these animals but that can also lead to confrontations; and timber harvest that can change habitats and thus the food sources for the animals. Both of these species prefer and do well in large undisturbed areas where there is little or no contact with humans.

Alternatives that provide the most acres of the unroaded, non-motorized allocation (RE-3) and the fewest acres of GF would have the lowest impacts on the gray wolf and grizzly bear. Because of this, Alternatives E, F, and G would have the lowest impact on these species and their habitats. Alternatives A/NFMA, C, H, and I would have a moderate impact and Alternatives NC, B, D, and J would have the highest impact.

Species Proposed for Listing

The northern spotted owl is the only species in this category. The Forest provides suitable habitat in all alternatives but NC to meet the standards and guidelines of the Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide. The US Fish and Wildlife Service is currently drafting new standards for the management of spotted owl habitat. When those standards are final the Forest will make the appropriate adjustments to implement them. For a discussion of effects of the proposed alternatives on spotted owl see the Wildlife Section, Mature and Old Growth Habitats. Also refer to the Northern Spotted Owl discussion in Appendix I of the FEIS.

Forest Service Sensitive Species

The sensitive species on the Forest are bighorn sheep, Townsend's big-eared bat, Canadian lynx, California wolverine, ferruginous hawk, Swainson's hawk, and long-billed curlew. There are no inventories for these species and the direction for management is general. Through the NEPA process all projects will involve site specific habitat inventories and biological evaluations to assess the potential effects of proposed activities on sensitive species. Species management plans will be developed for each sensitive species.

With respect to the wolverine, the combination of the WI-1 (wilderness) and RE-3 (unroaded, nonmotorized) land allocations will maintain sufficient habitat to ensure viable population levels. Alternatives E and F, with the largest number of acres allocated to these prescriptions, would provide the greatest protection, followed by Alternatives C, I and G. Alternatives B and D, with fewer acres in these prescriptions, would provide less protection for the potential habitat, with Alternatives NC, A/NFMA and H offering the least.

Due to the lack of data for the other species on the Forest and a lack of scientific information on the relationship of Forest management activities to these species, a determination of the potential effects of the alternatives cannot be made at this time. However, the lack of this information is not essential to a reasoned choice among the alternatives. In addition, with the application of mitigation measures contained in the Management Prescriptions combined with the strategy for collecting this information that is outlined in the Forest-wide Standards and Guidelines for Endangered, Threatened or Sensitive Species (see Chapter IV of the Plan), no foreseeable significant impacts to these species should occur.

b. Cumulative Effects of Each Alternative

With the exception of the northern spotted owl, there is a lack of specific information for the proposed, endangered, threatened and sensitive species and their habitats. As a consequence, a cumulative effects assessment cannot be made at this time. However, as noted above, this lack of

information is not essential to a reasoned choice among the alternatives. For a discussion on the northern spotted owl refer to the Wildlife Section, Mature and Old Growth Habitats and Appendix I.

c. Alternatives' Conflicts with Other Agency Plans and Policies

The U.S. Fish and Wildlife Service and the Washington State Department of Wildlife are responsible for establishing standards to ensure the viability of wildlife populations. The U.S. Fish and Wildlife Service has developed recovery plans for the bald eagle and the peregrine falcon. After consultation with this agency, the Forest has incorporated modifications that would ensure conformance with the recovery objectives of those plans in every alternative.

d. Mitigation Measures For Proposed , Endangered ,Threatened, and Sensitive Species

Specific mitigation measures common to all alternatives that would ensure the recovery and protection of the proposed, threatened, endangered and sensitive species on the Forest include:

- a) Implementation of Forest-wide Standards and Guidelines which state the direction necessary to provide habitat for these species. The development of a Species Management Guide for each sensitive species will provide more detailed information on habitat needs.
- b) Maintaining snag standards that meet or exceed the management requirement level of 20 percent.
- c) Constraining the timing of activities near nest sites of birds of prey to avoid disturbance during the nesting season (FSM 2405.14, R-6 Supp. 319).
- d) Authorization of road closures to improve habitat effectiveness for big game, to reduce impacts to snags, and to reduce human disturbances near nest sites
- e) Establishment of potential bald eagle nesting areas to meet recovery objectives,

For a more detailed description of standards and guidelines that address threatened, endangered and sensitive species, see Chapter IV of the Forest Plan.

8. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON FISHERIES

The Wenatchee National Forest manages fish habitat for commercially and recreationally valuable species including spring and summer chinook salmon, sockeye salmon, summer steelhead trout and several resident trout species. The fish habitat management objective for the Wenatchee National Forest is to at least maintain current habitat conditions, and show improving trends in habitat capability overtime. The success at meeting fish habitat objectives is dependent upon maintaining water quality, maintaining or improving access to available habitat; and providing for instream cover, pool quality, stream channel stability and high quality spawning habitat.

Anadromous fish runs to streams within the Wenatchee National Forest are depressed compared to historic levels and many streams are considered to be underseeded. Depletion of the runs has occurred due to many factors outside the influence of the Forest, including losses at main-stream Columbia River dams, water diversions downstream of the National Forest and overharvest.

Loss of habitat within the Forest due to past land management activities, such as logging and roading, has probably also contributed to the loss of fish production. While much of the reduction in anadromous fish produced within the Forest has occurred downstream, and much of the future production of anadromous fish will depend upon the success of downstream improvement projects, such as those currently being implemented through the Northwest Power Planning Council's Columbia River Fish and Wildlife Program, management of anadromous fish habitat within the Forest will be an important factor in meeting production objectives in the Yakima, Wenatchee and Entiat Sub-basins.

Fish habitat capability and production are expected to increase under all alternatives except NC through the life of the Plan. Long-term fish habitat capability may decrease under Alternative NC. Fish outputs displayed in the document are estimates and actual outputs will depend upon the success of a variety of programs both on and off the Forest. Fish habitat capability is also an estimate and will need to be better quantified through implementation of the Forest Plan, including the stream survey program and the monitoring program. For a relative comparison of the outputs and trends expected by alternative, the reader is referred to Table II-3b in Chapter II of this document. Improvements in habitat capability are expected to occur due to habitat improvement projects, implementation of Best Management Practices (BMP's), and Forest Plan Standards and Guidelines. How successful these improvements will be at meeting fish habitat objectives also will be monitored and adjustments made as new information becomes available. This chapter will include a discussion of the relative risks associated with alternatives at meeting fish habitat objectives.

The demand for fish is high and expected to increase over time. Anadromous fish runs in the Columbia River have been estimated to have been five times greater than present. Fisheries are currently restricted due to the excess demand. Fishing for resident trout is also very popular and interest in sport fishing is expected to increase substantially in Washington over the next 50 years. Due to the high demand for fish, the maintenance and rehabilitation of fish habitat is of great concern to the public, the Indian Tribes and Federal, State and local agencies.

a. Direct and Indirect Effects of Each Alternative on Fisheries

Management of fish habitat interacts with nearly all resource management activities on the Wenatchee National Forest. Nearly all management activities can also produce potential effects on fish and fish habitat. Land management activities felt to have the highest probability of affecting fish habitat capability are timber harvest, roading, mineral activity, grazing, recreation, Wild and Scenic River status and fish habitat improvement projects.

1) Effects of Recreation on Fisheries

Sport fishing for anadromous and resident fish produced on the Wenatchee National Forest is a popular recreational activity. While improvements in fish habitat may result in more fishing opportunities, recreational use of the Forest can negatively impact the fish resources. Development of roads increases the access to fish resources which can result in increased fishing opportunity and over-exploitation of wild stocks if not administratively controlled. Both dispersed and developed recreation can increase trampling of riparian vegetation, compaction of riparian soils and sedimentation from trails.

Forest-wide Riparian Standards and Guidelines are designed to reduce adverse impacts to fish habitat and allow natural stream processes important for maintaining fish habitat to function. However, as more land is allocated to developed and roaded recreation, the risk of impacts increases.

Semi-primitive recreation allocations protect fish habitat from most forms of man-caused impacts except those related to motorized use, helicopter logging, mining or similar activities.

Alternatives with the most acres in non-motorized, semi-primitive allocations such as Alternative E (320,038 acres) and F (259,088 acres) would provide the most protection and have the least potential for impacts to fish habitat from recreation. Alternatives C and I (116,092 acres) and G (100,362 acres) would have somewhat greater risk of damage to fish resources than Alternatives E and F, while alternatives with the least land allocated to semi-primitive unroaded allocation, Alternatives B, D, J, H, A/NFMA and NC would have the greatest potential risk of adverse fish habitat impacts. Alternative NC would pose the greatest risk because Forest-wide riparian standards would not apply.

2) Effect of Wild and Scenic River Recommendations on Fisheries

Wild and Scenic River recommendations increase the likelihood that natural functions of fish habitat are protected during future planning. Wild River status would allow the least develop-

ment in stream corridors and thus provide the most protection to natural stream processes. A Scenic River designation provides somewhat less protection than a Wild River, while Recreational River classification allows the most development and thus relatively less protection than either Wild or Scenic designation.

Wild and Scenic River designation would provide the most protection to fish habitat under Alternatives C, E, F, H and I as these alternatives propose the greatest number of rivers for Wild, Scenic and Recreational River management as well as have the most acreage managed as Wild River. Alternatives A/NFMA and G recommend fewer river miles for Wild, Scenic and Recreational River management. This would provide somewhat less opportunity for protection of natural stream processes. Alternatives B, D, J and NC would provide no additional protection to any streams as there are no rivers proposed for designation.

3) Effects of Fish Habitat Improvement Projects on Fisheries

Fish habitat improvement projects are designed to rehabilitate fish habitat degraded by past man-related activities or in some cases natural events or conditions. Projects could include correcting passage at culverts or falls blocking access to usable habitat, addition of large wood or rock structures to improve instream habitat, or projects to reduce sediment input. These projects are most beneficial when they are used to rehabilitate current conditions and not to mitigate the effects of further resource development. Although the intent is to improve or restore stream channel and riparian habitat conditions, damage could result or full potential benefits not be realized. This could be due to administrative error, poorly planned and/or implemented projects, or excessive reliance on improvement projects to mitigate effects of resource developments

It is the objective of all alternatives to maintain fish habitat at existing levels and use habitat improvement projects to rehabilitate conditions created by past land management activities. For this discussion, habitat improvement funds are assumed to be generated from two sources, appropriated monies (P&M) or Knutson-Vandenberg (KV) funds. Alternatives with greater

timber harvest and resource development carry relatively more risk, as discussed in the timber harvest effects, so greater habitat improvement funds will be needed to mitigate effects of resource development.

**TABLE IV-10
HABITAT IMPROVEMENT FUNDS BY ALTERNATIVES AND FUNDING SOURCE**

	A/NFMA	B	C	D	E	F	G	H	I	J	NC
P&M	36,945	17,000	188,840	0	680,000	340,000	17,000	6,800	85,000	45,000	36,945
KV	24,630	418,200	246,300	295,800	166,600	197,000	244,800	244,800	367,200	418,200	24,630
TOTAL	61,575	435,200	435,140	295,800	846,600	537,200	261,800	251,600	452,200	463,200	61,575

Alternatives E and F provide the greatest potential benefit to fish habitat due to habitat improvement as they would allocate the most dollars and have the least resource development. Alternatives B, C, I and J show similar expenditures for fish habitat improvement but under Alternatives B, I and J, a relatively large portion of the funds are KV monies tied to greater timber harvest levels compared to Alternative C. With Alternatives B, I and J there is greater risk that full potential benefits would not be achieved. This is because these alternatives have a greater amount of resource development, therefore a greater risk exists that habitat improvement funds will be needed to mitigate resource management activities. Alternative NC poses the greatest risk of not achieving habitat improvement objectives because Forest-wide Riparian Standards would not apply. Thus, under this alternative, there is the greatest risk that habitat improvement work would be directed towards mitigation.

4) Effects of Timber Management on Fisheries

Large trees and woody material are very important to fish habitat. Tree canopies provide shade in the summer and insulation in winter, moderating changes in stream temperature. Trees and their root systems help stabilize unstable slopes reducing the frequency of mass soil movement. Trees and other vegetation also protect surface soils from eroding, and filter surface soil movement which reduces accelerated sediment input to channels. Stream channel stability also is often dependent upon trees and their root systems to anchor banks.

Probably the most important interaction between trees and fish habitat occurs as the trees and large woody material enter channels. In-stream woody debris helps create a complex aquatic habitat by forming pools, providing low velocity refuge areas and cover, trapping spawning gravel, adding nutrients to the stream and regulating the routing of sediment.

Removal of timber along streams can reduce the availability of large wood input to channels resulting in a reduction in stream habitat complexity and quality, more rapid degrading (down-cutting) of channels and increases in stream temperatures.

Removal of trees on hillsides can result in an increase in the frequency of surface erosion and mass wasting. In addition, logging practices such as ground skidding can compact and expose soils thereby increasing erosion potential. Stream flow regimes may also be altered by timber harvest, depending on the harvest intensity in a drainage.

The riparian management prescription and Best Management Practices (BMP's) are designed to reduce adverse impacts to fish habitat. However, the more area harvested the greater the chance of adverse impacts occurring due to administrative error and uncertainty of the effectiveness of Forest Plan Standards and BMP's.

A potential benefit of timber harvest to fisheries is the use of Knutson-Vandenberg (KV) funds collected on sales to implement fish habitat improvements and other projects benefitting the condition of the watershed. Alternatives with greater timber harvest will provide greater potential to collect KV monies, but as previously discussed, there is also a greater risk of habitat degradation. Therefore, the funds may be needed to mitigate the adverse impacts and not necessarily result in an overall improvement in habitat capability.

All alternatives have an objective to maintain and improve fish habitat capability. Alternative NC would continue timber management activities as prescribed in the old Timber Management plans. The fish and riparian standards and guidelines included with other alternatives would not apply. Protection of riparian and fish habitat would include only those measures necessary to meet minimum conditions of the Washington State Forest Practice Rules. The Forest Plan Riparian Standards are more restrictive than the State Forest Practice rules, therefore Alternative NC would have the highest risk of not meeting fish habitat objectives. With approximately 791,899 suitable acres available for timber management allocations, Alternatives B and J harvest the most timber, have the most land (approximately 77%) allocated to General Forest and therefore exhibit a relatively high risk of impacts to fisheries from timber harvest. Alternative D also has 77 percent of the land allocated to timber management, but harvests at a slower rate and therefore would have somewhat less risk than Alternatives B and J. Alternatives A/NFMA, C, H and I have a relatively moderate risk of impacts with approximately 49 percent allocated to General Forest. Of these four, Alternative I would have a somewhat higher risk because it is a departure alternative and would enter more acres in the first decade. Finally, Alternatives E, F, and G carry the least risk with 19 percent, 26 percent and 28 percent (respectively) of the available land allocated to timber production. Within an alternative, the greatest risk of effects on fish habitat are in those watersheds with most land allocated to intensive timber management. For a discussion of watersheds with the greatest risk of effects, refer to the Soil and Water Cumulative Effects section in this chapter.

5) Effects of Range Management on Fisheries

Livestock grazing can produce adverse impacts on fish habitat by reducing cover for fish, altering stream temperature, causing a decrease in low stream flow due to alteration of stream bank storage capacity, altering stream chemistry, trampling banks and increasing sediment deposition. Riparian habitat standards designed to protect fish habitat would apply to grazing allotments under all alternatives except Alternative NC. Fishery budgets for all alternatives also include monies to monitor riparian habitat in allotments and coordinate with the range program. As with other land management activities though, generally the greater the grazing use, the greater the potential for adverse fishery impacts.

Alternatives NC and A/NFMA have a progressive reduction in permitted livestock use due to range budget constraints which would mean that improvements would not be replaced in order to increase permitted use. Permitted use would also have to be reduced to mitigate adverse environmental effects. Grazing under Alternative A/NFMA, will be restricted to existing allotments on approximately 10 percent of the Forest. However, risk of adverse impacts is relatively high as reductions would be based on resource damage.

Alternatives B, D, E, G, H, I and J would allow an increase in grazing over more acres. These alternatives would increase the risk of impacts to fisheries but due to increased range administration funds needed for implementation, these alternatives may actually be less risky than Alternative A/NFMA.

Alternatives C and F are less risky because the number of acres allocated to grazing would remain the same as the current situation with only a small increase in permitted use over the life of the Plan. Under all alternatives, use in the first decade would remain at the present level.

6) Effects of Mineral Activity on Fisheries

In general terms, mineral resources have little interaction with fisheries until they are explored and developed. When exploration and develop-

ment occurs, it usually involves surface or stream-gravel disturbing activities. Those activities which have the most influence on the fishery resource are suction dredging, access road construction, vegetation removal, mineral extraction and processing, waste disposal, increases in human population, and reclamation. Even though claimants holding a valid mining claim have a statutory right to mine, any activity which uses, diverts, obstructs or changes the natural flow or bed of any river or stream, or utilizes materials from stream beds, requires that a Hydraulic Project Approval Permit be obtained from the Washington Department of Fisheries or Wildlife. The Forest Service is cooperating with the State in implementing the permit process.

The effects that mineral activities will have on fishery resources cannot be determined until the location, type and timing of the proposed activity is known. As a consequence, the effects that mining would have on fishery resources as well as any differences between alternatives cannot be estimated. In relative terms, it appears that the potential for mining to cause adverse effects on fishery resources is inversely proportional to the amount of land managed as roadless area or under highly restrictive management prescriptions. Actual effects will depend upon mineral prices and subsequent activities.

7) Effects of Roads on Fisheries

Road construction is probably the greatest potential sediment source of all land management activities. In addition, improperly constructed stream crossings can block fish passage. Roads constructed in riparian areas can constrict the floodplain and channel, resulting in changes in channel morphology and associated habitat. Roads also increase recreation access and fishing opportunities but the increase in fishing pressure can result in potential over-harvest of wild stocks.

Potential impacts of roading are mitigated through design, Forest-wide Standards and Guidelines and road management (e.g. closing new roads).

Other than Alternative NC, Alternatives B and J construct the most roads and therefore have the greatest potential risk of impacts. Alternatives E

and F construct the least number of new roads and have the least potential for impact. The remaining alternatives ranked from most potential for impact from roads to the least potential are Alternatives D, H, I, C, A/NFMA and G

b. Cumulative Effects of Each Alternative

Cumulative effects on the fisheries resource resulting from implementation of an alternative could be of either a positive or negative nature. The primary positive effect is the potential for increased fish production due to the renewed emphasis on fisheries. The negative cumulative effects, and the ones of particular concern, are the potential reductions in the capability of the habitat to produce fish due to man's activities. For a discussion of the potential cumulative effects due to implementation of alternatives, see the Cumulative Effects section in the discussion for Soil and Water.

In addition to the potential for cumulative effects of land management activities impacting fish resources on the Wenatchee National Forest, changes in fish production on the Forest combines in a cumulative nature with the effects of other Forest Plans and management activities within the Columbia Basin. For a discussion of the cumulative effect of implementing Forest Plans on Columbia River fisheries, see Forest Plan Aggregate Outputs and Effects, Staff Paper for the Regional Forester, Region 6 (Draft August 5, 1988). This report is updated as Forest plans are completed.

c. Conflicts With Other Agency Plans and Policies

An objective of the Wenatchee National Forest Plan is to manage fish and riparian habitat so as to at least maintain current fish habitat capability and to improve habitat over time. This objective is consistent with the objectives of fish management agencies and Tribes for fish production in the lakes and streams on the Forest. Currently, the Northwest Power Planning Council is exploring ways to increase anadromous fish production in the Columbia Basin, with a goal of doubling current production levels. The Forest-wide Fish

and Riparian Standards and the EW-2 Prescription are established to protect existing habitat and provide the conditions and programs necessary to improve habitat capability.

All alternatives should result in improved habitat. Actual fish production increases will also depend upon the success of programs implemented by other agencies to improve downstream habitat conditions. As discussed in this chapter and in the discussion of alternatives in Chapter II of this document different alternatives include different levels of risk associated with maintaining and improving habitat. A summary of the relative risk associated with alternatives is displayed in Table II-1.

d. Mitigation Measures for Fisheries

Two mitigation measures designed to maintain and improve fish habitat are common to all alternatives except Alternative NC: Forest-wide Riparian Standards and the EW-2 Prescription, and the Best Management Practices (BMP's). The Riparian Standards would not apply to Alternative NC since they are not contained in the current Timber Management Plans. Under Alternative NC, streamside or riparian area management would only include those actions necessary to meet the minimum conditions established by the Washington State Forest Practice Rules and Regulations.

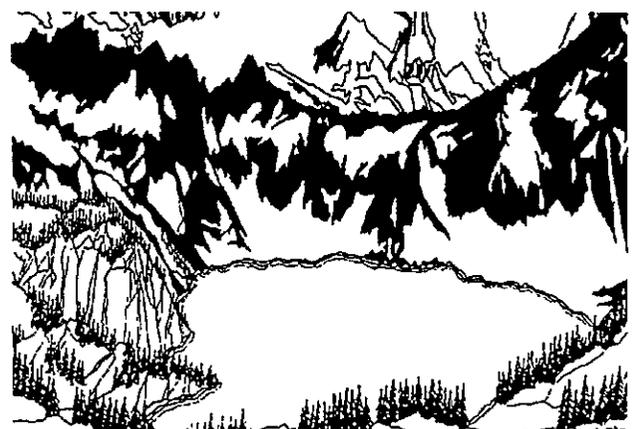

Riparian Standards and EW-2 Prescription

Forest-wide riparian standards and guidelines are developed to manage riparian areas to provide habitat conditions necessary for production of riparian-dependent resources, including fish habitat. The standards are developed to recognize the unique values of riparian resources and give preferential treatment to riparian dependent resources where management conflicts exist. Measurable standards have been established for habitat components that are felt to be the most important in maintaining fish habitat capability, including temperature, sediment, large wood and pool habitat and riparian vegetation. These standards apply to all of the Forest and management activities. In addition, standards have been developed to guide management activities adjacent to non-fish-bearing perennial and intermit-

tent streams, to minimize potential adverse impacts on downstream fish habitat.

There is currently no special land designation or standards for managing riparian areas other than manual direction and the Washington Forest Practice Rules and Regulations. A common mitigation measure now used is to work with project design to avoid or minimize impacts to riparian resources. For example, timber harvest units are often established so trees are maintained for stream shading or bank stability and a bridge may be constructed in lieu of a culvert to allow fish passage. The effectiveness of these mitigation measures often depends upon the amount of input available during project planning. Implementation of the Riparian Standards and EW-2 Prescription should help managers better design activities to minimize/avoid impacts based upon not only the site but also sub-drainage conditions. The actual effectiveness of the standards and prescription will need to be monitored as the Plan is implemented and adjustments made as monitoring results are compiled.

Best Management Practices (BMP's) A Best Management Practices Appendix (Appendix J) has been added for all alternatives except NC. Best Management Practices are practices designed to meet the Clean Water Act and reduce the potential for non-point source pollution entering stream channels. The BMP Appendix provides a guide for conducting land management activities. Actual BMP's to be incorporated into any activity will need to be developed based upon the individual project and site conditions. For further discussion of BMP's and watershed mitigation, refer to the Soil and Water mitigation section in this chapter.

9. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON VEGETATION

Under this general "Vegetation" heading, a number of topics will be addressed including: (a) Trees, (b) Old Growth, (c) Forage, (d) Unique Ecosystems, (e) Threatened, Endangered and Sensitive Plants and, (f) Research Natural Areas. Related effects on biological diversity will be discussed under each of these headings. Diversity is really an issue that encompasses all of the vegetation issues listed above. Nowhere is this more true than with old growth. Consequently, within the old growth section below, the main consequences of the alternatives on diversity will be presented.

Vegetated areas that do not change by alternative include the Entiat Experimental Forest, Tumwater Botanical Area, wilderness, existing Research Natural Areas, and biologically unsuitable, forested areas. These occupy approximately 45% of the forested acres.

9(A) ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON VEGETATION - TREES

a. Direct and Indirect Effects of Each Alternative on Vegetation - Trees

1) Effects of Recreation on Vegetation - Trees

The primary effect of recreation on trees and the timber program is through allocation of land to maintain or enhance the recreation setting. Developed campgrounds and ski areas are managed for long term sustained yield of industrial wood. Trees within these areas are harvested and some are used for sawlogs, others for firewood. However, these trees are not part of the allowable sale quantity. They are included in the timber sale programed quantity. There is little difference between alternatives in the effect of recreation on trees. Related effects of unroaded recreation and scenery do change significantly by alternative.

2) Effects of Unroaded Areas on Vegetation - Trees

Unroaded area prescriptions vary in the amount of harvest allowable, from planned but expensive in the RE-4, to not allowed in RE-3.

In all unroaded prescriptions periodic fires, insect epidemics, and disease attacks are expected to be more common and extensive than in areas of less restrictive harvest and roading.

The inventoried roadless areas encompass 26 percent of the Forest (556,000 acres). This is in addition to the 841,000 acres (39%) of the Forest in wilderness.

The amount of roadless area with restricted or no harvest is one of the primary differences between alternatives. It has a dramatic effect on harvest level. The amount of inventoried roadless area assigned to unroaded management prescriptions varies from 36,397 in Alternative NC to nearly 500,000 acres in Alternative E (See Table II-3a for the other alternatives). Alternatives J, B, D, A/NFMA and H have less than 250,000 acres assigned to unroaded, which is less than 50 percent of Alternative E. Alternatives C and I are intermediate with approximately 300,000 acres. Alternatives F and G although less than E, still allocate 78 and 69 percent respectively of the inventoried roadless to non-scheduled harvest allocations.

3) Effects of Scenery on Vegetation - Trees

Retaining the scenic qualities on the Forest has an impact on the allowable sale quantity, the average tree size, and species selection. Approximately 70 percent of the Forest has visual quality objectives that have an influence on harvest level.

Where partial retention or retention standards are applied, decreased yields and increased costs usually occur. Yield losses result from maintaining trees past their maximum growth potential and from increased disease and insect damage.

The scenic travel corridor prescriptions allow for clearcutting, especially where disease and insect problems are severe. More commonly, seed trees of the preferred species that are not diseased can

be left. Due to their resistance to decay and longevity, the preferred species are ponderosa pine and western larch. Less desirable species are lodgepole pine, grand fir, western hemlock and Engleman spruce because of their thin bark or susceptibility to disease, insects or wind throw.

Acres allocated to retention and partial retention harvest prescriptions by alternative are shown below in thousands of acres.

**TABLE IV-11
ACRES ALLOCATED TO RETENTION AND PARTIAL RETENTION**

Alternative	A/NFMA	B	C	D	E	F	G	H	I	J
M Acres	313	174	326	121	293	391	304	310	326	120

As can be seen from this chart, Alternatives J, D, and B are least affected by scenery allocations. Alternative F has the largest effect on tree management due to scenery constraints, and the remaining alternatives are intermediate.

4) Effects of Wildlife on Vegetation - Trees

There is some minor direct effect on trees from wildlife browsing and trampling. The primary damaging animals are pocket gophers, porcupines, and ungulates. On a Forest-wide basis, their effect is minor and is somewhat offset by the positive effects of browsing on competing vegetation, especially by deer and elk.

The indirect effect of the allocation of land and wildlife trees is more significant. A two percent reduction in allowable sale quantity (ASQ) due to wildlife trees was applied to all alternatives.

In addition the 2,200 acre dedicated Spotted Owl Habitat Areas (SOHA's) are not planned for harvest. Pine marten, piliated woodpecker and three-toed woodpecker areas are proposed for harvest, but at a level that will maintain mature habitat while producing a reduced yield of wood. This will mean larger trees, longer rotations, and greater snag levels than in General Forest. It may also mean increased risk of fire, insect and disease losses.

Although there is some variation in the effect by alternative, it is not significant when compared to other issues.

5) Effect of Fisheries on Vegetation - Trees

The management of fish habitat creates an indirect effect on trees through prescriptions that propose larger trees, longer rotations, less clearcutting, and a bottom line reduction in tree utilization for wood products. The vegetative effect will be to increase the number of shade-tolerant tree species, especially western red cedar, western hemlock, and true firs. The expected long term effect will be a reduction of ponderosa pine, Douglas-fir, and other species that respond well to full sunlight.

There is little difference between the alternatives in the actual effect of fish and riparian management on trees, as all streams, lakes and ponds will receive consideration in all alternatives.

6) Effects of Timber Management on Vegetation - Trees

As discussed in Chapter III, the tree-covered lands can be separated into at least two general classifications. These are (1) dry forest, and (2) moist forest ecotypes. The timber inventory originally contained a third category of less than 5,000 acres, the lodgepole pine/mountain hemlock ecotype. Only one inventory plot was lo-

cated within it. Because of the small size and lack of information concerning this latter category, it was combined with the moist ecotype, where it was found to be suitable for long term, sustained yield of commercial industrial wood production.

Both even and uneven-aged silvicultural systems are planned for use in all ecotypes. However, past attempts on the Forest with selective systems has resulted in many acres of "high graded" stands of small diameter, low value species with unacceptable growth rates and high mortality.

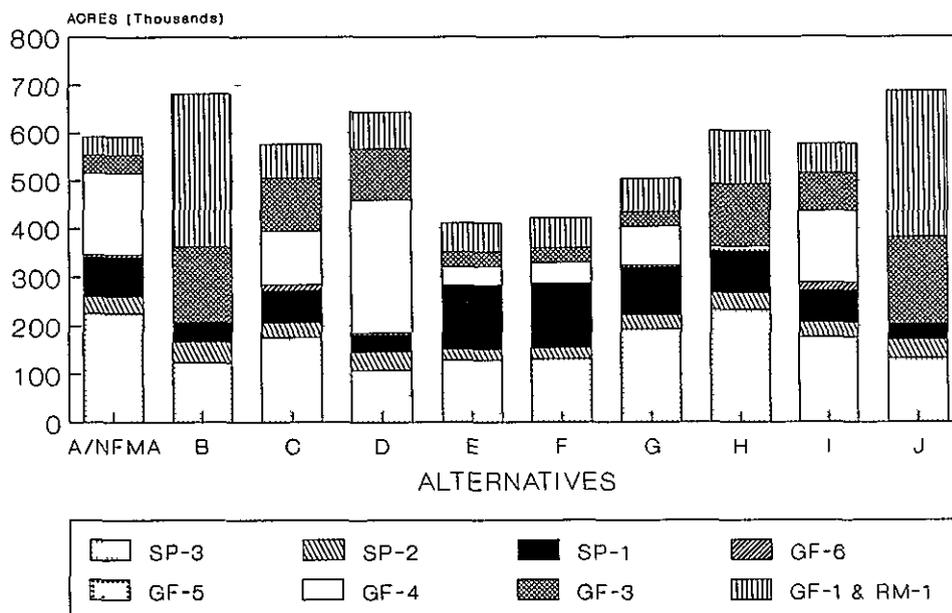

No alternative was drafted specifically to address uneven versus even-aged management. The Forest instead selected an intermediate system, referred to as extended shelterwood, that combines the constant tree cover protection of riparian areas, scenery, and wildlife benefits of uneven-aged management with the desirable characteristics of even-aged management. The

desirable characteristics of even-aged management that are deemed important are a definite regeneration check point, control of species, and reduced harvest entries. The lower number of harvest entries reduces logging costs, as well as soil, water, and wildlife impacts.

The percent of the harvest coming from areas where this type of management is the preferred option is shown below. The actual silvicultural prescription applied to a given acre will depend on site specific evaluation criteria developed during the environmental analysis and documented by a certified silviculturist

The amount and the objectives of vegetative manipulation will vary between alternatives. This is shown in Figure IV-5. The bar length for each alternative shows that portion of the forested acres suitable for timber harvest under each alternative and how these acres are allocated.

FIGURE IV-5
ACRES BY TIMBER YIELD TABLES

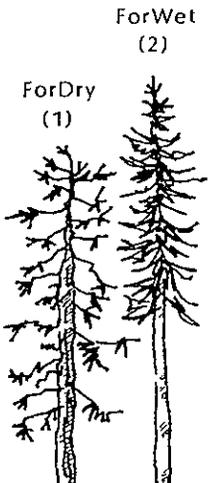

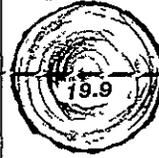

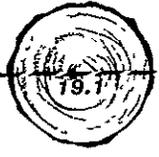

The General Forest (GF) Yield tables include three levels of intensity of management. These options or intensities are:

1)GF-1 - Highest intensity option. Includes precommercial thinning and release if needed, two commercial thinnings, and final harvest generally at culmination of mean annual increment. Final harvest is assumed to be clearcut unless shelterwood is needed to assure regeneration within five years.

2)RM-1 - This option is identical to GF-1 except that forage is to be managed in addition to trees. This may decrease tree growth during the first 10 years. Because relatively few acres are allocated to this option, it is combined with GF-1 in the preceding Figure IV-5.

FIGURE IV-6
TIMBER YIELD TABLES - GENERAL FOREST

		GF-1		GF-3		GF-4		GF-5		GF-6	
	Average Annual Growth at Culmination (CMAI)	52.3	60.3	51	58.1	44	57	49.7	61.6	42.3	55.1
	Cubic Feet / Acre / Year	(1)	(2)	(1)	(2)	(1)	(2)	(1)	(2)	(1)	(2)
Diameter at Breast Height at CMAI	ForDry (1)										
	ForWet (2)										
Natural Regeneration		10%		10%		10%		60%		40%	
Plant		90%		90%		90%		40%		60%	
Pre-Commercial Thin		✓		✓		0		✓		0	
Commercial Thin		age 70-90		0		0		age 70-90		0	
Shelterwood		0		0		0		✓		✓	
Clearcut		✓		✓		✓		0		0	
Cost Most (4)→Least(1)		4		4		3		2		1	
# of Trees per Acre		58	54	227	201	305	400	58	53	305	369
CMAI - Age		120	110	70	100	100	110	124	164	104	124

3)GF-3 - Moderate intensity option. Includes precommercial thinning and release if needed, but no commercial thinning. Final harvest generally at culmination of mean annual increment is assumed to be clearcut unless shelterwood is needed to assure regeneration within five years.

4)GF-4 - Low intensity option Includes no planned thinnings. Final harvest generally at culmination of mean annual increment is assumed to be clearcut unless shelterwood is needed to assure regeneration within five years.

5)GF-5 - Identical to GF-1 except that this option uses shelterwood harvests to reduce planting costs. This option is selected only in Alternatives B and H.

6)GF-6 - Lowest intensity option. Identical to GF-4 except that this option uses shelterwood harvest to reduce planting costs. This option is selected in all alternatives except G and H, but on relatively few acres.

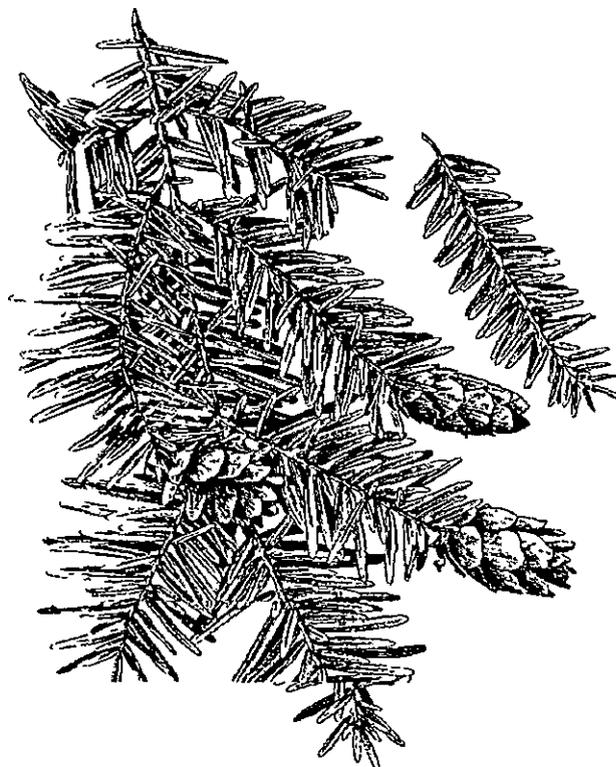

It should be noted that shelterwood harvests may be used in all alternatives and on additional acres if needed to assure regeneration within five years. This determination will be made by certified silviculturists, as called for by the National Forest Management Act of 1976, based on biological rather than economic considerations. For each intensity level, see Figure IV-6 for details on expected yields in cubic feet, tree sizes, amount of planting, commercial thinning ages if appropriate, number of trees per acre, and approximate rotation age at final harvest.

The Special Prescription (SP) Yield table includes three variations in timber yield associated with other resource emphasis allocations.

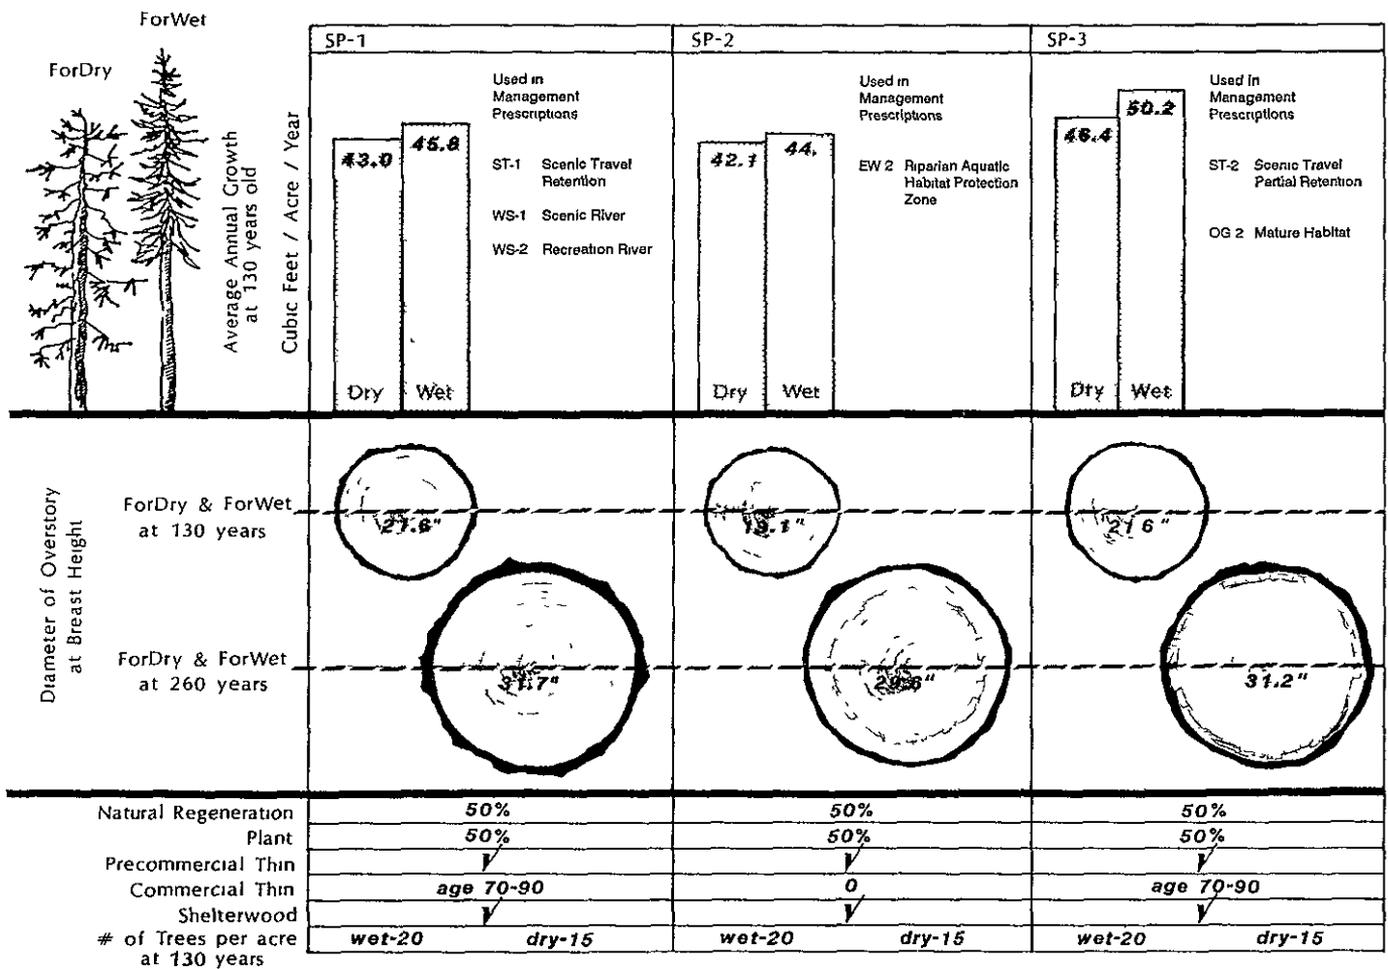

1)SP-1 - Calls for long rotations of up to 260 years to produce large trees (24 to 36 inches in diameter). As shown in Figure IV-7, this yield table is used in management prescriptions for old growth, scenic travel retention, as well as Scenic and Recreational rivers. See Scenery, Figure IV-2 for a visual description of this prescription.

2)SP-2 - Calls for long rotations of up to 260 years. Large trees for cavity nesters, spotted owls, and big game habitat in dry areas are desired. However, disturbing the site once large trees are established is judged undesirable. Therefore, precommercial thinning is called for to help trees grow larger, but no commercial thinning of the cover-creating trees is planned. On the riparian and aquatic habitat areas this allows tree management, but reduces disturbance caused by logging.

3)SP-3 - Calls for long rotations of 180 to 260 years to produce 24 to 28 inch diameter trees. This yield table is used to simulate management for partial retention along travel corridors and to produce key big game habitat in wet ecotypes. See Scenery, Figure IV-2 for a visual description of this prescription.

**FIGURE IV-7
TIMBER YIELD TABLES - SPECIAL**

The major differences in alternatives as these relate to trees result from acres proposed for harvest, acres planned for timber stand improvement, and acres of full yield versus modified yield. Acres proposed for harvest vary from a high of 787,751 acres for the No Change Alternative to a low of 410,395 for Alternative E. As a percentage of tentatively suitable lands this ranges from a high of approximately 99 percent to a low of 52 percent. Table IV-12 below shows how this varies by alternative.

**TABLE IV-12
PERCENTAGE OF TENTATIVELY SUITABLE LAND AVAILABLE FOR HARVEST**

Alternative	N/C	A/NFMA	B	C	D	E	F	G	H	I	J
Percentage	99	75	86	73	81	52	53	64	76	73	87

The acres planned for stand improvement (i.e. thinning, spacing, weeding or release from other vegetation competition) will vary according to the objectives of each alternative. The environmental effect of increased stand improvement on trees is increased tree vigor, diameter, and disease resistance. Tree numbers, insect losses and long term fuel loadings are decreased by thinning. Short term risk of losses due to fire is increased because of the flammability of the trees and brush cut or killed by herbicides. Precommercial thinning can double the average tree size, but reduces tree numbers by an average of 50 percent. The end result is net increase in merchantable tree volume.

Those alternatives that maximize timber outputs also maximize timber stand improvements. Those that maximize PNV decrease investment in stand improvement. The lowest stand improvement acreages are in those alternatives that allocate larger acres to unroaded recreation, especially Alternatives E and F. For acres planned for stand improvement see Table II-3a in Chapter II of this document.

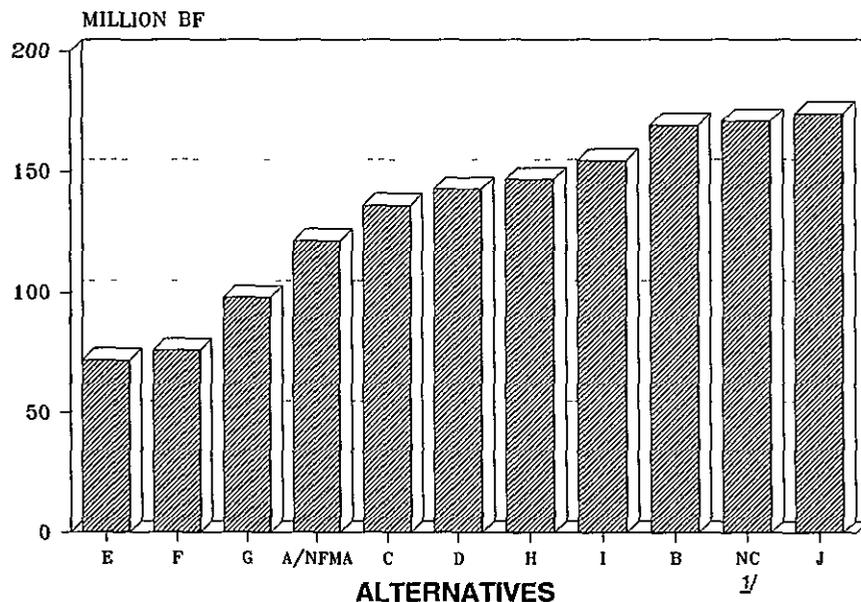

b. Cumulative Effects of Each Alternative

As discussed in the previous section, recreation, unroaded areas, scenery, wildlife, and fish concerns all affect the vegetation-trees component, and especially the allowable sale quantity, by significant amounts. Additional minor but cumulative effects on the ASQ are caused by the designation of Wild and Scenic Rivers, cultural resources, biodiversity, unique ecosystems and social concerns. All tend to reduce the potential area or ability to harvest trees.

The old growth spotted owl controversy is probably the largest single impact during the first decade as it affects the heaviest volume and most valuable stands proposed for harvest. This controversy has already changed the demand and supply picture for not only Wenatchee National Forest timber, but for the entire Region. This cumulative effect will increase costs, but should also increase the future stumpage values by at least the one percent used for modeling. This increased value results in increased management intensity that can mitigate losses in the high harvest alternatives (B and J).

The cumulative effect on the allowable sale quantity (ASQ) as compared to current sell and cut levels is shown in Figure IV-8.

**FIGURE IV-8
COMPARISON OF ALLOWABLE SALE QUANTITY**

^{1/}Current cut and sell level includes the 14 MMBF temporary inflation of the harvest

Although ASQ in all alternatives except B and I will be reduced by the cumulative effects of other resource concerns, productivity will increase on the remaining harvest acres as shown below in Table IV-13.

TABLE IV-13
TIMBER PRODUCTIVITY PER ACRE 1/

	A/NFMA	B	C	D	E	F	G	H	I	J
Productivity by year 2030 in cubic feet	26	36	29	30	24	25	21	26	31	37
Increase in Growth in percent between 1st and 5th decade.	14	46	12	14	3	7	22	47	24	75

1/ No figures are available for the NC Alternative

c. Alternatives' Conflicts With Other Agency Plans and Policies

There would be little if any conflict in tree management under any of the alternatives. The Forest is a cooperater in tree improvement with the Department of Natural Resources and Plum Creek Timber Company. This would continue under all alternatives.

Alternative B with its increase in harvest level could have a slightly depressive effect on timber values on State, private, and Yakima Indian lands. The alternatives that reduce the Forest harvest level, especially Alternatives E, F, and G, could increase timber purchasers' interest in other land-owner timber sales.

Alternatives E, F, and G would have an impact on State and local government incomes. This could affect their ability to maintain current road and school programs in Chelan, Kittitas, and Yakima Counties. See Table II-3a for the payments to Counties by alternative.

The requirement that created openings be less than 40 acres can cause scheduling problems for proposed sales near other ownerships. If the adjacent owner harvests areas larger than 40 acres, trees must be re-established and 4.5 feet tall before contiguous openings can be created on the National Forest lands.

Those alternatives with the highest harvest levels (Alternatives B, D, and I) would create the most problems with the Forest's ability to schedule sales that do not add to created openings on adjacent private lands.

d. Mitigation Measures for Vegetation: Trees

The effects of other resource activities on Vegetation - Trees and especially on the allowable sale quantity can be mitigated through intensive management.

Selection of genetically superior trees and properly matching species to individual site conditions is the first step in intensive management. Proper spacing of trees and selection of trees with good growth, disease resistance and longevity can mitigate the effects of the longer rotations called for in the scenic travel corridors, recreation use sites, and riparian areas

Wildlife damage can be mitigated through avoidance of the problems or by direct control of the animals. Leaving seed trees to replace damaged trees with new seedlings through natural regeneration can mitigate gopher and porcupine damage.

Wildlife tree impacts on harvest levels can be reduced if the trees left are those too defective to be a part of the ASQ.

As was described in Chapter III, the Wenatchee National Forest has 16 species of conifer trees. The combination of these with the variables of soil type, aspect, rainfall, and elevation create the need for a wide range of silvicultural options. Therefore, from a pure tree management standpoint, those alternatives with a mix of treatment opportunities provide the most flexibility to fit specific site needs with silvicultural prescriptions.

The complicating factor that strongly influences the selection of silvicultural prescriptions is economics. By making maximum PNV based on average costs and values the overriding objective, as in Alternatives A/NFMA, G, D, E, F, and I, few acres are allocated to high intensity management. The other extremes that select almost all management intensities that involve thinning the stands are Alternatives B and J. Neither of these approaches to selection of appropriate tree management intensities provide for the optimum level of forest management from a silvicultural perspective.

Some of the biological considerations not accounted for completely in the FORPLAN modeling are the effects of (1) mountain pine beetle, (2) variations in species reactions to density, and (3) thinning interactions with root rot and stem diseases.

Perhaps some specific examples of when thinning is particularly important will help. One example is pine pole stands. Without thinning to improve growth, trees over eight inches in diameter become susceptible to beetle attack (Sartwell 1975). With the exception of some use for firewood or chip material, there is little market for beetle-killed pine species in the local area.

Under Alternatives A/NFMA, C, D, E, F, and I, a potential mitigating measure might be to use more intensive timber management practices than those which maximize present net value. This would reflect biological factors not presently incorporated into these alternatives.

For each acre of intensive management (GF-1) versus intensive management with no thinning (GF-4) there is a calculated increase of 420 cubic feet, or 2,289 board feet, of wood production. The value of this additional volume per acre based on the 1982 stumpage value for the Wenatchee of \$94.00 per thousand (M) board feet is \$215.00 per acre (2.29 M Board feet x 94.00 = \$215.00). Due to the increased size of the trees, the value is even greater than shown by this calculation, which only recognizes average stumpage values rather than value by tree size.

A more detailed cost analysis including actual expected thinning costs, a four percent interest rate, and a one percent inflation of stumpage values was prepared for the 18,000 acres of thinning needed in the 15 year old Entiat-Chelan burn areas. This analysis found about 12,000 (or two-thirds) of the acres to be economically feasible for thinning. Only those acres on steep skyline ground needing road access, or having extremely dense, high cost thinning, were not economical.

Alternative B proposes to thin more acres than is biologically sound or economically optimum. For example, thinning should not be planned for areas of Phellinus weirii root rot. Precommercial thinning of Douglas-fir plantations is not recommended when Phellinus is present (Hanson 1975). As this disease is very common on the Wenatchee, any alternative that proposes to thin essentially all acres is not biologically defensible. A mitigation measure would be to recognize this factor and reduce the proposed acres of intensive management in Alternative B and increase the acres of GF-4 prescription.

An attempt to model an approach between the maximum PNV and the maximum timber harvest is used in Alternative G. As shown by Figure IV-5, Alternative H also has a distribution of treatment prescriptions that is in between the extremes of Alternative B and those that maximize PNV.

Under all alternatives planting will be done with a mixture of species. All species have their application or specific niche in the Forest ecosystem. Mixed species planting, as well as planting with trees from the best parent trees of each species, will help to mitigate any tendency toward monocultures that could be destroyed by insects or diseases.

Fertilization can be used in all alternatives, also. Past trials on the Forest have shown it to be an effective method of increasing growth. It could be used as a mitigation measure if harvest, site preparation, or other treatments cause a reduction in fertility.

Thinning may be used along with release from brush competition to improve the size, quality, and growth rate of young stands. Over zealous planting or natural seeding can create stands too thick for proper growth. As the National Forest Management Act of 1976 calls for optimum rates of growth, thinning or release can be used to achieve these rates if overstocking or other vegetative competition is the problem.

Shelterwood harvest rather than clearcutting is often prescribed where amelioration of temperature, solar radiation or wind is needed to assure reforestation. This mitigation measure is also used in special harvest allocation areas to protect scenic values, provide soil and water protection, or provide wildlife habitat.

Dead trees or snags will be left for wildlife in all alternatives. Both standing and fallen trees are a storage place for nutrients and habitat for vertebrate and non-vertebrate animals. Snags also provide perches for raptors that prey on rodents that eat tree seeds and seedlings.

The above mitigation methods apply to all alternatives. However, the mitigation for effects on the ASQ is least effective where more acres are removed from the suitable commercial land base.

9(B) ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON VEGETATION - OLD GROWTH

a. Direct and Indirect Effects of the Alternatives on Vegetation: Old Growth

The variation in the effects of the alternatives on old growth relates directly to the number of activities that manipulate the old growth ecosystem. Very little disturbance is required in an old growth ecosystem to cause a change sufficient to modify its function. Ground-disturbing activities obviously disrupt the normal functioning of the old growth ecosystem and must be considered a major effect. Major effects also result from any activities that significantly change the structure and composition of the old growth vegetation.

There are many indirect effects of man's activities on vegetation. It is relatively easy to establish that increases in direct physical activity like road building will result in vegetation change. However, the long term indirect effects of lack of activity in non-commodity alternatives will not necessarily assure the maintenance of more natural stand conditions over time. Unnatural buildup of woody debris (from fire suppression and lack of prescribed fire) leads to increased incidence of insect and disease outbreaks and a greater likelihood of catastrophic fire. The extent of these types of indirect changes are very difficult to predict. They are likely to be substantial

Effects of management activities on old growth may also significantly affect biodiversity. Old growth is a component of biodiversity, and is limited in abundance and distribution. Consequently, the maintenance of old growth is important to the maintenance of diversity. For this reason, diversity will also be included in the following discussion.

1) Effects of Recreation on Vegetation - Old Growth

Recreational use of the Wenatchee National Forest is ever increasing. Greater numbers of people on the landscape, and the development of campgrounds and access roads to accommodate the increase in numbers, will result in direct modifica-

tion of the vegetation. Old growth is affected by this. Generally, human caused vegetative modification will result in unnatural plants and plant communities. Site disturbance will retard or change succession.

Vegetation composition of highly used areas will change as a result of trampling, compaction and vehicular use, and noxious weeds will increase due to disturbance and the introduction of weed seeds. Old growth stands often are the target of intense recreational pressure because of the aesthetic qualities to be found there. As a result, recreational use does result in some loss of the biological attributes of old growth, although the stand may still be considered aesthetically as "old growth".

Forest-wide standards and guidelines for old growth and diversity are designed to maintain adequate amounts of old growth for its own intrinsic values and as components of biological diversity. Increased recreational use will increase the risk of detrimental impacts to old growth.

Semi-primitive recreation management protects vegetation from at least widespread, human-caused impacts. Generally, negative impacts are fairly restricted in nature. As more land is allocated to developed and roaded recreation, however, the risk of substantive impacts increases.

Alternatives with the most acres in non-motorized, semi-primitive allocations such as E (320,038 acres) and F (259,088 acres) would result in the least potential for adverse impacts to old growth from recreation. Alternatives C and I (116,092 acres) and G (100,362 acres) would have somewhat greater risk of damage to the old growth resource than E and F, while alternatives with the least land allocated to semi-primitive, unroaded allocations (B, D, J, H, A/NFMA and NC) would have the greatest potential risk of adverse impacts to old growth. Alternative NC would pose the greatest risk because Forest-wide standards and guidelines for old growth, diversity and recreation management would not apply.

2) Effects of Timber Management on Vegetation - Old Growth

Timber harvest is the primary means of manipulating vegetation on the Forest to achieve the desired management objectives for timber, range, recreation, wildlife, and visual resources. There are a number of related activities associated with the establishment, tending, harvest, and marketing of forest stands including: road construction and maintenance, logging operations, treatment of slash, site preparation, reforestation and control of stand composition and density. All these types of activities affect the vegetation resource.

At this time, it is felt that any significant harvest activities in old growth stands essentially eliminates those stands from the designation of "old growth". Consequently, the amount of old growth Forest within each alternative is related to the amount of harvest activity.

Old growth amounts over time by alternative are displayed below in Table IV-14.

TABLE IV-14
ACRES OF OLD GROWTH REMAINING
(INCLUDING WILDERNESS)
AT THE END OF DECADES 1, 2 AND 5

Alternatives	Decades		
	1	2	5
NC	305,100	291,400	250,400
A/NFMA	307,300	295,800	261,600
B	305,200	291,500	250,700
C	307,300	295,700	261,200
D	305,900	293,100	254,500
E	310,600	302,400	277,700
F	309,300	300,900	275,700
G	299,600	289,500	259,300
H	306,700	294,600	258,400
I	307,300	295,300	261,200
J	305,100	291,300	250,100

Generally, the harvest rate of old growth forest is higher in the alternatives that have higher levels of timber harvest. The amounts in the table are based upon current acres of old growth and their decrease over time, predicted by subtracting the estimated acres of old growth harvested in each decade by alternative. The remaining old growth acres do not, however, reflect any possible additions resulting from ingrowth (i.e., the development over time of old growth stands from stands that previously did not exhibit old growth characteristics). The average age of mature stands on the Wenatchee is approximately 150 years (estimate from timber inventory data). Approximately 30 percent of the forested stands on the Forest fit into this category. Although some of these mature stands have been disturbed recently, there are many stands that have the potential to become old growth in the near future. Consequently, some old growth will develop with time and should increase the amount of old growth actually remaining in each alternative. Alternatives with greater amounts of no-harvest allocations should accrue old growth at a relatively faster rate because fewer stands would experience the disturbance that might preclude old growth development in the near future (see Table II-3a in Chapter II).

Old growth is an important component of vegetation diversity. Vegetation diversity, in turn, is an important component of total biological diversity. Old growth forest is a vital cog in the maintenance of diversity. Both distribution and abundance are important considerations in assessing old growth--especially as it contributes to diversity.

Vegetation diversity is predicted to vary by alternative in the same way that total biological diversity does. A rating of biological diversity by alternative is presented in Table II-3b, in Chapter II. Generally, the distribution and number of plant and animal species will be highest in the amenity alternatives (E, F and G) and lowest in the commodity alternatives (B, N/C and J). The other alternatives are either moderate (A/NFMA and C) or low to moderate (D, H and I) in diversity.

Another consequence of timber harvest activities is the change in corridors that provide avenues for genetic flow. An important corridor will be available in all alternatives except N/C in the form of riparian areas, as described in the riparian area management prescription. However, as higher proportions of the landscape are included in timber harvest allocations, there will be fewer undisturbed corridors to allow for genetic flow between undisturbed "islands" of vegetation for species that require such environments. This has been a particular concern of those individuals interested in old growth forest maintenance. N/C will have the fewest corridors over time, followed by J and B (the highest timber alternatives). Alternatives E and F will have the greatest number of undisturbed corridors. Of the middle-harvest-level Alternatives D and H, D will have the fewest corridors, due to the heavier roading. Alternatives A/NFMA, C, G and I will have a moderate number of corridors available.

Old growth forests are typically in mid-seral to near climax condition. Generally, alternatives that have more acres excluded from timber harvest will have a greater land area in more advanced stages of successional development. The amenity Alternatives E and F and Alternative G would result in more of the advanced seral stage stands over time. Alternatives B, N/C, and J would produce fewer of these higher seral stage communities.

There are some indirect effects of the timber management program on old growth. In Alternatives E and F, the existing vegetative character may be at risk of high intensity wildfire and/or epidemics. It will be difficult to prolong the character of older age classes without an active program of fuel and stand maintenance, which are usually tied to an active timber management program. Intense harvest activities may also cause too much fragmentation of old growth, essentially reducing the effectiveness of small old growth stands in maintaining old growth ecosystem attributes.

3) Effects of Range Management on Vegetation - Old Growth

Grazing can impact old growth ecosystems mainly through vegetation modification and soil compaction. Old growth forest in upland locations will likely not be impacted much by grazing, except perhaps open stands of ponderosa pine or in some cases, Douglas-fir. Most old growth stands are dark, with little available forage, and consequently most of these areas are not grazed by livestock. Use and the possible resultant damage to old growth stands would mainly be restricted to riparian areas and adjacent stands where animals might go for shade. In the first two decades there is no significant difference between the alternatives. By the fifth decade Alternatives B, D, E, G, H and I would have heavier grazing use than the other alternatives and as a result, more resource damage to old growth would be expected in these alternatives. However, it is likely that most old growth stands will not be significantly impacted by grazing.

4) Effects of Mineral Activity on Vegetation - Old Growth

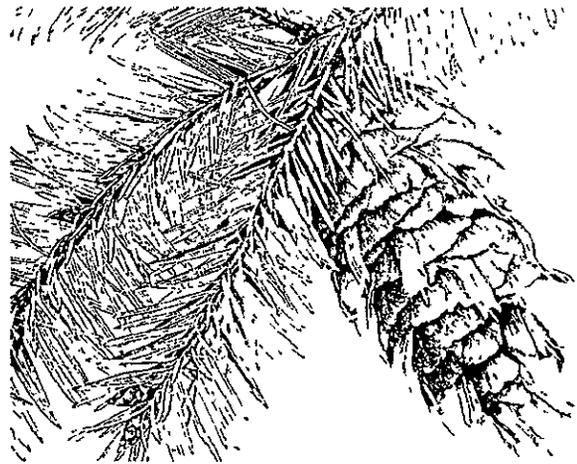

Like road construction, mining activities often result in movement of earth and direct habitat modification that can be severe in nature. Those activities with the most influence on vegetation will be access road construction, mineral extraction and processing, waste disposal, increases in human use and reclamation activities. Generally, claimants holding a valid mining claim have a statutory right to mine and this right supersedes law and policy that protect vegetation from modification or destruction. The extent of the effects of mineral activities on old growth cannot be determined until the location, type and timing of the proposed activity is known. As a consequence, the impacts that mining would have on the amount and distribution of old growth by alternative cannot be estimated.

5) Effects of Roads on Vegetation - Old Growth

Road construction causes significant ground disturbance and is associated with many activities on National Forest lands. The major impacts of roading on old growth are both direct and indirect. Direct effects are physical site modification

along the right-of-way. Succession is set back when portions of old growth vegetation are removed. Indirect impacts of roads include changes in site hydrology, which may change the character of adjacent old growth forest stands. Other indirect impacts of roads are increased access and traffic leading to higher use levels, the disturbance of corridors important to genetic flow, and excessive fragmentation of old growth stands.

Alternative NC has the most roads followed by Alternatives J and B. These alternatives would have the highest risk of adverse impacts. Alternatives E and F construct the least number of new roads and have the least potential for adverse impacts. Table II-3a in Chapter II displays the miles of new road construction by alternative.

b. Cumulative Effects of Each Alternative

All alternatives will reduce the "natural" character of the vegetation through timber harvest, roading, recreational use and the myriad of other activities associated with the multiple use of National Forest System lands. The rate at which these modifications occur and the risk of error are what change by alternative. Cumulative effects are also the result of activities on lands owned by other parties. This section will discuss the effects of various activities on old growth attributes regardless of ownership.

Currently, private and state-owned lands reflect management activities that are highly commodity oriented. Consequently, in areas of intermixed ownership, the cumulative effects and risk of Forest Service alternatives that are also commodity oriented becomes very high. Forest Service lands become the critical links in the maintenance of old growth.

Old growth will decline in all alternatives. There should be enough old growth maintained (at least in the short term) to meet legal requirements for diversity. Alternatives E, F and G will have the greatest maintenance of the natural character of the landscape over time. Indirectly, however, the influence of insects, disease and fire may result in major cumulative effects on old growth--perhaps even greater cumulative effects than the more commodity oriented alternatives would have. With fire suppression activities, fuels will build up to unnatural levels, increasing the fire hazard. Residue amounts that are higher than would naturally occur, may also result in a higher incidence of insects and disease. It will be very difficult to maintain the natural character of the stands over time, considering that the fire, insect and disease outbreaks will be the result of unnatural circumstances.

Alternatives A/NFMA, C, I and H will have intermediate levels of timber harvest and roading so that the cumulative effects of these types of activities should be more than in Alternatives E, F and G but less than in the high commodity Alternatives D, B and J. The indirect effects on old growth of increased fire intensity and insect and disease outbreaks should be somewhat less than Alternatives E, F and G.

Alternatives D, B, J and NC have the highest commodity outputs. The amount of direct ground disturbance is directly proportional to the commodity output levels. Consequently, the amount of old growth is less and the risk of error in maintaining diversity and sensitive plant species is higher. This is especially true in Alternative NC where no standards and guidelines have been developed, and the policies and laws have not been interpreted for on-the-ground application.

It may be difficult if not impossible to maintain the corridors and amount of old growth necessary to support adequate diversity in the commodity alternatives. However, at this time the quantity and distribution of old growth necessary to meet legal requirements for biological diversity are not established. The risk of unnatural fire and insect and disease outbreaks resulting from high residue build up are reduced though.

c. Alternatives' Conflicts With Other Agency Plans and Policies

No conflicts are anticipated between the effects of the alternatives and other agency plans and policies

d. Mitigation Measures for Vegetation - Old Growth

There are a number of mitigation measures incorporated in the Forest Plan for the maintenance of old growth. Any mitigation measures in the Plan are applicable to all alternatives except NC. Measures required by law and policy are universally applicable. Mitigation measures applicable to all Forest Service activities are primarily addressed through land allocations, standards and guidelines and capital investments. Laws and Forest Service policy are also, to some extent, mitigation measures.

Generally, mitigation measures that are used in relation to vegetative attributes that are in limited abundance (like sensitive plants and old growth) are those that: 1. Avoid impact by not taking a certain action or parts of an action; 2. Minimize impacts by limiting the degree or magnitude of the action and its implementation or; 3. Reduce or eliminate the impact by preservation and maintenance operations during the life of the action. Repairing, rehabilitating, or restoring the affected environment are generally not effective means of mitigation for old growth. In the case of old growth (including diversity) sometimes substitute resources or environments can be provided.

Standards and Guidelines in the Forest Plan for old growth include strategies of management to maintain old growth for diversity, wildlife and plant habitat, and aesthetics. The Forest has also enumerated goals for old growth and diversity. Further, Forest Service policy and laws (in some cases) provide management requirements for the maintenance of diversity (to which old growth contributes).

**9(C) ENVIRONMENTAL
CONSEQUENCES OF THE ALTERNA-
TIVES ON VEGETATION: FORAGE**

This section describes the direct and indirect effects of the alternatives on the forage portion of the vegetative environmental component. As discussed in Chapter III, vegetation types within the Forest evolved through the natural interactions of climate, wildfire occurrence, and grazing animals. Fire removed or thinned the trees while large grazing animals used and modified the resulting forage resource.

Utilization of forage will cause vegetative changes, including changes in numbers and species of plants and the growth habit (both size and shape) of some plants. When grazing by livestock is continuous and unmanaged, the changes in numbers and species of plants can be detrimental to the forage base, as well as to the soil and watershed resources. However, when grazing use is controlled through intensive management systems, the results can have a beneficial effect by increasing plant vigor and numbers of desirable forage species. This, in turn, can improve soil and watershed condition. Hormay (1970) observed that species composition of the vegetation changes continuously. It changes slowly in natural succession but may change rapidly under the influence of forces such as grazing or fire. Hormay also noted that cattle use of bitterbrush caused a change in form which resulted in both an increase of annual leader growth, and protection of a percentage of this growth from grazing due to crown hedging. Observations have been made which compares responses to different intensities of grazing with reproductive response of some grass species. Significantly more bluebunch wheatgrass seedlings become established under intensive management systems than under continuous grazing or where grazing has been eliminated.

Savory (1984) observed that lack of forage use on low rainfall areas (brittle environments) can cause poor water cycling, poor mineral cycling, and poor energy flow (sun's energy converted to forage). This will result in loss of vegetation and the exposure of soil to wind and water erosion. This same observation has been made on the Forest within animal exclosures on drier sites.

The above discussion provides the key elements in determining the direct and indirect environmental consequences of the alternatives on the forage within the vegetation component. The numbers of livestock available to use as a management tool are the same in all alternatives in the first decade (see Table IV-15). Numbers of permitted livestock vary by alternative after the first decade, with the greatest variation coming in the fifth decade. The number of acres of suitable forage that will be available to livestock use also varies by alternative.

TABLE IV-15
EXPECTED PERMITTED USE IN THOUSANDS
OF ANIMAL UNIT MONTHS

Decade	Alternative										
	NC	A/NFMA	B	C	D	E	F	G	H	I	J
1	23.0	23.0	23.0	23.0	23.0	23.0	23.0	23.0	23.0	23.0	23.0
2	23.0	23.0	25.5	24.0	25.5	25.5	23.0	25.5	25.5	25.5	25.5

1/ These acres include both existing suitable and potentially suitable lands after vegetative manipulation through timber harvest

a. Direct and Indirect Effects of Each Alternative on Vegetation: Forage

There are several environmental components and/or activities that, due to their nature or scope, have little effect or a minor constant effect by alternative on the forage base. These environmental components and/or activities include; Wild, Scenic and Recreational Rivers, Cultural Resources, Scenery, Wilderness, Fisheries, Water and Soils, Air, and Minerals. The minor effects of these environmental components or activities on forage are not discussed below.

1) Effects of Developed Recreation on Vegetation: Forage

Most developed recreation sites are fenced to exclude livestock, and heavy seasonal use by recreationists generally excludes forage use by wildlife. Developed ski areas are an exception, and ski runs do provide forage for big-game. These effects of developed recreation on forage are directly related to the number of acres allocated to developed use. Alternatives NC, E, H and A/NFMA would have the least effect on available forage as a result of the lowest acres allocated to developed recreation. Alternatives C and I would be next followed by Alternatives F and G. Alternatives B, D and J would have the greatest number of acres allocated to developed recreation.

2) Effects of Dispersed Recreation on Vegetation: Forage

There are 36 recreation livestock allotments on 30,000 acres of suitable rangelands. Approximately 13,500 head of recreation livestock grazed on the Forest in 1988, with most of this use occurring in unroaded and wilderness allocations. This use is expected to increase in the future until limited by user or resource conflicts. Alternatives which provide more unroaded and wilderness recreation opportunities will provide more area for use by recreation livestock owners, and reduce the probability of future user and resource conflicts. Alternatives E, F and G have the most land allocated to the combination of unroaded and wilderness areas, and will provide the most recreation livestock forage. Alternatives C and I are next, followed by A/NFMA and H. Alternatives B, D and J have fewer acres available while NC would have the least available for recreation livestock forage use.

3) Effects of Wildlife and Livestock on Vegetation: Forage

The forage base occurring on the Forest will be utilized to some degree by either wildlife or livestock, and in some cases both classes of animals will use the same forage at different times of the year. Forest-wide there is forage in excess of current and projected needs. However, where some key winter range areas are utilized by livestock in the summer, there may be reductions in forage below the needs of wildlife. Wildlife use different vegetative areas depending upon the season of the year and also depending upon the severity of the winter. In mild winters with low snow depths, wildlife will use higher elevations, which greatly increases the size of their winter range. It is only in the more severe winters where deep snow forces animals into smaller areas that competition for forage becomes significant. Livestock can be managed to reduce or eliminate this competition. However, competition between wildlife of the same species or between elk and deer can only be controlled by reductions in numbers through hunting.

Wildlife habitat can be managed through use of vegetative manipulation, livestock grazing, and prescribed fire. Fire, as an alternative, can have some adverse consequences including the exposure of soil to erosive processes by reducing plant density. It is difficult to manage wildlife in order to achieve the desired effect on the forage resource. The Department of Game is expected to continue to feed elk in the winter which will maintain elk numbers above the natural habitat capacity. The Wenatchee National Forest contains between 10 and 20 percent of the winter range available to wildlife in this area. Livestock use, in combination with vegetation manipulation through timber harvest and some prescribed use of fire, becomes the primary tool for management of the vegetation on the Forest. Scotten (1980) notes that the scale of operations in logging and range livestock production in the west provides tremendous opportunities for improving wild ungulate habitats.

Alternatives NC and A/NFMA have 406,872 acres available for livestock grazing, and between 20,000 to 23,000 AUM's of permitted livestock use. All use will be within existing allotments. There will be 495,099 acres of suitable forage outside of existing allotments that will not be used by livestock. Palatable brush species in some habitats will grow out of reach of both wildlife and livestock within 5 to 10 years after timber harvest. There will be areas in the low elevation dry vegetative types that will not be used which may result in loss of plants needed for soil protection. This effect will be greater in decades three through five when livestock numbers are reduced. In addition, some areas such as riparian zones will be heavily utilized due to loss of fences in the last three decades. Heavy annual utilization in this zone and other concentration areas will result in loss of plants and further reduce the forage base.

Alternatives B, D, H, I and J have, respectively, 907,900, 902,753, 893,642, 898,184 and 908,200 acres available to use for livestock grazing, and there will be between 23,000 and 36,000 AUM's of permitted grazing use, depending on the decade. These alternatives have a high level of existing and potential forage and moderate to high number of livestock to use as a tool to manage the forage base. There may be some loss of forage through natural succession or lack of

utilization, particularly in the first two or three decades. By the end of the fifth decade, there will be from 41,000 to 85,000 acres of suitable forage that will not be used by livestock and permitted use will be from 800 to 4,700 AUM's below livestock grazing capacity. The brush types created by fire or silvicultural manipulation will remain available to wildlife and livestock for up to 20 years on 75 percent of the suitable forage areas, particularly in decades 3 through 5. The drier vegetative zones may have some vegetative loss in the first few decades, but management of the vegetation will reverse this trend in later decades. Structural improvements such as fences and water developments will allow regulation of use in riparian zones and intensive grazing management systems will improve vegetative composition.

Alternatives C and F have 406,872 acres available to use for livestock grazing, and between 23,000 to 24,000 AUM's of permitted livestock use. All use will be within existing allotments. There will be 495,099 acres of suitable forage areas outside of existing allotments that will not be used by livestock. Between 14,700 and 15,500 AUM's of forage available for livestock use, and not needed for wildlife or other resource protection, will not be used. Brush types will grow out of reach in non-use areas within 5 to 10 years after timber harvest, but will remain usable for 20 years in existing allotments. A few of the lower elevation dry sites, where there is no current use by livestock, may continue to lose some vegetative cover. Utilization of riparian zones, and other natural animal concentration areas within allotments, will be regulated through intensive grazing systems and related structural improvements, which will maintain or improve plant composition and densities.

Alternatives E and G have 789,085 and 850,283 acres, respectively, available to use for livestock grazing, and there will be between 23,000 and 33,500 AUM's of permitted grazing use. These alternatives have a high number of acres of existing and potential forage and a moderate number of livestock to use as a management tool. There may be some loss of forage both through natural succession and lack of utilization. By the end of the fifth decade, there will be 65,000 acres of suitable forage that will not be used by live-

stock and permitted use will be from 5,300 to 6,900 AUM's below livestock grazing capacity. Forage created through fire and silvicultural practices may remain available to grazing animals for up to 20 years on 75 percent of the suitable grazing acres. In these two alternatives, some areas will not receive grazing treatment in the first few decades and low intensity treatment in decades three through five. The overall consequence will be some loss of available forage to animals, both wildlife and livestock, in 25 percent of the manipulated acreage. In these alternatives, as in the previous ones, the lower elevation dry sites will remain in intensive management or brought under more intensive management to improve vegetative cover. Riparian zones will be intensively managed through fencing, and use will be regulated to improve plant composition and densities.

4) Effects of Timber Management, Roads and Slash Disposal on Vegetation: Forage

Vegetative manipulation through logging with the related roading and slash reduction, provide transitory forage for big-game and livestock. Roading provides more opportunity for intensive management and dispersal of livestock, which offsets the loss of vegetation on the road surface. The effect of the additional forage results in greater grazing capacity for both wildlife and livestock in alternatives which have higher development and annual timber sale quantities. Alternatives J and NC have the most developed acres and the highest programmed timber sale offering Alternatives B, I and D are next followed by H, C and A/NFMA. Alternatives G, F and E will have the least development and smallest timber program, which will result in the least amount of forage for wildlife and livestock.

b. Cumulative Effects of Each Alternative

Although direct effects on vegetation, and subsequent indirect effects on other resources, are more readily apparent when vegetation is manipulated through silvicultural practices, manipulation of forage vegetation through grazing can contribute to effects on wildlife, soil, water, and fish. Forage can be increased or decreased by both use and lack of use. Losses in forage from total non-

use occurs through successional changes which are relatively slow, while seasonal non-use (intensive grazing) can improve density and composition of plants in just a few years. Heavy continuous use of forage by wildlife and/or livestock can speed up succession toward tree cover or reverse succession toward bare ground. If plant numbers are reduced over a large area or areas, there can be cumulative effects on other resources particularly livestock, wildlife, soil, water, and fish.

Effects such as those on stream habitat integrity, sediment yields, and competition for forage between wildlife and livestock are isolated and short term. They tend to be site specific rather than cumulative. In addition less than 20 percent of the total National Forest acres are available for use by livestock in any one decade. The acres suitable for livestock are widely dispersed through many separate watersheds, which reduces the chances of effects becoming cumulative. Many of the perceived effects of livestock on soils are actually visual effects resulting from trampling and utilization of vegetation.

Alternatives NC and A/NFMA may result in some cumulative effects in decades three through five. This would be due to the possibility of extensive continuous grazing without replacement of existing fences and water developments, which will become ineffective due to age. This loss of structural improvements and continued low level of administration may result in overutilization in riparian zones. When vegetative cover is lost along streambanks over a large area, increased sediment and degraded fish habitat may occur. Because livestock tend to congregate in this zone regardless of numbers, reducing livestock numbers will not be totally effective. In addition to the effects on soil, water, and fish, Alternative A/NFMA has only 18,800 acres allocated to key wildlife habitat management areas. Some cumulative effects may be expected on big game as more forage will be available to livestock on winter range areas. This effect will be even more likely to occur in Alternative H where only 17,000 acres are allocated to wildlife habitat management and livestock numbers will increase.

There are not expected to be any cumulative effects of Alternatives B, C, D, E, F, G, I and J on forage due to the following:

- (1) The effects described above will remain short term or site specific due to intensive grazing systems and higher levels of administration.
- (2) The forage base in all alternatives exceeds the projected levels of use.
- (3) The mitigation measures described below will help to avoid or reduce these effects.

c. Alternatives' Conflicts With Other Agency Plans and Policies

The Washington State Department of Wildlife developed a plan for managing Washington's wildlife through the year 1995. The Region III plan, which includes the Wenatchee National Forest, is completed. Based on information contained in the Region III plan, the forage base available for wildlife would be adequate in all alternatives to meet the Department of Wildlife's goals for wildlife.

All alternatives would have adequate vegetative forage resource to meet livestock and big game needs in any Coordinated Resource Management plans. These plans are a joint effort by the Washington State Department of Natural Resources, the U.S. Bureau of Land Management, and the U.S. Forest Service to coordinate management and use of all resources on an area which includes State and Federal ownership.

d. Mitigation Measures for Vegetation: Forage

There are several mitigation measures which are being implemented or will be implemented, to avoid or reduce the potential adverse impacts resulting from the utilization of the forage resource.

In development of the yields in animal unit months of grazing, an allowable utilization percent was used and adjusted to provide for plant needs and cover for soil and watershed protec-

tion. Some additional reductions in utilization were applied for other environmental factors, including fisheries, wildlife, recreation, and scenery.

The Standards and Guidelines which are part of the Forest Plan contain a listing of practices which include:

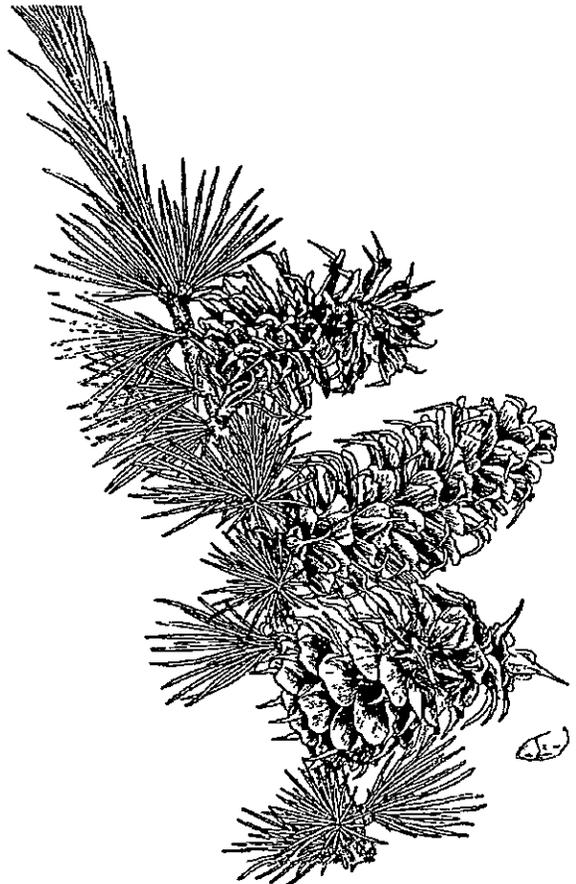

- (1) The grazing of suitable range through intensive systems will maximize the production of forage for wildlife in key wildlife areas, and for cover and watershed protection in the riparian protection zone.
- (2) Management systems will be designed to meet the highest prescribed levels of management when allotment boundaries cover more than one allocation area.
- (3) Utilization by livestock will follow established allowable use guides (see the Forest Plan), but may be adjusted to meet total resource needs.

Proper utilization and management of forage is the key to protection and enhancement of all resource values in the Forest environment. This has been studied and documented in numerous publications contained in the Journal of the Society for Range Management, and results have recently been documented in Forestland Grazing which are the proceedings of a Symposium held in 1983 at Spokane, Washington (a cooperative extension effort through Washington State University). The application of this management has been observed throughout the Forest on several range allotments. Where the integrity of a planned grazing management system is maintained through cooperation of the livestock owner, increased forage and ground cover has improved wildlife habitat as well as soil and watershed conditions.

The Forest will continue to do environmental analyses on existing range allotments in addition to new allotments and individual projects. These activities will be evaluated, using the Forest Plan Standards and Guidelines, for effects on the environment, and mitigation measures will be taken to reduce or avoid adverse impacts. The mitigation measures will include intensive man-

agement systems for controlling utilization. If the proposal would result in a significant unavoidable impact, it would be dropped or modified.

The effectiveness of the above mitigation measures may vary by alternative after the first decade. Generally the alternatives with the least amount of proposed permitted grazing use will respond more to the mitigation measures intended to reduce the adverse effects of grazing on the forage. However, because Alternatives NC and A/NFMA do not contain the funding levels to apply some of the mitigation measures, the above measures will be least effective in these two alternatives (see the discussion on NC and A/NFMA in Cumulative Effects on Vegetation: Forage). Permitted numbers will be the same in all alternatives during the first decade, so mitigation measures should respond equally for that period. After decade one, mitigation measures should produce the best results in Alternatives F, C and I, which allow the fewest number of permitted livestock. Alternatives E and G have the next fewest number of permitted livestock use. Mitigation measures may be least effective in Alternatives B, D, H and J due to the high level of permitted use in these alternatives.

**9(D) ENVIRONMENTAL
CONSEQUENCES OF THE ALTERNA-
TIVES ON UNIQUE ECOSYSTEMS**

**a. Direct and Indirect Effects of Each Alterna-
tive on Vegetation: Unique Ecosystems**

Unique ecosystems are areas that support or contain unique vegetative, ecologic or geologic attributes worthy of protection. The one existing area is the Tumwater Botanical Area on the Leavenworth Ranger District. This area is described in Chapter III.

The following 13 special interest areas are proposed for protection in some alternatives:

Camas Botanical Area - Located on the Leavenworth Ranger District in Section 32, T. 23 N., R. 18 E., and Section 4, T. 22 N., R. 18 E., this area is approximately 800 acres in size. Protection is proposed for Delphinium viridescens, Wenatchee Larkspur, which is one of two State and Federal candidates to the endangered species list.

Gene Creek Botanical Area - Located on the Entiat Ranger District in Sections 8, 17, and 20, T. 27 N., R. 20 E., this area is 1,930 acres in size. Protection is proposed for a ponderosa pine ecosystem containing old growth dependent animals and plants.

Hornet Ridge Botanical Area - Located on the Entiat Ranger District in Sections 4, 5, 6, and 10, T. 26 N., R. 19 E., this area is approximately 2,100 acres in size. Protection is proposed for the park-like stands of ponderosa pine containing old growth dependent animals and plants.

Lake Creek Botanical Area - Located on the Entiat Ranger District in Sections 27, 28, 33, and 34, T. 29 N., R. 19 E., this area is 212 acres in size. Protection is proposed for plants associated with an undisturbed wetland habitat.

Kloochman Rock Geologic Area - Located on the Naches Ranger District in Sections 4, 5, 8, and 9, T. 13 N., R. 14 E., this area is approximately 340 acres in size. Protection is proposed for a unique geologic feature.

Goose Egg Mountain Geologic Area - Located on the Naches Ranger District in Sections 31 and 32, T. 14 N., R. 14 E., and Sections 5 and 6, T. 13 N., R. 14 E., this area is approximately 635 acres in size. Protection is proposed for this unique geologic feature.

Rimrock Geologic Area - Located on the Naches Ranger District in Sections 25 and 36, T. 14 N., R. 13 E., and Sections 30 and 31, T. 14 N., R. 14 E., this area is approximately 425 acres in size. Protection is proposed for this unique geologic feature.

Blue Slide Geologic Area - Located on the Naches Ranger District in Sections 28, 29, 32, 33, and 34, T. 13 N., R. 13 E., and Section 4, T. 12 N., R. 13 E., this area is approximately 740 acres in size. Protection is proposed for this unique geologic feature.

Boulder Cave - Located on the Naches Ranger District in Section 16, T. 17 N., R. 14 E., this area is approximately 5 acres in size. Protection is proposed for this unique geologic feature and the habitat it provides for the Townsend's Big-eared bat.

Upper Naneum Meadows - Located on the Cle Elum Ranger District in Sections 1, 12 and 13, T. 21 N., R. 18 E. and Sections 7 and 18, T. 21 N., R. 19 E., this area is approximately 700 acres in size. Protection is proposed for the unique wet meadow ecosystems of this area.

Squaw Lake Area - Located on the Lake Wenatchee Ranger District in Sections 14, 15, 22 and 23, T. 27 N., R. 16 E., this area is approximately 200 acres in size. Protection is proposed for this area for its wetlands ecosystem, raptor nest habitat (bald eagle and osprey) and moose habitat.

Fish Lake Run - Located on the Lake Wenatchee Ranger District in Section 22, T. 27 N., R. 17 E., this area is approximately 150 acres in size. Protection is proposed because this is a critical riparian corridor that allows gene flow for the major riparian areas in the vicinity and also serves as unique wildlife habitat for Great Blue Heron, beaver and osprey.

Ponderosa Estates - Located on the Lake Wenatchee District in Section 24, T. 26 N., R. 17 E., this area is about 40 acres in size. Protection is proposed for this area because it is a unique transition zone between forest and non-forest and supports a number of unusual plant species including the sensitive species Cypripedium fasciculatum.

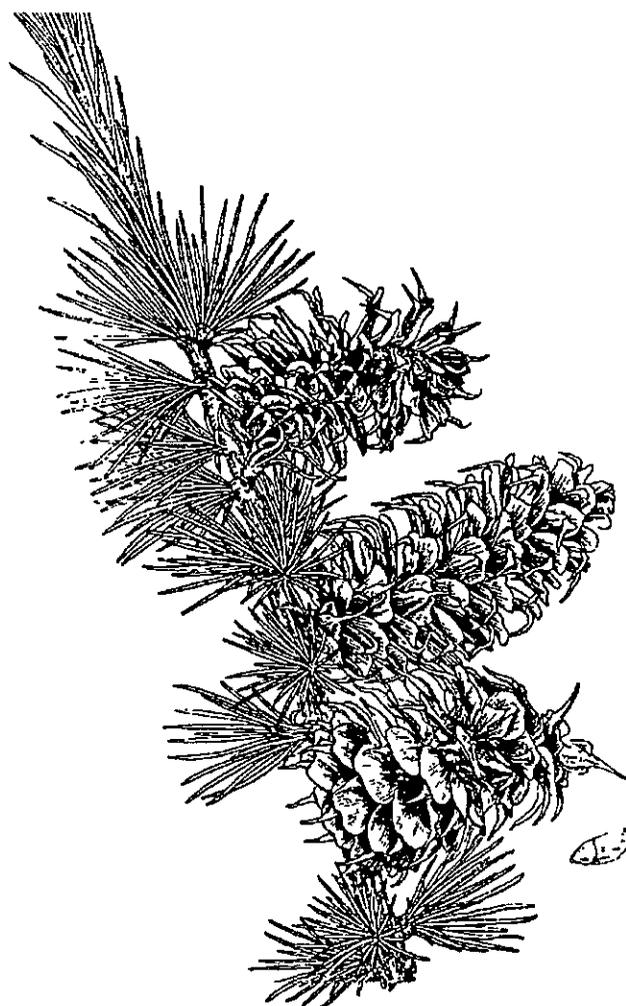

Many of the areas proposed are not subject to regular management activities regardless of the alternative. Five (Lake Creek, Camas, Upper Naneum, Squaw Lake, and Fish Lake Run) are wetland or riparian areas of noted value. Timber harvest and road building would likely avoid these areas. Five more areas (Kloochman Rock, Goose Egg, Rimrock, Blue Slide, and Boulder Cave) are being proposed for their geologic features. Many of these support little timber worth harvesting, are poor areas for locating new roads and the value for which the areas are being proposed are difficult to damage (geologic values). Some of the areas (especially Gene Creek and Hornet Ridge) do support significant merchantable timber. If not placed in a Special Interest Area prescription, these areas may be subject to timber harvest. However, Hornet Ridge may be protected by an Old Growth Forest prescription.

Mining activity, including mineral exploration, places all lands on the Forest in jeopardy at any time. This is true regardless of the alternative.

Designation of a unique ecosystem would definitely protect an area from management activities under normal circumstances. Grazing will not be allowed at all under the Special Interest Area (SI-2) designation. Any area that is not within a no-harvest prescription is subject to harvest and to some degree of risk. Generally only those attributes of an area that are vegetative or ecologic in nature can be significantly impacted by normal management activities.

In some alternatives, the above areas will be protected through allocation to the classified Special Interest management area when the adjacent management area is scheduled for vegetative manipulation. The areas may also be protected by unroaded allocations in some alternatives.

Table IV-17 shows the areas by alternative and under which alternative(s) they are proposed for protection. Areas showing an "X" in the table have a Special Interest area allocation, while areas showing an "A" are protected by an unroaded, non-vegetation manipulation prescription. In light of the above discussion, Table IV-17 provides an indication of the effects of the different alternatives on unique ecosystems and their inclusion into the Special Interest Area Management allocation. All alternatives contain the Tumwater Botanical Area under the Special Interest area allocation.

**TABLE IV-17
PROPOSED SPECIAL INTEREST AREAS BY ALTERNATIVE**

Upper Naneum Mdw				X		A					
Boulder Cave				X							
Squaw Lake Area				X							
Fish Lake Run				X							
Ponderosa Estates				X							

b. Cumulative Effects of Each Alternative

Each area is proposed due to its own unique feature. Not protecting the area may result in an effect on that feature, however, the effect would not be cumulative.

There are no cumulative effects of alternatives on Unique Ecosystems.

c. Alternatives' Conflicts with Other Agency Plans and Policies

There are no conflicts between the effects of the alternatives and other plans for Unique Ecosystems.

d. Mitigation Measures for Unique Ecosystems

The Standards and Guidelines which are part of the Forest Plan contain a listing of practices for the Unique Ecosystems which include:

- 1) Do not encourage recreation use and prohibit use if damaging to the area.
- 2) Fence as needed to exclude livestock.
- 3) No timber practice.
- 4) Exclude transportation and utility corridors.
- 5) Recommend withdrawal from mining and mineral leasing.
- 6) No roads will be constructed except reasonable access will be granted to landlocked inholders.
- 7) Use appropriate fire suppression strategy.

These measures should be equally effective in all alternatives in which the unique ecosystems are proposed for Special Interest Area designation

9(E) ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON VEGETATION: SENSITIVE PLANTS

a. Direct and Indirect Effects of Each Alternative on Vegetation: Sensitive Plants

Sensitive plants are protected by Forest Service policy under all alternatives. Biological evaluations are required for all ground-disturbing activities. These evaluations usually require on-the-ground surveys to locate sensitive plant species so that impacts can be avoided. However, as the number of ground-disturbing activities increase, the chance that a survey will miss a sensitive species increases, resulting in higher risk of unplanned impacts.

Effects of management activities on sensitive plants may also significantly affect biodiversity. Sensitive species are a component of biodiversity, and are limited in abundance and distribution. Consequently, the maintenance of sensitive plants is important to the maintenance of diversity.

1) Effects of Recreation on Vegetation: Sensitive Plants

Recreational use on the Wenatchee National Forest is ever increasing. Greater numbers of people on the landscape, and the development of campgrounds and access roads to accommodate the increase in numbers, will result in direct modification of the vegetation. This will produce greater risk of detrimental impacts to sensitive plants or their habitat.

Detrimental impacts to sensitive plants will result from trampling, compaction and vehicular use. Noxious weeds will increase because of both disturbance and introduction of weed seeds. Many of the impacts to sensitive species will be inadvertent. However, there probably will be deliberate collections by those who want either a live or pressed specimen for their personal use.

Forest-wide standards and guidelines for old growth and diversity, and policy for sensitive plants are designed to maintain adequate amounts of old growth and sensitive species for their own intrinsic values and as components of biological diversity. Increased recreational use will increase the risk of detrimental impacts to vegetation.

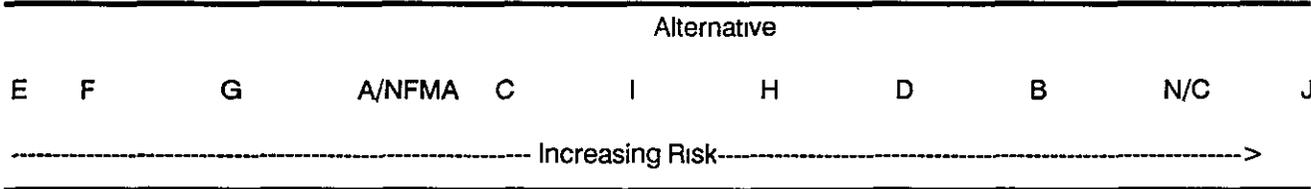

Semi-primitive recreation probably results in the least risk to sensitive plants, as impacts are fairly restricted in nature. As more land is allocated to developed and roaded recreation, however, the risk of substantive adverse impacts increases.

Alternatives with the most acres in non-motorized, semi-primitive allocations such as E (320,038 acres) and F (259,088 acres) would result in the least potential risk for adverse impacts to sensitive plants from recreation. Alternatives C and I (116,092 acres) and G (100,362 acres) would have somewhat greater risk of damage to sensitive plants than E and F, while alternatives with the least land allocated to semi-primitive, unroaded allocations (B, D, J, H, A/NFMA and NC) would have the greatest potential risk of adverse impacts to sensitive plants. Of all the alternatives, NC would pose the greatest risk because motorized recreational use is more widespread than in any other alternative.

2) Effects of Timber Management on Vegetation: Sensitive Plants

Please refer to the "Effects of Timber Management on Vegetation: Old Growth" for a general discussion of the types of activities related to timber management and the general effects that these activities have.

The predicted risk of impacts to sensitive species by alternative is shown below and reflects the effects of timber management, based on harvest levels.

3) Effects of Range Management on Vegetation: Sensitive Plants

It is difficult to assess the effects of the range management program on sensitive plants because so little is known about the ecological requirements of the species. Obviously, sensitive species that occupy springs and seeps where livestock come for water may be trampled out by the heavy use in the area. However, some sensitive species on the Forest appear to have undergone tremendous past livestock pressure and still survive. In fact, grazing may actually enhance some species. However, it is reasonable to assume that grazing, especially heavy grazing, is detrimental to most sensitive species. Extremely palatable sensitive species are searched out by livestock and may face adverse impacts from grazing. In the first two decades there is no significant difference between the alternatives. By the fifth decade, Alternatives B, D, E, G, H, I and J would have heavier grazing use than the other alternatives and consequently more damage to sensitive species would be expected in these alternatives.

4) Effects of Mineral Activity on Vegetation: Sensitive Plants

Like road construction, mining type activities often result in movement of earth and direct habitat modification that can be severe in nature. Those activities with the most influence on sensitive plants will be access road construction, mineral extraction and processing, waste disposal, increases in human use and reclamation activities. Generally, claimants holding a valid mining claim have a statutory right to mine, and this right *supersedes law and policy that protect vegetation from modification or destruction*. The extent of the effects of mineral activities on sensitive plants cannot be determined until the location, type and timing of the proposed activity is known. As a consequence, the specific effects that mining would have on vegetation resources and the differences in these effects by alternative cannot be estimated.

5) Effects of Roads on Vegetation: Sensitive Species

The increase in noxious weeds, increased access, changes in site hydrology and direct plant or habitat destruction are the greatest impacts of

roading to sensitive plant populations. Most of these effects cause vegetation change to some degree.

Although biological evaluations are completed for road right-of-ways, an increase in roading increases the risk of accidental destruction of sensitive species. These impacts would normally result from direct destruction of plants or their habitat or through changes in site hydrology. Indirect impacts of roads include an increase in habitat for pioneer species and for species that prefer ravelly type road-cut sites, including noxious weeds. Other indirect effects are increased access and traffic, leading to higher use levels and corridors for noxious weed increase.

The risk of impacts from roads in an alternative is directly related to the amount of roading. Alternative NC has the most roads followed by Alternatives J and B. These alternatives would have the highest risk of adverse impacts. Alternatives E and F construct the least number of new roads and have the least relative potential for adverse impacts. Table II-3a in Chapter II displays the miles of new road construction by alternative.

b. Cumulative Effects of Each Alternative

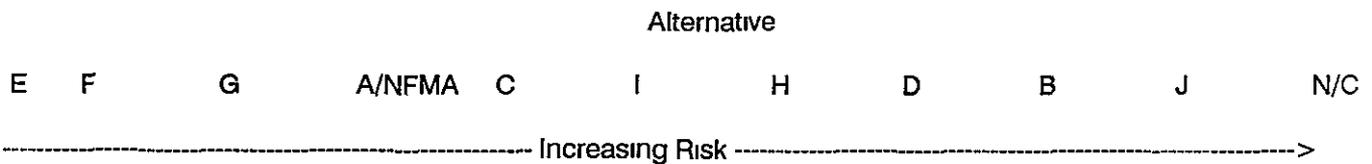

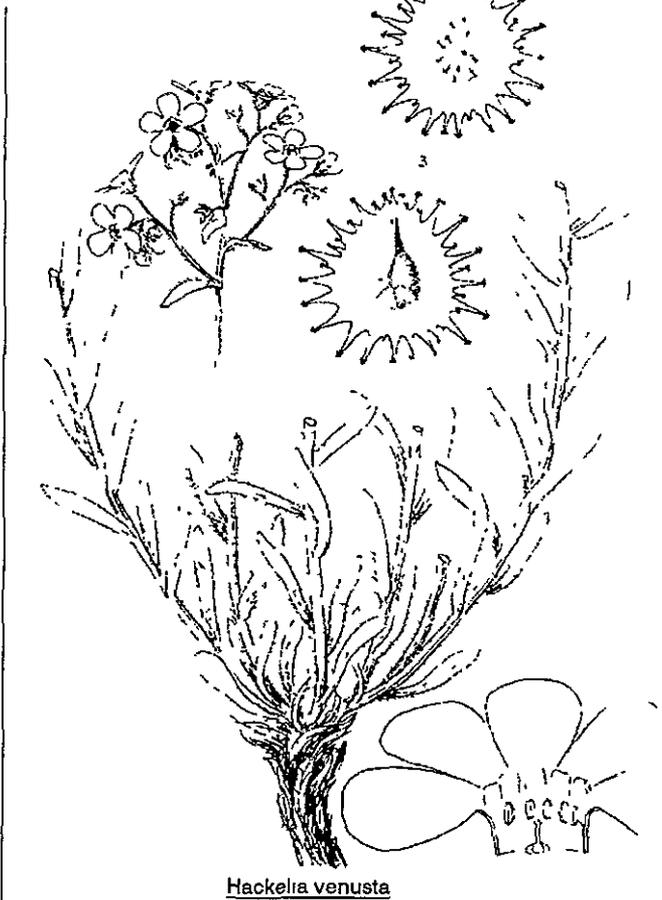

All alternatives will reduce the "natural" character of the vegetation through timber harvest, roading, recreational use and the myriad of other activities associated with the multiple use of National Forest System lands. The rate at which these modifications occur and the risk of error are what change by alternative. Cumulative effects are also the result of activities on lands owned by other parties. This section will discuss the effects of various activities on vegetation attributes regardless of ownership.

Currently, private and state owned lands reflect management activities that are highly commodity oriented. Consequently, in areas of intermixed ownership, the cumulative effects and risk of Forest Service alternatives that are also commodity oriented becomes very high. Forest Service lands become the critical links in the maintenance of sensitive plants.

Alternatives E, F, and G will have the greatest maintenance of the natural character of the landscape over time. Indirectly, however, the influence of insects, disease and fire may result in major cumulative effects on vegetation attributes, perhaps producing even greater cumulative effects than the more commodity oriented alternatives. With fire suppression activities, fuels will build up to unnatural levels, increasing the fire hazard. Higher than natural amounts of residue may also result in higher incidence of insects and disease. It will be very difficult to maintain the natural character of the stands over time, considering that the fire, insect and disease outbreaks will be the result of unnatural circumstances.

Rarer vegetation attributes like sensitive plants and old growth (and diversity of which these two attributes are a part) should (at least in the short term) be adequately maintained and/or the risk of error should be fairly low, since policy and law require their maintenance.

Considering all of the effects of activities on sensitive plants the predicted cumulative risk rating by alternative is shown below:

Alternatives A/NFMA, C, I and H will have intermediate levels of timber harvest and roading so that the cumulative effects of these types of activities should be more than in Alternatives E, F and G, but less than the high commodity Alternatives D, B and J. The indirect effects on vegetation attributes of increased fire intensity and insect and disease outbreaks in the mid-range alternatives should be somewhat less than in Alternatives E, F and G.

c. Alternatives' Conflicts with Other Agency Plans and Policies

No conflicts are anticipated between the effects of the alternatives and other agency plans and policies.

d. Mitigation Measures for Vegetation: Sensitive Plants

There are a number of mitigation measures incorporated into the Forest Plan for the maintenance of sensitive plants. Any mitigation measures in the Plan are applicable to all alternatives except NC. Measures required by law and policy are universally applicable. Mitigation measures applicable to all Forest Service activities are primarily addressed through land allocations, standards and guidelines and capital investments. Laws and Forest Service policy are also, to some extent, mitigation measures.

Generally, mitigation measures that are used for vegetative attributes of limited abundance such as sensitive plants (or old growth) are those that: 1. Avoid impact by not taking a certain action or parts of an action; 2. Minimize impacts by limiting the degree or magnitude of the action and its implementation or; 3. Reduce or eliminate the impact by preservation and maintenance operations during the life of the action. Repairing, rehabilitating or restoring the affected environment or compensating for the impact by replacing or providing substitute resources or environments are generally not effective means of mitigation for sensitive plants. Finally, Forest Service policy provides management requirements for the maintenance of sensitive plants.

9(F) ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON VEGETATION: RESEARCH NATURAL AREAS

a. Direct and Indirect Effects of Each Alternative on Vegetation: Research Natural Areas

Research Natural Areas (RNA's) are representative ecosystems where natural processes dominate. They are areas set aside for research, preservation of gene pools for sensitive plants and preservation of "typical" communities to serve as a baseline for management activities. Management is allowed only when needed to preserve the attributes for which the RNA was established. The two existing RNA's, Meeks Table and Thompson Clover, are described in Chapter III. Four new RNA's, in addition to the two already formally proposed, are listed in Table IV-18.

Alternatives B through G and I would recommend the establishment of four new Research Natural Areas. In addition, the two RNA's that are already formally proposed will remain in all alternatives.

Forest Service policy is to support the Research Natural Area program. Areas that fill needed cells in the system that are brought to the attention of the Forest by the Pacific Northwest Research Natural Area Committee are recommended for RNA designation. The Forest follows the recommendation of the Research Natural Area Committee.

Alternatives B through G fully support the maintenance of the RNA network on the Wenatchee as recommended by the Research Natural Area Committee. Alternatives N/C, A/NFMA, H and J only partially support the recommended RNA network, with four recommended areas not being proposed. For these four areas, the consequences are that vegetation manipulation (for any management purpose) or site destruction by roading may irreversibly preclude the selection of some of these areas for RNAs in the future. However, with our policy of supporting the RNA committee recommendations, further recommendation of potential RNAs would be ongoing and lead to amendment of the Forest Plan at any time to fill needed cells in the RNA system.

Alternatives that have greater amounts of ground-disturbing activities and vegetation manipulation may result in needed cells, whose existence are at this time unknown, being lost to management activity.

**TABLE IV-18
PROPOSED RESEARCH NATURAL AREAS BY ALTERNATIVE**

	ALTERNATIVES										
	N/C	A	B	C	D	E	F	G	H	I	J
1. Cedar Creek 1/			X	X	X	X	X	X		X	
2. Icicle/Frosty 1/			X	X	X	X	X	X		X	
3. Chiwaukum Creek 1/			X	X	X	X	X	X		X	
4. Drop Creek			X	X	X	X	X	X		X	
5. Fish Lake Bog 2/	X	X	X	X	X	X	X	X	X	X	X
6. El Dorado Creek 2/	X	X	X	X	X	X	X	X	X	X	X

1/ Within Wilderness
2/ Formally Proposed RNA

Three of the proposed RNA's are within wilderness. The effects of the alternatives would not vary in the wilderness and are not significant. Wilderness would have priority over non-manipulative research.

The proposed new RNA (Drop Creek) is located on Table Mountain. The effects of the alternatives on this proposed RNA would be related to the management area(s) that surround it as follows:

**TABLE IV-19
EFFECTS ON DROP CREEK PROPOSED RNA**

Alternative	ALTERNATIVES										
	N/C	A	B	C	D	E	F	G	H	I	J
Management Area(s) Bordering the RNA	N/A	N/A	RM-1	EW-1 ST-2	RM-1	ST-2	ST-2	EW-1 ST-2	N/A	EW-1 ST-2	N/A

N/A = Not Applicable

Alternatives A/NFMA, H, N/C and J would not make any new RNA proposals, and the Drop Creek Area would be designated as EW-1, Big Game Habitat. Alternatives C, G, and I have EW-1 (Deer and Elk Habitat) and ST-1 (Scenic Travel Retention) management areas adjacent to the RNA's. Both of these management areas allow timber harvest and livestock grazing but no harvest or grazing is allowed in the RNA. Alternatives B and D have RM-1 (Intensive Range) management areas adjacent to the RNA, however, grazing by livestock is not allowed in the RNA. The RE-2a (Unroaded Non-motorized)

management area in Alternatives E and F allow grazing also, but none will be allowed in the RNA's. The integrity of the new proposals for Research Natural Areas will be maintained in all alternatives except A/NFMA, H, N/C and J. That does not necessarily mean that these areas will be lost to the system. A later proposal by the Research Natural Committee or the Forest could result in these areas being proposed again in the selected alternative and the plan amended.

b. Cumulative Effects of Each Alternative

In every alternative, all RNAs are protected either by allocation as Research Natural Areas, or by their location within wilderness, with the exception of Drop Creek. The fact that Drop Creek, which is outside wilderness, is not protected in Alternatives NC, A/NFMA and H may result in a loss of the area as an RNA. However, the effect is direct and specific, not cumulative.

There are no cumulative effects of alternatives on Research Natural Areas.

c. Alternatives' Conflicts with Other Agency Plans and Policies

There are no conflicts between the effects of the alternatives and others' plans for Research Natural Areas. All alternatives contain areas formally proposed by the Research Natural Area Committee for the Pacific Northwest.

d. Mitigation Measures for Vegetation: Research Natural Areas

The Standards and Guidelines which are part of the Forest Plan contain a listing of practices which include:

- 1) Do not encourage recreation use and prohibit use if damaging to the area.
- 2) Fence as needed to exclude livestock.
- 3) No timber practice.
- 4) Exclude transportation and utility corridors.
- 5) Recommend withdrawal from mining and mineral leasing.
- 6) No roads will be constructed except reasonable access will be granted to landlocked in-holders.
- 7) Use appropriate fire suppression strategy.

These measures should be equally effective in all alternatives in which Research Natural Areas are proposed.

10. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON SOIL AND WATER

A primary objective of forest managers is to maintain soil productivity, water quality and the hydrologic balance of watershed systems. The intent of all alternatives is to manage watersheds to minimize the loss of soil productivity and to provide riparian area, stream channel and water quality conditions that would protect beneficial uses of water. Measures to achieve this intent, through preventive and mitigative measures, would be built into every alternative as Standards and Guidelines.

The following sections disclose the potential direct, indirect and cumulative effects of various allocations or management activities on soil and water resources. Descriptions are based on the analysis of those activities which have the greatest potential for effects on soil and water. Comparisons between alternatives are based on the relative amount of risk or benefit to soil and water resources from the management proposed in each alternative. Risk assessment is based on: (1) probable impact of implementation, including mitigation, (2) possible errors leading to inadequate project design, and (3) likelihood of administrative errors leading to inadequate implementation.

The cumulative effects section utilizes information from Tables F-1 through F-8 in the FEIS, Appendix F. These tables list the Forest's 25 major watersheds, providing information by alternative on the acreage in each watershed in private ownership, wilderness, National Forest lands subject to timber harvest, and unharvestable land. The cumulative effects section provides more information on long-term trends in watershed condition and a summary of the risk to soil and water resources for the various alternatives by watershed. A discussion of potential mitigation measures follows the narrative on the effects of alternatives.

Fish habitat is recognized as one of the most sensitive beneficial uses of water and as a primary indicator of watershed condition. The section in this chapter that discloses the effects of management activities on fish habitat compliments this soil and water narrative.

a. Direct and Indirect Effects of Each Alternative on Soil and Water

1) Effects of Developed Recreation on Soil and Water

The concentration of human activity at developed recreation facilities and their surrounding areas can adversely affect soil and water resources at these sites. Since most existing and potential developed sites are located within or adjacent to riparian areas, adverse impacts on riparian ecosystems and water quality can result.

Potential effects of developed recreation include total soil resource commitment to facilities, other reductions in soil productivity due to compaction, displacement, and erosion, increased sedimentation; reduced vegetative and other soil cover, collapsed stream banks and degraded shorelines. Microbial water pollution can occur from uncontrolled waste disposal. The potential for petroleum pollution also exists from use of vehicles and power boats. Some sites may show significant resource damage from a combination of overuse, improper camping techniques and insufficient maintenance. On a Forest-wide scale, these effects are localized and generally minor. Refer to the section on roads for a discussion of delivered sediment from recreation activities by alternative

Acres allocated to developed recreation provide an indication of the potential for impacts to soil and water resources from developed recreation. Alternatives E, H and A/NFMA would provide the lowest risk of adverse impacts to soil and water resources as a result of the lowest number of acres allocated to developed recreation (4,500 acres). Alternatives C and I would be next (6,000 acres), followed by Alternatives F (7,500 acres) and G (7,900 acres). Alternatives NC, B, D and J would provide the highest risk of adverse impacts to soil and water resources due to development and expansion of recreation facilities, with 8,200 to 8,500 acres in this allocation.

2) Effects of Dispersed Recreation on Soil and Water

Dispersed recreation decreases the risk of damage to soil and water resources from human-related causes compared to areas designated for developed recreation development. Effects of dispersed recreation activities on soil and water resources can include soil resource commitment, soil compaction, soil displacement, damage to vegetation, and increased erosion and sedimentation. Campsites and trails may show significant resource damage given a combination of overuse, improper camping techniques and insufficient control and maintenance, especially in riparian areas. The impact of horse and foot traffic in wet or other sensitive areas is common. Livestock usage and/or improper human sanitation can lead to increases in microbial contamination of streams and lakes.

Alternatives with the most acres in non-motorized, unroaded (semi-primitive) allocations, such as Alternative E (320,000 acres) and Alternative F (259,000 acres) would have the least potential for adverse impacts to soil and water resources from recreation. Alternatives C and I (116,092 acres) and G (100,362 acres) would provide appreciably more risk, followed by Alternatives B and D (84,400 acres), Alternative J (79,500 acres), Alternatives H and A/NFMA (59,500 acres) and Alternative NC (no acreage figures available). Alternative NC would pose the greatest risk because Forest-wide riparian standards would not apply.

3) Effects of Wild and Scenic River Recommendations on Soil and Water

Wild and Scenic River recommendation increases the probability that watershed conditions within study corridors would not be degraded during future planning. Natural riparian area and stream functions would receive the most protection under the development restrictions for the Wild River designation. These processes would receive somewhat less protection under the Scenic designation, with the Recreational designation allowing the most development

Wild and Scenic River designation would provide the most protection to fish habitat under Alternatives C, E, F, H and I as these alternatives allocate the most land to Wild, Scenic and Recreational River management and also have the most acreage managed as Wild River. Alternatives A/ NFMA and G allocate less land to Wild, Scenic, and Recreational River management, so they would provide somewhat less opportunity for protection of natural stream processes. Alternatives B, D, J and NC with no streams recommended would provide no additional protection to any streams.

4) Effects of Wildlife Habitat Improvement Projects on Soil and Water

The effects of planned ignitions for wildlife habitat improvement include stimulation of vegetative communities and reductions in catastrophic fire hazard. Burning for wildlife habitat improvement is addressed in the section on Fire Management effects.

Differences between alternatives for other wildlife related revegetation projects are not significant. The types of seeding/planting practices typically employed in revegetation projects for wildlife habitat improvement generally pose little risk of impacts to soil and water resources, while benefits occur from increases in soil cover.

5) Effects of Fish Habitat Improvement Projects on Soil and Water

The intent of the fish habitat improvement program is to improve riparian and in-stream habitat conditions. However, risk of damage to soil and water resources from fish habitat improvement projects exists for all alternatives. Damage to riparian areas and stream channels may result from administrative error and poorly planned or implemented projects in these sensitive locations.

Some fish habitat improvement projects would produce short-term localized increases in sediment. Certain practices may temporarily destabilize sections of stream channels. Improvements in streamside vegetation, pools and resting areas and the subsequent improved cover and reduced stream temperatures would provide long-term positive effects in the watershed.

6) Effects of Timber Management on Soil and Water

Timber harvest can have a significant effect on watershed conditions. The extent of the effect is dependent on the location, intensity and timing of harvest, and the specific methods of treatment. Effects can include commitment of the soil resource, other soil productivity reductions due to compaction, displacement, puddling, erosion and loss of nutrients, increased sedimentation, alteration of the water balance in cutover areas, and disturbance of riparian areas and stream channels.

There are many different soils on this Forest, with some being very sensitive to soil compaction. Still others may be sensitive to some other impact such as erosion, or displacement, etc. Some of the soils on the Forest are subject to mass failures, whereas others exhibit a high degree of stability. Soil types can change drastically within short distances, and it is important to determine soil conditions on a site-by-site basis.

Tractor logging costs are usually much lower than the costs for other kinds of systems, so they usually become the preferred system wherever possible. Tractor logging can cause unacceptable soil displacement, soil compaction, and puddling. Machine piling of logging slash can aggravate these effects to the soil resource. In addition, nutrients may be lost by removal of the surface layer (the "A" horizon), or by burning the organic residue in a very hot fire. Furthermore, tractor skid trails can cause runoff water to concentrate and increase in velocity, and thereby increase the risk of soil erosion if they are not properly treated.

Soil properties and characteristics can affect timber management activities. Some soils become slippery and sticky when wet, so they may affect the operating season or the choice of equipment, which then indirectly affects logging costs. Other soils are unstable and are subject to mass failures. These may affect the roadability or the cost of the operation. Some soils are easily compacted when the moisture conditions are just right, so they would affect the selection of equipment as well as the operating season. Some soils are excessively well drained and are well suited for winter logging because they resist compaction, are non-sticky or slippery, and often occur on gentle slopes.

Timber management activities most often have some degree of impact upon the soil resource. It is important to minimize the impacts whenever possible because most of the effects to soils are long-term. In addition, soil rehabilitation treatments for these effects are often very expensive and seldom are totally effective.

Timber harvest can cause potentially significant effects on stream channels. Changes in water yield, timing, and disturbance of the riparian vegetation can upset the dynamic equilibrium through which channel systems have evolved. Specific effects can include such factors as accelerated sedimentation, loss of streambank structure, alteration of water temperature, alteration of woody debris cycling, and spills of petroleum products. The potential impact on the channel network in subdrainages requires site specific analysis, especially when intermingled ownerships are involved (private lands, state land and other federal lands).

The following sections concentrate on the following factors in a comparison of the proposed alternatives: (1) areal extent and intensity of proposed treatment; (2) harvest in riparian management areas; and (3) potential changes in water yield. Refer to the section on roads for a discussion of delivered sediment from timber harvest and related road construction by alternative.

a. Areal Extent and Intensity of Proposed Treatment

The number of acres managed for timber production and the intensity of proposed management provide an indication of potential impact to soil and water resources. Higher risks are associated with those alternatives that require more acres allocated to intensive timber management.

Alternative NC would continue timber management activities as prescribed in the old timber management plans. Protection measures would include only those practices necessary to meet minimum conditions of the Washington State Forest Practice Rules. The Forest-wide Riparian Standards in the Plan are more restrictive than the State Forest Practice rules, but they would not

apply to this alternative. Therefore, Alternative NC would have the highest risk of not meeting watershed management objectives.

Out of the approximately 791,899 suitable acres available for timber management land allocations for the Forest Plan, Alternatives B and J harvest the most timber. They also have the most land allocated to General Forest (approximately 77 percent) and therefore exhibit a relatively high risk of adverse impacts to soil and water resources from timber harvest. Alternative D also has 77 percent of the land allocated to timber management, but the harvest rate is slower and therefore would have somewhat less risk than Alternatives B and J. Alternatives A/NFMA, C, H, and I have a relatively moderate risk of adverse impacts, with approximately 49 percent allocated to General Forest. Of these four, Alternative I would have somewhat higher risk because it is a departure alternative and would enter more acres in the first decade. Finally, Alternatives E, F, and G carry the least risk with 19 percent, 26 percent and 28 percent respectively of the available land allocated to timber production.

b. Harvest in Riparian Management Areas

Potential effects to riparian areas from timber management include soil productivity losses due to commitment of soil resource, compaction, displacement, erosion, increased sedimentation, damage to vegetation, disruption of debris cycling, changes in water temperature, disturbance of streambanks and chemical contamination. Harvest on these acres may have beneficial effects on riparian succession when conducted to reduce excessive fuel loading resulting from long-term fire suppression or to meet other watershed or fish habitat objectives.

The number of acres in the riparian prescription (EW-2) provides an indication of the potential for direct impacts to soil and water resources in these sensitive areas. Alternatives E and F would pose the least risk of damage to soil and water resources from timber management activities, with 38,012 and 40,832 acres allocated to the riparian prescription. Alternative G would be next since it allocates 47,573 acres to the prescription and contains less risk of management conflicts result-

ing from harvest in adjacent upland areas due to the lower yield. Alternatives C and I would be next (47,361 acres), but with Alternative I having a higher risk due to the management intensity of this departure alternative. Alternatives H (52,301), J (52,470 acres) and A/NFMA (53,849 acres) would be next, with Alternatives D and B (58,046) posing the most risk to soil and water resources due to timber harvest activities within riparian areas.

Timber harvest in stands adjacent to riparian areas pose a risk to soil and water resources within these zones. For example, blowdown potential may increase in shallow-rooted riparian stands if large openings are created in adjacent areas. The desire to treat potential insect and disease sources in riparian stands would increase proportionally to the management intensity on adjacent lands. The risks associated with these kinds of potential conflicts are proportional to the increase in treated acres by alternative.

c. Potential Changes in Water Yield

The primary source of streamflow on the east side of the Cascades is the winter snowpack. Streamflow is characterized by great seasonal fluctuations, being abundant and flashy in the spring and diminishing rapidly to near base flow levels during the summer. Water yield management is, therefore, related to management of the snowpack (USFS, 1978).

Numerous research and administrative studies have been completed on small watersheds (generally less than 100 acres) in which streamflow has been evaluated both before and after timber harvest. The general conclusion is that temporary on-site increases in annual and summer flows normally occur. Increases in annual and low flows are greatest in moist environments and least in arid areas. When the extra water contributed from newly harvested areas is added to the vast areas yielding water at background level, the increase in water yield becomes insignificant. While initial on-site increases may be substantial, they are generally too small (less than 5 percent) to be measureable in larger watersheds downstream, where only one to two percent of the area is harvested annually. This is due to vegetation regrowth in harvested areas.

The magnitude of the increase depends on a number of factors including the vegetation type, total area harvested, the silvicultural treatment applied (e.g., percent of crown removed), soils, geology, topography and climatic factors. Water yield can generally be expected to increase proportionally with increases in the area logged or crown removed. Increases are due mainly to reduced interception, decreased evapotranspiration, increased snow accumulations on cutover areas, and more efficient conversion of the snowpack to streamflow. The magnitude and duration of these increases in discharge, which generally occur during spring runoff, may affect the stability and integrity of stream channels.

Research has shown that water yield increases from timber harvest may persist from 5 to 30 or more years. However, the magnitude of the water yield increase from a cutover area is gradually diminished each year as revegetation occurs, eventually returning to preharvest levels.

A positive result of timber harvest is the increase in stream flow during the critical summer months. Although the increased flow in the summer period is small, the greatest percentage increase occurs during the summer. Current research suggests that the duration of increase for low summer stream flows is shorter, perhaps only five years, even though the increase in total annual yield may persist for up to 25 years or longer. Actual realization of this increase may be affected by downstream masking of flows as well as management practices downstream that degrade riparian conditions and lower water tables.

Research also indicates that the effects of timber harvest on peak flows are inconclusive. Even though peak flows may be increased by harvest on the immediate small watershed, this effect is rapidly diminished downstream as the flows of many tributaries combine with the main stream (Bethlahmy, 1972). Maximum floods on the main stream result from the synchronization of the flood peaks from its tributaries. Therefore, partial clearcutting of a watershed may reduce the magnitude of peaks when snowmelt from clearcut areas is not synchronized with slower melt from forested tributaries of the watershed. Conversely, the opposite may occur if synchronization is

enhanced. Sufficient knowledge is presently available to make it possible to cut timber with no aggravation of peak flows or possibly a reduction of peak flows. This may be accomplished by designing the timber harvesting program (area, size, aspect, elevation, etc.) to maximize the diversity of snowmelt on the various components of a watershed, and to reduce the chance of synchronized peak flows from tributaries of the watershed (USDA, 1978).

When soils are saturated, the magnitude of larger peak flows will normally be similar with or without timber harvest and roads (Wright, 1985). However, in the less frequent "rain-on-snow" events, harvested areas may contribute to increased peaks. A major storm event, coupled with a heavy snowpack at the mid to lower elevations, may produce higher peak flows which increase the potential for both hillslope and channel erosion. The drainage size will normally influence and normalize the peak flows to the extent that downstream values and structures are not placed at risk.

The potential increases in annual water yield over existing yields by alternative are shown in Chapter II in Table II-3a. These values are intended to be used for relative comparison between alternatives and should not be taken as absolute numbers. All alternatives would increase water yield over existing conditions at varying amounts that reflect differing harvest levels.

The magnitude of estimated yield increases provides an indication of the potential for the occurrence of adverse impacts to soil and water resources. Over the first five decades, Alternative J would pose the most risk, followed by Alternative B and NC. Alternatives H, D, C, I, and A/NFMA would pose moderate levels of risk. Alternatives G, F and E would pose the least risk of adverse impacts to soil and water resources due to alterations in water yield.

In all alternatives, the magnitude of the increase would fluctuate significantly from year to year due to natural conditions. When the annual yield increase by alternative is compared to the Forest's annual background runoff, the increase appears insignificant because it is "masked" by the large annual runoff figure. The additional water pro-

duced by the removal of forest vegetation during timber harvest for all alternatives varies less than 1 percent when compared to the Forest's background annual runoff of 4,455,000 acre feet. Therefore, the consequences of increased water yield need to be evaluated on a watershed basis. In a small watershed heavily impacted by timber harvest, stream channel erosion and degradation could occur. On a site-specific basis, potential increases in water yield will probably not affect stream channel morphology as long as timber harvests are not concentrated in any one drainage over time and space.

Public concern exists for the potential for the cumulative effect of management activities on water yield from several standpoints, such as: (1) quantity of flow available through augmentation and storage, (2) channel stability impacts from variations in peakflows, (3) maintenance of low flows for channel maintenance and fish habitat, and (4) maintenance of low flows for irrigation. These issues are affected by a large number of interrelated factors such as annual and long-term trends in precipitation, evapotranspiration, groundwater movement, stream channel and riparian conditions, irrigation withdrawals, storage facilities, land use practices and water conservation efforts.

Protection of water resources is a primary responsibility of the USDA Forest Service. In this regard, maintenance of water quality and a favorable streamflow regime are high priority goals. Direct augmentation of streamflows is not a primary goal of the Forest Service. Increases in water quantity may result from some forest management activities; however, concern over the protection of water quality and streamflow regime would be paramount. The Forest Service is only one of the many organizations involved in water yield management. The Forest will fulfill its role in this effort through more site specific analysis of the cumulative effects issue at the project level. However, the responsibility for basin-wide management of the water resource is shared by all landowners.

7) Effects of Range Management on Soil and Water

The effects of grazing depend on the intensity, duration and season of use and on soil and site sensitivity. The two categories of effects include: (1) the effects of the animals (both wildlife and domestic stock) as they graze, and (2) the effects of the structural and nonstructural improvements constructed to manage livestock.

Grazing animals consume varying amounts of water and vegetation (grasses, forbs, and shrubs), and alter plant communities. Soil displacement and compaction combined with a reduction in ground cover can create bare soil areas. Effects of grazing may be localized, such as compaction around water developments, salt licks, major travel routes, and along fences. More widespread effects are evident from concentrations of animals in dry meadows, riparian areas, and other favorable sites near water and shade.

Some site-specific impacts to riparian management areas from grazing would occur under all alternatives. Heavy grazing in riparian areas can reduce or modify plant species composition, structure, abundance, and plant vigor. Soils in riparian areas open to grazing are especially susceptible to puddling, compaction and erosion due to livestock concentrations. Alteration of channel morphology (width/depth) results from trampling and bank cave-ins as stock seek access to and across streams. Additional effects include increased sedimentation, a decrease in stream-bank habitat, reduced streamside cover and shading, altered stream temperatures, nutrient loading and microbial pollution. These effects can be lessened by mitigation identified through increased administration and coordination with other resources.

Structural range improvements include construction of fences, water developments, corrals and cattleguards. These activities have local, site-specific effects on soil physical properties and conditions (compaction, displacement, erosion). A total soil resource commitment is made in areas such as corrals and water developments.

Nonstructural range improvements include grass seeding, fertilizing, discing, burning, and noxious weed control. Nonstructural activities can affect soil physical, chemical and biological properties. Minor and temporary effects would occur under all alternatives. Exposure of bare soil for short periods of time would cause some soil loss. If intense rainstorms occur at this time, soil erosion would occur. Successful treatment, however, allows grasses and other vegetation to rapidly occupy the sites and mitigate impacts to soil and water resources.

Under all alternatives, permitted use in the first decade would remain at the present level (23,000 AUM's). Beyond the first decade, Alternatives A/NFMA and NC include progressive reductions in expected grazing use. Alternative NC would not meet legal requirements since, for example, standards designed to protect riparian habitat are not included in the alternative. Reductions in use in Alternative A/NFMA may result in improvements in watershed condition in some areas, however, lack of control due to loss of fences after the second decade may result in increased compaction and puddling of soils.

Alternatives B, D, E, G, H, I and J would allow an increase in grazing over more acres, between approximately 400,000 and 450,000 acres. These alternatives would increase the risk of impacts to soil and water resources, but due to increased range administration funds needed for implementation, these alternatives may actually be less risky than Alternative A/NFMA.

Alternatives C and F pose the least risk of impacts to soil and water resources, as the number of acres allocated to grazing would remain the same as the current situation. There would also be little or no increase in permitted use over the life of the Plan.

All alternatives contain risk of damage to riparian management areas and other concentration sites from dispersed recreation use, especially from private and commercial stock use.

8) Effects of Forest Pest Management on Soil and Water

Alternatives rank the same as discussed under the effects of fire, timber, and range management for the effects of forest pest management. Increased livestock grazing or timber management might lead to increased need for pest control measures. Decreases in acres of prescribed fire may lead to increases in the need for pest control measures.

The physical, chemical and biological measures used in Forest pest management have a wide range of effects. The effects of timber harvest (salvage) are addressed under the section on timber management. The use of chemical biocides can have both direct and indirect effects such as direct toxicity on non-target species and bioaccumulation, including the potential degradation of domestic water supplies. Biological control measures pose the least risk of damage to soil and water resources.

9) Effects of Watershed Improvement Projects on Soil and Water

Watershed improvement projects have as their objective the improvement of long-term watershed condition. These projects consist of treatments such as site revegetation, obliteration of non-system roads and stabilization of gullies and streambanks. Projects involve relatively small acreages or stream reaches, but may result in the improvement of conditions in a larger portion of the watershed and its stream system. Productivity losses from other Forest management activities may be partially offset by watershed improvement projects in localized areas.

Short-term soil disturbance is associated with most projects and some minor sediment increases may occur, especially with some stream-related improvement projects. Some risks of damage to riparian areas and stream channels exist as a result of administrative error and poorly planned or implemented projects in these sensitive locations. However, the long-term effects on soil productivity and beneficial uses are positive.

10) Effects of Mineral Activities on Soil and Water

The amount of mining activity on the Forest is more a reflection of metal prices than activities scheduled by the Forest. Effects of mining on soil and water resources vary only slightly by alternative, primarily based on changes in access, which are addressed in the section on roads. Other effects of mining on soil and water are assumed to be constant by alternative.

Exploration for and development of mineral, non-mineral, and energy resources affect soil and water resources. Activities that can occur include construction of roads and trails, pipelines, ditches, drill pads, water impoundments, adits and shafts, and various buildings and support facilities.

Potential effects of mining include: total soil resource commitment to facilities, other soil productivity losses due to compaction, displacement and erosion, increased sedimentation, removal of vegetative cover, riparian area and stream channel alterations, streamflow diversion, thermal changes and chemical pollution from leaching or spills.

The magnitude, extent, and duration of the effects are project dependent. The effects of mining activities cannot be anticipated until specific proposals are submitted. Each proposal will be analyzed with respect to existing mining and environmental laws at the time of submission. Operating plans would include provisions to minimize detrimental impacts on watershed conditions and water quality. In relative terms, the potential for mining to cause adverse impacts on soil and water resources is inversely proportional to the amount of area managed as roadless or under highly restrictive management strategies. Refer to the minerals section of Chapter IV for further details.

11) Effects of Special Use Activities on Soil and Water

The effects of special use activities vary only slightly by alternative. This variation is primarily related to increased access which is addressed in the section on roads.

Special use activities that have the potential to affect soil and water resources include cabins, group camps, roads for access to mining claims and private lands, water developments (such as dams, diversions and hydropower projects), utility corridors, and outfitting and guiding operations.

Access roads have both short and long-term impacts on the soil and water resource as discussed in the section on roads.

Effects of water-related developments may include total commitment of the soil resource for facilities, increases in erosion, modification of riparian areas and stream channels, and the interactive effects of increased sedimentation and altered flow regimes.

Construction and maintenance of utility corridors involve roading and other disturbances that may affect soil productivity, increase erosion/sedimentation and disturb riparian areas. Outfitting and guiding operations may damage upland and riparian areas at camps and other sites where use is concentrated.

Although the effects of special uses can be significant for a specific site, individually these uses are generally limited to small acreages on the Forest. Collectively, special uses affect a significant acreage of land on the Forest. The magnitude, extent and duration of the effects are dependent on the type and amount of use, and cannot be anticipated until proposals are submitted. Each proposal will be analyzed with respect to Standards and Guidelines and other direction to minimize the potential for adverse impacts.

12) Effects of Roads on Soil and Water

Roads can have a significant effect on soil and water resources and are probably the greatest potential sediment source of all land management activities. Potential effects of road construction/reconstruction and maintenance include total commitment of the soil resource, alteration of the runoff characteristics of the slope, increases in sedimentation from accelerated surface and mass erosion, reduction in soil productivity (compaction, puddling, displacement), and disturbance of riparian areas and stream channels.

It is well documented in the scientific literature that the largest amounts of activity-related sediment in streams are the result of road construction. The largest increases in sediment production occur during the first two years following construction, with the magnitude of the increase diminishing over time, depending on road use and management.

Impacts associated with reconstruction of existing roads from prior entries should be significantly less than those associated with new construction. Risk of damage to soil and water resources should be lower in those alternatives that emphasize reconstruction and use of well-located existing roads to achieve market outputs.

a. Sediment Yield

Sediment yield (amount of eroded soil material that enters a live stream or lake) varies depending on many different factors such as: erosiveness of the local soil material, amount of exposed (bare) mineral surface soil, infiltration capacity of the soil surface, steepness of slope, length of individual slopes, distance from the stream or lake, roughness coefficient, and storm intensity. The kind of activity that takes place on the land can also have a major effect, because of the amount of land that the activity takes place on.

Road construction and reconstruction have the greatest potential, on an acre by acre basis, of producing the most delivered sediment. This is because these activities are designed to move large amounts of soil from one place to another. Having the road properly located to avoid particularly hazardous areas, using good road design to provide adequate water control measures, and using mitigation measures such as grass seeding cut and fill slopes, can all reduce the amount of delivered sediment that is produced. Road surfaces can also be a major source of sediment which should be considered when designing erosion control measures.

Timber management activities include many different kinds of logging systems, such as tractors, cable, helicopter, etc. Each has its own unique characteristics that affect how much or how little soil displacement takes place (from both road construction and yarding of logs).

Another common problem associated with these activities is slash disposal. Machine piling, broadcast burning, leaving the slash in place, or "lop and scatter" are commonly accepted disposal practices. Each method can affect how much soil displacement or compaction may or may not take place. Delivered sediment, therefore, is dependent on many variables related to the kind and timing of management practices that are applied to the lands that lie above the streams and lakes.

Sediment yields vary by alternative because of differences in management objectives. The management activities that have been used for modeling are the road construction/reconstruction activities and the timber harvesting systems. Because of this, alternatives that build more roads and harvest more timber also produce more delivered sediment. The assumption was made that the number of other sediment producing activities either are not well defined (e.g. mining), produce too little sediment to be concerned about in a Forest-wide analysis, or else the activities that produce it are the same for all alternatives, e.g., developed recreation sites. Refer to Chapter II for the quantities of delivered sediment produced by the different alternatives.

b. Road Construction - Total Proposed

The major changes in watershed condition would occur during the first three decades when most new road construction would take place. The miles of road construction provide an indication of potential impact to soil and water resources. Higher risks are associated with those alternatives that require more new road construction to achieve market outputs. The risk of road-related conflicts in riparian areas may also increase proportionally to the amount of new road constructed by alternative.

Other than Alternative NC, Alternatives J and B construct the most roads and therefore have the greatest potential risk of adverse impacts. Alternatives E and F construct the least amount of new roads and have the least potential for impact. Refer to Table II-3a in Chapter II for a display of new road construction by alternative.

c. Road Construction - Within Roadless Areas Only

Road construction in unroaded areas introduces the area to a wide range of new resource risks. Road construction, maintenance, and use may significantly affect watershed condition. This is dependent on the location, extent, and intensity of new roading and associated activities, and the management controls applied to the new system.

As noted in the previous section, miles of new road construction provide an indication of potential impact to soil and water resources. Higher risks are associated with those alternatives that require more new road construction to achieve market outputs. The risk of road-related conflicts in riparian areas increases proportionally to the amount of road constructed by alternative.

Alternatives E and F would pose the least risk of damage to soil and water resources from new road construction in roadless areas, with only 180 and 222 miles proposed during the first three decades, respectively. Alternative G (458 miles) is next, followed by Alternatives H (652 miles), C (706 miles), I (713 miles), A/NFMA (748 miles), and D (853 miles). Alternatives B (979 miles) and J (1,006 miles) would pose the highest risk of damage to soil and water resources from new road construction on the Forest.

d. Road Maintenance

The effects of road maintenance are the same for all alternatives, the only difference being the variation in the number of miles requiring maintenance. Alternatives with higher timber harvest (such as Alternatives B and J) would have correspondingly higher amounts of road maintenance performed by timber purchasers rather than Forest crews. The risk of damage to soil and water resources from poor maintenance practices is proportional to the levels of new road construction, which has already been addressed. The future shift from direct maintenance to more emphasis on access management, such as restrictions and closures, should have mitigative benefits for soil and water resources.

e. Management of New Roads

Benefits to soil and water resources from access management occur in alternatives that emphasize access restrictions or closures. These management options can significantly reduce erosion and sedimentation from roadways, as well as reducing maintenance costs. Traffic management can also significantly reduce the potential for damage to facilities and adjacent areas by off-highway vehicles (OHVs).

The proposed new road closure policy provides an indication of the potential benefits to soil and water resources between the alternatives. Alternatives C, D, E, and J provide the most potential benefits due to a 100% closure policy on all new roads. Alternatives F (90%), A/NFMA (80%), and G (70%) provide progressively less benefit. Alternatives I (25%) and H (20%) provide substantially fewer benefits, followed by Alternative B (0%) which would not close any new roads.

13) Effects of Fire Management on Soil and Water

Impacts from burns vary widely, depending on fire type, timing, extent, intensity and location. Prescribed fires for natural fuels reduction and range and wildlife improvement typically occur in the spring. High soil and litter moisture levels at this time of year generally result in cool burns with low potential for significant erosion and sedimentation.

Planned ignitions in the fall have a higher risk due to lower soil moistures. The amount of soil loss from wildfires is primarily dependent on the fire intensity and soil type on which the fire occurred. Runoff from burned areas may result in lower water quality for short periods of time, with the greatest risk associated with large, high intensity wildfires.

Planned ignitions benefit watershed condition by reducing the risk of catastrophic wildfire and promoting more natural ecosystem function. The effects of high intensity burns (hot burns) include such things as: changes in soil physical and chemical properties (nutrient loss, loss of micro-organisms, altered infiltration rates, erosion, and

sedimentation), alteration of water yields (volume and timing), and thermal changes in the watershed (soil and stream temperatures).

High soil temperatures from hot burns can have an effect upon the soil resource. Not only can it destroy micro-organisms in the soil, but it may also volatilize some of the nutrients. Machine piling slash can be particularly damaging, because it can cause soil displacement, soil compaction, and puddling. Broadcast burning is less likely to damage the soil than is machine piling. Most prescribed burning is tied to timber harvest activities, so the possible impact to the soil resources will generally be tied to these same general areas.

Those alternatives with the lowest potential for high intensity wildfires have the lowest potential for adverse effects from wildfire suppression activities. Potential effects of fire suppression activities include increased erosion and sedimentation from fireline construction, direct damage to riparian areas, and potential for spills (e.g., petroleum products, retardant). Under all alternatives, appropriate burn rehabilitation measures would be implemented following major wildfires to minimize adverse on-site and off-site impacts to soil and water resources.

14) Effects of Other Forest Management Activities on Soil and Water

Other factors affecting soil and water resources are constant or nearly constant among alternatives. Management of water rights on the Forest, administrative site management, special area designations, such as wilderness and Research Natural Areas, and special uses other than those discussed above are assumed to be similar between alternatives. These activities are covered by Standards and Guidelines which should be similarly effective in all alternatives.

The effects of these and other activities discussed in this section are considered in the following section on cumulative effects.

b. Cumulative Effects of Each Alternative

This analysis considers the potential for cumulative effects of management activities on soil and water resources only.

Cumulative effects are the result of the combined effects of individual management activities on all lands within a watershed. This could be for areas that are completely in Federal ownership, as well as for areas with intermingled ownerships (areas that include both National Forest and other ownerships). Other ownership includes lands controlled by other federal agencies, the state, private landowners and Indian tribes.

Cumulative effects can be negative, neutral, or positive depending upon the net results of the applied activities. Changes that occur as a result of management activities can be the result of one or more repetitions of one specific activity, or the combined effect of several different activities or factors.

Reduction of soil productivity and/or degradation of water quality are cumulative effects of primary concern to the forest manager. Some of the specific effects that may be generated and interact in a cumulative fashion are identified below. For a more complete discussion of the specific effects of various allocations and management activities on soil and water resources, refer to the Direct and Indirect Effects sections in this chapter for Soil and Water and for Fisheries.

Soil Resources

Soil productivity can be changed (lowered), by both physical and chemical processes. Specific soil changes that usually reduce soil productivity include: soil compaction (change in soil structure, increased bulk density, reduced pore space, and resistance to root development), puddling (change in soil structure, reduced infiltration rate, and reduced root penetration), soil erosion (loss of nutrients, and reduced water holding capacity - soil depth); soil displacement (removal of the A horizon - loss of organic matter and nutrients); volatilization (loss of nutrients and organic matter), and nutrient cycling (loss of nutrients).

Water Resources

Water quality, quantity and associated values (e.g., fish habitat) can be altered by physical, chemical and biological processes. Specific effects on the water resource due to management activities may include: accelerated sedimentation (e.g., increased turbidity, increased suspended sediment concentrations, increased bedload sediment transport, increased sediment deposition in fish habitat); alteration of stream temperatures (e.g., summer stream temperature increases, winter temperature decreases); changes in fine and large organic matter input to stream channels (e.g., alteration of food supplies, and changes in stream energy dissipation patterns); alteration of streamflow regimes (e.g., increased peak flows, increased low flows, and changes in timing); disruption of hillslope hydrology (e.g., changes in water tables, interception of subsurface flows).

Individually, changes in any of these factors can reduce soil productivity or alter water quality, respectively; however, in most forest situations, these processes seldom occur by themselves. Instead, several processes and associated effects may be occurring at the same time within any specific activity area.

Analysis Approach

Current state-of-the-art environmental analysis does not permit a reliable prediction and quantification of the impacts of all activities that can potentially affect soil and water resources. Quantification techniques are available for individual factors, such as sediment yield or water temperature, for use where select parameters are of primary concern. However, evaluation of how several parameters or activities might interact in a cumulative manner is still largely a task of professional judgement.

A risk factor approach was used to evaluate the potential cumulative effects of the proposed alternatives on soil and water resources. This approach was taken because available methodologies, which produce a single quantitative index, do not adequately portray the effects of multiple management activities across the entire Forest.

This is due to the complex and diverse nature of watersheds, and to the variations in the intensity, patterns, and types of land uses on the Forest.

This analysis is based on the premise that land disturbing, management activities can have an effect upon watershed values, specifically soil productivity, slope hydrology, water quality and fish habitat. Furthermore, it can generally be assumed that the more activities that take place in an area (e.g., acres of timber harvested, miles of road built, etc.), the greater will be the risk of watershed degradation.

The analysis process includes all lands (federal, state, and private) inside the National Forest protection boundary, including both wilderness and non-wilderness areas, that lie within each of the 25 watersheds identified on the Forest (see FEIS, Appendix F). Some of the watersheds are located entirely within the National Forest protection boundary. However, most watersheds extend beyond the Forest boundary. The Forest Plan can only address the use and management of the land administered by the Forest Service, but it must also consider the use and management of all lands within the Forest protection boundary, both National Forest and other owners. Portions of watersheds downstream from the Forest protection boundary are not considered in this analysis.

The potential for cumulative effects on soil and water resources has been grouped into three broad risk categories: high, moderate, and low. This rating considers both the long-term risk of on-site soil productivity losses as well as the risk of downstream impacts to channel condition, water quality and capital investments. For purposes of this analysis, it will be assumed that all other ownership lands within the Forest protection boundary will be managed for intensive timber management. The risk categories are defined as follows: "High" refers to watersheds that have fifty percent or more of the land being managed for intensive timber management over the long term; "Moderate" refers to watersheds that have twenty-six to forty-nine percent of the land being managed for intensive timber management; and "Low" refers to watersheds that have twenty-five percent or less of the land being managed for intensive timber management.

Refer to the tables in FEIS, Appendix F for details on the ownership and allocations in the 25 watersheds in this analysis.

Watershed Analysis

Eight of the watersheds (Nason Creek, White/Little Wenatchee, Bumping River, Teanaway, Cle Elum, American River, Icicle River, and Stehekin River) have low percentages of the land allocated to intensive timber management activities. Consequently the risk for cumulative effects on soil and water resources in these watersheds in all alternatives will be low. Even though the overall rating for these watersheds is low, there could be individual subdrainages within some of the watersheds that could have a moderate or high risk for cumulative effects. Site specific determinations will be made on a project basis.

Five watersheds (Upper Tieton, Peshastin Creek, Chiwawa Creek, Lake Chelan, and Rattlesnake Creek) have low and moderate risk ratings for cumulative effects from management activities on soil and water resources. Alternatives E, F, and G all have a low risk (twenty-five percent or less of the land allocated to intensive timber management) for cumulative effects for the above named watersheds. Except for Peshastin Creek, these watersheds also have a low risk rating for cumulative effects for Alternatives A/NFMA, C, H, and I. Peshastin Creek has a moderate risk for these same alternatives. All of the five watersheds have a moderate risk for cumulative effects with Alternatives B and D. All of the watersheds, except the Rattlesnake watershed, have a moderate risk associated with Alternative J. Alternative J poses a low risk for cumulative effects in the Rattlesnake watershed. However, within any of these watersheds, there could be specific subdrainages that could have a high risk for cumulative effects. Site specific determinations will be made on a project basis.

Of the remaining twelve watersheds (Mission Creek, minor Naches River Tributaries, minor Columbia River Tributaries, Mad River, Swauk-Naneum, Wenas Creek, Lower Tieton, Little Naches, Entiat River, Wenatchee River, Taneum-Manastash, and Yakima River), all have at least one alternative that poses a high risk of cumula-

tive effects from management activities to soil and water resources (> 50% allocation to intensive timber management). It is important to understand, however, that individual subdrainages within these watersheds may have a different risk rating (high, medium, low) from the overall one shown for a given alternative. The amount and concentration of timber management activities within a given subdrainage will vary, requiring more site specific determinations to be made on a project basis. The watersheds are addressed individually in the following narrative.

MISSION CREEK - There are 40,959 acres in this watershed within the Forest protection zone boundary, which is nearly all of the watershed. Eight percent of it is composed of other ownerships. The City of Cashmere lies at the mouth of the watershed, where in the past there have been floods that have damaged homes along the channel and in the city. This watershed is characterized by steep and very steep slopes and very erodible soils that have formed in Chumstick sandstone residuum.

Alternatives B, D, and J all pose a high risk for cumulative effects to soil and water resources from management activities in this watershed (60% land allocation to intensive timber management; an additional 35% of the watershed subject to less intense harvest prescriptions).

Alternatives A/NFMA, C, H, and I all have a moderate risk for cumulative effects (between 35%-49% allocation to intensive timber management).

Alternatives E, F, and G all have a low risk for cumulative effects in this watershed, because only nine percent of the watershed is allocated to intensive timber harvest (National Forest plus other ownerships).

MINOR NACHES RIVER TRIBUTARIES - There are 54,485 acres in this watershed. As the name suggests, it is made up of several subdrainages that flow into the Naches River system. The watershed boundaries begin on the west near where the Bumping River enters the Naches River and extends downstream along the Naches

River to the Forest protection boundary, where the Naches River leaves the Forest.

Alternatives A/NFMA, B, D, C, H, I, and J all pose a high risk for cumulative effects from management activities on soil and water resources (between 59% and 81% allocation to intensive timber management activities; an additional 16% to 32% of the watershed subject to less intense harvest prescriptions).

Alternatives E, F, and G have a moderate risk for cumulative effects, because from forty-one to forty-nine percent of the land is allocated to intensive timber harvest.

There are no alternatives that pose a low risk for cumulative effects in this watershed.

MINOR COLUMBIA RIVER TRIBUTARIES - There are 44,245 acres in this watershed, stretching from the Kittitas County line to the Okanogan County line. It is made up of many separate subdrainages that flow directly into the Columbia River. In most cases, a large part of the acreage in these subdrainages lies outside of the National Forest protection boundary.

Alternatives A/NFMA and H both have a high risk for cumulative effects from management activities on soil and water resources (about 56% of the land allocated to intensive timber management; an additional 26% of the watershed subject to less intensive harvest prescriptions).

Alternatives D, C, I, and J all have a moderate risk for cumulative effects on the portion of these subdrainages that lie within the National Forest protection boundary. The percentages of land allocated to intensive timber management in these alternatives ranges from twenty-eight to thirty-six percent, with the total acres that could be affected by the addition of modified harvesting being about ninety-six percent of the available land base.

Alternatives E, F, and G pose a low risk of cumulative effects in this watershed (21% allocated to intensive timber management)

MAD RIVER - There are 61,035 acres in this watershed. The soil pattern in this watershed is complex, and soil types can change drastically within short distances. The soils in the northern part in the upper watershed position have developed in volcanic ash and pumice (mostly from Glacier Peak), and can be very erodible. In the Indian Creek, Tillicum Creek, and Kloochman Gulch parts of the watershed, there are some unstable soils that are subject to mass failures. These soils can produce large quantities of silt and clay when disturbed.

Alternatives A/NFMA, B, C, D, H, I, and J all have a high risk for cumulative effects from management activities on soil and water resources (between 48% to 77% of the land allocated to intensive timber management). When combined with less intensive timber management activities the range is from seventy-eight to eighty-eight percent of the total land available.

Alternatives F and G pose a moderate risk for cumulative effects within this watershed (36% and 29% of the watershed in intensive timber management, respectively, an additional 22% and 29% of the watershed subject to less intensive timber harvest prescriptions, respectively).

Alternative E poses a low risk of cumulative effects, because intensive timber harvest is allocated on only twenty-four percent of the watershed. This alternative also has another twenty percent of the land allocated to less intensive timber management activities; thus, the total amount of land available for some form of timber management activity is fifty-three percent of the watershed.

SWAUK-NANEUM - There are 81,748 acres in this watershed. As the name implies, it is composed of two separate and distinct drainage systems. The Swauk is the larger of the two, and lies west of Naneum Creek. Both drainages include some soil areas that are subject to mass failures, and both have some very erodible soils in them. The geology/soil patterns are complex and mixed, making it a difficult area to manage with regard to the protection of the soil and water resources.

Alternatives B and D both have a high risk for cumulative effects from management activities on soil and water resources (52% allocation to intensive timber management; an additional 34% of the watershed subject to less intensive harvest prescriptions).

Alternatives C, I, and J all have a moderate risk for cumulative effects because twenty-seven to forty-two percent of the land has been allocated for intensive timber management. The total amount of land affected by timber management activities, including the less intensive, ranges from seventy-seven to eighty-six percent of the entire watershed.

Alternatives A/NFMA, E, F, G, and H all have a low risk for cumulative effect because less than twenty-five percent of the land is allocated to intensive timber harvest. When other allocations that allow for less intensive timber management activities are included, the percentages range from sixty-seven to ninety-one percent of the watershed.

WENAS CREEK - The portion of this watershed that lies within the National Forest protection boundary is a relatively small area (11,109 acres). Furthermore, the area of concern lies high in the watershed, and is distributed across the upper part of many separate subdrainages.

All of the alternatives have more than fifty percent of the land allocated to intensive timber management. The percentages range from seventy-eight to ninety-two percent of the watershed for just the intensive timber management. When these percentages are added to other allocations that also allow less intensive timber management, the totals add up to between eighty-eight to one hundred percent of the watershed.

The soils in this watershed have developed mostly from basaltic materials, and although they are erodible, they tend to be stable. Also, since the area that is being considered lies mostly at the headwaters of several subdrainages, there is less risk of these systems creating a major watershed problem on Wenas Creek.

LOWER TIETON - There are 55,290 acres in this watershed. It is composed of many subdrainages that enter the Tieton River from both the north and south. This watershed starts just downstream from Rimrock Dam, near where the west side of the Soup Creek drainage meets the Tieton River, and extends downstream to the Forest boundary. There are some unstable soils on the south side of the river in the western part of this watershed; however, the remainder of the soils in this watershed are reasonably stable. The soils can be very erodible if left bare and unprotected, or if exposed to intensive storms.

Alternatives B, D, and J all have a high risk for cumulative effects from management activities on soil and water resources (between 54% to 65% of the watershed allocated to intensive timber management activities, an additional 31% of the watershed subject to less intense harvest prescriptions).

Alternatives A/NFMA, C, H, and I pose a moderate risk of cumulative effects, with between thirty-six and forty percent of the watershed allocated to intensive timber management activities. When these totals are added to the other allocations that allow less intensive timber harvest, timber management activities will occur on approximately eighty-five percent of the watershed.

Alternatives E, F, and G all have a low risk for cumulative effects (18%-19% allocation to intensive timber management). However, when this is added to the amount of other land that allows less intensive timber management activities, the total amount of land affected ranges from seventy-four to eighty-three percent.

LITTLE NACHES - The Little Naches is a large watershed, encompassing 94,023 acres. It lies entirely within the National Forest protection boundary, bounded on the west by the Cascade Mountains, on the south by the American River drainage, and on the north by the ridge that separates the Cle Elum and Naches Ranger Districts. The eastern boundary for this watershed is near the confluence of the American and the Little Naches Rivers. This watershed has some very unstable soil areas in it and areas that are highly erodible, particularly along the north side of the Little Naches River.

Alternatives B, D, and J pose a high risk for cumulative effects from management activities on soil and water resources (about 65% of the land allocated to intensive timber harvest, an additional 10% of the watershed subject to less intense harvest prescriptions).

Alternatives A/NFMA, C, F, G, H, and I all have between twenty-eight and fifty percent of the watershed allocated to intensive timber management activities. This added to the less intensive timber management activities that are allowed on other land allocations, adds up to between fifty-eight and seventy-five percent of the watershed.

Alternative E is the only alternative that poses a low risk of effects in this watershed (24% allocated to intensive timber management). Approximately 27% of this watershed will be subject to less intensive timber management activities.

ENTIAT RIVER - There are 174,202 acres in the Entiat watershed. Within the Forest protection boundary, there is not much land in other ownership. Most of these acres are in the eastern part of the watershed and along the bottomlands adjacent to the Entiat River. Most of the soils in this watershed have developed in volcanic ash and pumice. The soils are easily displaced and are subject to both wind and water erosion when the surface vegetation is removed, exposing the mineral soil.

Alternatives B and D both have a high risk for cumulative effects from management activities on soil and water resources in this watershed (50% of the land allocated to intensive timber management, an additional 10% of the watershed subject to less intense harvest prescriptions).

Alternatives A/NFMA, H, and J have a moderate risk for cumulative effects, because the land allocated to intensive timber management activities ranges from thirty-three to forty-five percent. When this is added to the less intensive timber management allocations, the combined totals range from sixty-one to sixty five percent.

Alternatives C, E, F, G, and I all have a low risk for cumulative effects, because all have twenty-five percent or less of the watershed allocated to intensive timber management activities. The

totals for all lands allocated for some type of timber management activity, both intensive and less intensive timber management, range from thirty-nine to fifty-seven percent of the watershed.

WENATCHEE RIVER - There are 160,676 acres in the Wenatchee River watershed. The Wenatchee River watershed starts roughly at the mouth of Lake Wenatchee (it also includes the waters draining into and out of Fish Lake), then extends towards the southeast to the Columbia River, covering all of the land within the National Forest protection boundary. Soils in this watershed are highly variable, having formed in a variety of parent materials. Some of these soils are very erodible and subject to mass failures if surface waters are allowed to concentrate as a result of management activity. Other soils in the watershed are excessively well drained and are very stable under most conditions.

Alternatives B and D both have a high risk for cumulative effects from management activities on soil and water resources (53% allocated to intensive timber management; an additional 20% of the watershed subject to less intense harvest prescriptions).

Alternatives A/NFMA, C, E, F, G, H, I, and J all have a moderate risk for cumulative effects from management activities on soil and water resources (between 30% to 49% allocated to intensive timber management). When the other allocations that allow less intensive timber management are added, the amount of land affected will range from seventy to seventy-three percent.

There are no alternatives that have a low risk for cumulative effects in this watershed.

TANEUM-MANASTASH - There are 54,485 acres in the Taneum-Manastash watershed. This watershed is made up of the Taneum Creek drainage and the Manastash drainage, from the headwaters to the National Forest boundary.

Alternatives B, D, and J all have a high risk for cumulative effects from management activities on soil and water resources. Alternatives B and D have seventy-two percent, and Alternative J has

seventy-eight percent of the watershed allocated to intensive timber harvest.

Alternatives A/NFMA, C, E, F, G, H, and I all have a moderate risk for cumulative effects. Alternatives A/NFMA, G, and H all have forty-two percent; Alternatives C and I have forty-four percent, and Alternatives E and F have thirty-five percent of the watershed allocated to intensive timber management. Timber harvesting is allowed on all lands in all allocations. However, lands other than those listed above are considered to be in less intensive timber management allocations where harvest activities may be carried out for the benefit of other resource values.

YAKIMA RIVER - There are 128,282 acres in the Yakima River watershed within the National Forest protection boundary. The watershed starts at the crest of the Cascade Mountains and extends east to the Forest boundary. The soils in this watershed are reasonably stable and are not noted for being high sediment producers. There have been rain-on-snow events in the past that have scoured some drainages (Cabin Creek and Log Creek), so severe erosion is possible, but is not probable under normal conditions.

Alternatives B, D, and J all have a high risk for cumulative effects from management activities on soil and water resources in this watershed (54% allocated to intensive timber management activities, an additional 23% of the watershed subject to less intense timber harvest prescriptions).

Alternatives A/NFMA, C, E, F, G, H, and I all have a moderate risk for cumulative effects, because between forty-three to forty-eight percent of the land is allocated to intensive timber management. The amount of land in other allocations that allow less intensive timber harvest is about seventy percent. Combining both adds up to seventy-five percent of all lands within this watershed that would be affected by some kind of timber management activity.

There are no alternatives that have a low risk for cumulative effects in this watershed.

c. Alternatives' Conflicts with Other Agency Plans and Policies

There are no known significant conflicts between the effects of the alternatives and the plans and policies of the State, other Federal agencies, the Yakima Indian Nation and local interest groups for the management of the soil and water resources on the Forest. There is considerable competition for the water produced on the Forest. The principal competitors include irrigation interests, small hydroelectric interests, and those interested in maintaining adequate fish habitat.

Soil erosion and transport of these materials off-Forest may be some cause of conflict. However, the anticipated amounts of delivered sediment should be minimal, if Forest and Regional Standards and Guidelines are met. In order to meet the Standards, the Forest will need to adhere closely to the Forest Service Nonpoint Source Management System.

d. Mitigation Measures for Soil and Water

The degree to which direct, indirect and cumulative effects are realized is a function of many variables, including the magnitude of proposed management activities and the level of success in project design and implementation. A critical step in the process is the identification and successful application of mitigation measures.

Mitigation measures for soil and water resources are designed to reduce the potential impacts of management activities on soil productivity and the beneficial uses of water. The public has expressed a high level of concern over the sufficiency and effectiveness of proposed mitigation measures on National Forest System lands.

Mitigation measures are developed through implementation of the Forest-wide Standards and Guidelines. Standards and Guidelines for all resource management activities provide general direction for analysis and design that requires more detailed follow-up in project level planning. The formulation of specific mitigation strategies to reduce resource risks will occur at the project level, where site conditions and required mitiga-

tion effectiveness can be better defined.

A wide range of mitigation measures are available for application at the project level. For example, mitigation measures to protect soil productivity might range from a decision to avoid building a road across unstable soils to selection of special site preparation techniques in a harvest unit. Mitigation measures linked directly to the protection of water quality might range from exclusion of a sensitive riparian zone from an activity area to the selection of special sanitary facilities at a developed campground.

The Forest-wide Standards and Guidelines for Soil and Water provide direction for meeting Forest Plan objectives for the management of soil productivity and water quality. For example, nonpoint source activities will be conducted using Best Management Practices (BMP's) and Forest Service Soil and Water Conservation Practices (SWCP's).

BMP's for water quality are implemented on National Forest System lands to comply with Washington State requirements for the protection of beneficial uses. SWCP's include specialized management practices, beyond those currently required by the State, to further insure protection of soil productivity and beneficial uses. Sullivan (et al., 1987) suggests that application of BMP's provides the needed basis for reducing effects of forest management activities. Application of these guidelines provides a basis for careful planning, proper design, and close scrutiny of Forest Service, contracted, and private sector activities and projects on National Forest lands.

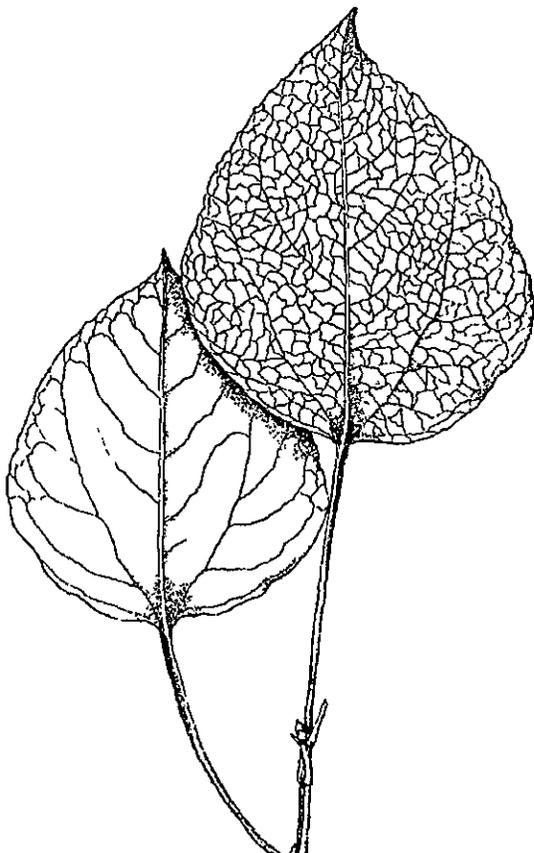

For private lands in watersheds with multiple ownerships, the BMP's for timber harvest and related activities are contained in the Washington Forest Practices Rules and Regulations. These are designed to protect water quality and beneficial uses following timber harvest on private lands.

Although most attention is focused on mitigation of impacts from timber harvest and related road work, the concepts outlined above are applicable to all other nonpoint source activities. For example, the General BMP's for water quality protection described in FEIS, Appendix J include practices for recreation, grazing and mining

activities as well as timber management and road systems. All activities scheduled under each alternative would adhere to these minimum legal requirements and would comply with all future refinements in Federal and State laws.

Refer to FEIS, Appendix J for additional details on BMP's for the protection of water quality. This appendix provides a description of the Forest Service process for the prevention and control of nonpoint sources and examples of the system. Refer to Forest Plan, Chapter V for a description of the monitoring strategy for the implementation and effectiveness of management practices.

Approaches to evaluating non-point source impacts on soil and water resources from timber harvest and related activities are discussed in the WRENS document (EPA, 1980). Other overviews of erosion, sedimentation, and water quality relationships are covered in Forestry and Water Quality (Brown, 1980), Forest and Water: Effects of Forest Management on Floods, Sedimentation, and Water Supply (H.W. Anderson, et al., 1976) and Logging Roads and Protection of Water Quality (EPA, 1975).

11. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON AIR

The management of Air as a resource for which the federal land manager is responsible was clearly stated in the Clean Air Act of 1970.

During the past eighteen years, the Wenatchee National Forest has been implementing a program which has complied with this direction. Rapid development of the program has occurred during the past five years and this trend towards more intensive air resource management is expected to continue as the implementation of this plan begins.

Forest management activities have effects of differing duration on this resource. Prescribed fire and wildfire are the largest contributors to the temporary degradation of air quality but the management of all vegetation is known to be important to the maintenance of the chemical components of the atmosphere. From this standpoint the management of all ecosystems in a "healthy and productive" state is crucial to our air resource management program.

a. Direct and Indirect Effects of Each Alternative on Air

Each alternative allocates portions of the Forest by priority of management activity. Within these alternative allocations there will be resource management activities which vary in intensity and extent. It is the variation in these specific activities which create impacts on our management of the Air resource.

The management of Air as a resource will not vary significantly between alternatives. There will be some short-term changes created by the implementation of resource management activities but all of these changes will be of limited duration and extent. Since the data concerning the impacts of various management activities on air quality is presently limited, the discussion of the effects of implementation of each of the alternatives will tend to be a subjective one.

1) Effects of Timber Management on Air Quality

The value of the many ecosystems within the boundaries of the Wenatchee National Forest in the maintenance of the chemical composition of our atmosphere is well recognized but remains unquantified. Maintaining all ecosystems in a thrifty condition is important to the management of our air resources. The need to improve the quality of the information available about this interaction has been documented and will be pursued during the implementation of this plan.

The activities involved in the harvesting of timber (road building, skidding, etc.) produce dust during the dry months of the year. The adverse impact of this dust on air quality is usually very short term in nature (hours to days) and very localized in extent. These effects are normally observed only during periods of active logging and log hauling.

Alternatives NC, B and J have the potential to impact air quality the most due to the higher volumes of timber harvested. Alternatives E, F and G have the lowest potential impact as they have the lowest harvest levels. Alternatives A/NFMA, C, D, H and I have mid-range harvest volumes and would have moderate potential for impact on the air resource,

2) Effects of Mineral Activity on Air Quality

The effects of mining on air quality cannot be described by alternative as they are dependent on each specific action undertaken and the management of the facilities developed. It is known that the development of large tailing piles, such as those located near Holden, Washington, can have significant, long term, localized effects on air quality if they are not stabilized in an appropriate manner.

3) Effects of Roads on Air Quality

The construction of roads during the dry periods encountered each year can have a temporary (hours to days) impact on air quality. These impacts are normally very transitory in nature and are the result of dust being created by heavy equipment or blasting. Occasionally, there are

effects of smoke from prescribed fire which is used to dispose of slash created during the right-of-way clearing.

Stabilization of new roads including cutbanks, fills, and the running surface, normally occurs within one of the initial disturbances. When roads are being heavily used, dust abatement techniques are often employed (watering and/or the application of road oil). The Forest does have areas where pumice soil types dominate the terrain. In these areas dust resulting from road construction and use will be more evident.

Due to variable soil conditions across the forest and the different running surfaces that would be used in each alternative, it is not possible to draw a direct correlation between the miles of road developed and the impact on the air resource.

4) Effects of Fire Management on Air Quality

The most noticeable impact on the quality of the Air on the Wenatchee National Forest is the smoke generated from either wildfire or prescribed fire. Both of these events generate quantities of smoke which adversely impacts the quality of the Air. The difference between these two types of activities is in the development of prescribed fire plans. The management of smoke is a key to the successful implementation of each plan. Environmental factors such as wind direction, atmospheric stability, and fuel moisture are critical environmental influences on smoke management. Additional parameters are considered to ensure optimum dispersion occurs.

This is in contrast to the situation encountered when wildfires occur, which is usually when the atmosphere is hot and stable. Under these conditions, dispersion of smoke is often minimal. During some of the more severe wildfire episodes experienced on the Wenatchee National Forest and in other areas of the Pacific Northwest, the air quality has been significantly impaired.

The management of wildfire remains constant through all alternatives but the number of acres treated for fuels management reasons varies by alternative. The acres expected to be treated are listed below. In interpreting the values listed in Table IV-20, it is appropriate to assume that the

more acres treated, the larger the impact on air quality. It is not possible to try to establish a direct correlation between these values and the quality of the air, however, as the type and season of treatment, which varies by alternative, will control the level of effect.

**TABLE IV-20
ACRES TREATED FOR FUEL MANAGEMENT**

Alternative	Acres treated per year
NC	7,000
A/NFMA	6,100
B	11,000
C	6,700
D	6,100
E	4,200
F	4,500
G	5,300
H	7,200
I	6,800
J	11,300

The treatment of additional acres should reduce the potential for large wildfires. It will increase the frequency of managed smoke emissions from the implementation of prescribed fire projects. The many variables involved in wildfire ignition preclude forecasting how much impact the prescribed fire program will have on wildfire ignitions. For this reason, the effects of fire management on air can only be related to the predicted fuels management program outlined above.

b. Cumulative Effects of Each Alternative

The management activities outlined in each alternative will not result in significantly different and lasting effects on the quality of the Air Resource. Short-term effects will differ in the amount of smoke emitted from the prescribed fire program. The number of acres of fuel treatment described under the vegetation management section will provide a general comparison of the acres of fuels treatment expected. A portion of these acres will be treated by prescribed fire.

Managing the Forest in a manner that promotes healthy ecosystems will help in maintaining the balance of atmospheric components. Some events and activities (wildfires, prescribed fires, timber harvest, and road building) will degrade the quality of the atmosphere for short periods of time in limited geographical locations.

Because of the transient nature of this resource the management of air is affected by the air management practices of the regulatory jurisdictions which surround the Forest. The Forest will maintain communication with these agencies and curtail activities which add additional pollutants when atmospheric conditions warrant. These episodes will be managed in compliance with all Federal, State, and local regulations.

c) Alternatives' Conflicts with Other Agency Plans and Programs

Air Resource Management activities will be approached in a cooperative spirit utilizing the best information from all Federal, State, and local agencies. All prescribed fire will be managed to comply with the State of Washington Smoke Management Plan, State of Washington Implementation Plan (SIP) and USDA Forest Service, R-6, Pacific Northwest Regional Guide. Conflicts with other agencies as a result of implementing this Plan should be minimal. Through the implementation of the Plan, the potential for future conflicts will be decreased.

d. Mitigation Measures for Air Quality

The role of Forest ecosystems in maintaining the chemical balance of the atmospheric components has been documented. The need to identify and quantify the contributions of the Wenatchee National Forest has been noted and will be developed during the life of this plan. The development of this data base will assist the managers of the Wenatchee National Forest in mitigating the effects of human activity on local air quality.

Mitigation measures which will be used for forest management activities can be divided into three primary categories. They are: dust control, smoke management, and chemical emissions. Outlined

below are the primary mitigation procedures which will be used as the implementation of this plan begins. Additional actions will be included as new technologies are developed.

1. DUST CONTROL

- a. Control season of activity.
- b. Apply dust abatement treatments.
- c. Design projects to minimize surface disturbance.

2. SMOKE MANAGEMENT

- a. Encourage more complete utilization of wood products in timber harvest activities to reduce the need for applying prescribed fire.
- b. Encourage the gathering of firewood by the public. Emphasize the value of dry wood to clean combustion. Utilize commercial firewood sales to help reduce the amount of residue in need of disposal.
- c. Support research which will help in reducing smoke emissions and develop technologies which will replace burning.
- d. Apply state of the art methodology to all prescribed burning projects including the modeling of atmospheric conditions to evaluate dispersion. Utilize consumption models to predict the components and amount of smoke to be produced by each prescribed fire.

3. CHEMICAL EMISSIONS

- a. Continue to work with all agencies to review Point Source Development permit applications for those projects which have the potential to impact the Wenatchee National Forest.

12. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON MINERALS

The Forest's policy is to encourage and facilitate mineral exploration and development on all lands not withdrawn from mineral entry. That policy will not change as a result of implementing any one of the alternatives. Considering the limited number of additional withdrawals recommended in the alternatives, it also appears that present management of mineral-related activities would not change significantly as a result of implementing any one of the alternatives.

Demand for access to National Forest lands for the purpose of mineral exploration and development is expected to increase over the long term. This will not change as a result of implementing any of the alternatives. Operating plans will continue to be submitted for approval in a timely manner. The regulations under which those operating plans are processed also will not change as a result of implementing any of the alternatives. Mineral commodities, deposit locations, and deposit characteristics will not vary by alternative, and the demand for mineral commodities is expected to increase regardless of the alternative selected. As described in Chapter III, minerals are classified as being locatable, leasable, or salable, and the laws by which each type is disposed of and managed will not change by alternative. Those lands that are not withdrawn from mineral entry will remain subject to exploration and development under the mining and mineral leasing laws.

Under the various alternatives, certain lands are recommended for withdrawal from mining activity while other lands are recommended for management by various prescriptions. The manner in which the lands are to be managed under each alternative will have an effect on the availability of those lands for mineral entry. It will also have an indirect effect on the cost of conducting exploration, development, and reclamation activities. Not only may implementation of the plan preclude future exploration and development in areas recommended for withdrawal, but since management prescriptions and the management of other resources may affect the actual cost

of operating, the management approach may also influence interest in exploring some areas for their mineral resources.

For the most part, the value of mineral resources is not well quantified. Therefore, it is difficult to quantify the effects on minerals that each alternative would have in terms of dollars, tons at a certain grade or billions of BTU's. Likewise, since specific activities have not been proposed, the indirect effects of protecting other resources from mining impacts cannot be specifically quantified in terms of delays, cost of operating, cost of reclaiming or in terms of production. These impacts will be analyzed and quantified when specific activities have been proposed, and the location, scope and timing of an operation is known. As a consequence, the effects are best shown by analyzing the relative degree to which management prescriptions may increase the cost of operating, limit the availability of lands for mineral exploration and development, or constrain proposed mineral activities.

For this analysis, management prescriptions have been grouped by their relative sensitivity or restrictive nature. These groups are shown on Tables IV-21 through IV-25. For example the prescriptions requiring complete withdrawal of lands from mineral entry (management prescriptions WI-1, RN-1, and WS-3) are most restrictive because the withdrawals will usually preclude mineral entry. Other than possible use for panning, sluicing and mineral collecting, the only mineral activities allowed in the area will be those conducted on mining claims, leases, or permits having valid existing rights established prior to the date of withdrawal. Prospecting permits, leases, and mineral permits may be allowed in some circumstances. However, since wilderness does not vary between alternative and proposed withdrawals do not vary much between alternatives, the effects that these prescriptions would have do not vary significantly between alternative.

The second group of prescriptions, which are considered to be "highly" sensitive toward mineral-related activities (see Table IV-21 through Table IV-25), includes those lands managed as "Scenic" or "Recreational" Rivers, as "Dispersed Recreation Unroaded-Nonmotorized" areas, as "Developed Recreation Sites", as "Experimental

Forests", as "Old Growth" or as "Special Interest" areas. The least sensitive management areas are those lands allocated to "General Forest" or "Range Management" strategies. In all except the first group, mineral activity is not restricted beyond reasonable precautions for environmental protection and to insure management objectives for the affected land are met, if at all possible. However, the RE-1, SI-2, ST-1, and ST-2 prescriptions could result in the withdrawal of localized areas where resources are especially sensitive and cannot be protected by measures other than withdrawal. The use of these prescriptions does vary between alternative, and, therefore, both the direct and indirect effects on minerals does vary somewhat between alternatives. The effects are summarized as follows.

a. Direct and Indirect Effects of Each Alternative on Mineral Resources

1) Effects of Recreation (Developed, Dispersed and Unroaded) on Mineral Resources

The effect that the recreational setting has on mineral resources comes in the form of withdrawals (when needed for developed recreation sites, special interest areas, etc), delays, increased costs associated with protecting the recreational resource from the impacts caused by mineral activities, and the negative influence that managing areas as roadless areas might have on interest in conducting mineral activities. As with the other resources, this effect cannot be quantified any more than is shown below. However, it is assumed that those alternatives which provide for less emphasis on roadless and non-motorized recreational resource management would have fewer impacts on mineral resource availability than those alternatives with more roadless or non-motorized emphasis. The amount of area managed as roadless or non-motorized does vary some between alternatives, and that amount varies from a minimum to a maximum in the following order. Alternatives J, B, D, NC, A/NFMA, H, C, I, G, F, E.

The dispersed recreation activities will have little effect on mineral resource availability, but the developed recreation activities may require a withdrawal from mineral entry to ensure appro-

ropriate protection. As a consequence, the developed recreation activities can have adverse impacts on the availability of mineral resources. In general terms, the area eventually withdrawn for developed recreation sites may vary from a greater to a lesser amount in the following order: J, B, D, NC, A/NFMA, G, H, C, I, E and F. The specific effects that any such development and associated withdrawal would have, however, will be assessed when a recreation development is proposed.

2) Effects of Wild and Scenic Rivers on Mineral Resources

Designation of Wild and Scenic Rivers can affect the availability of mineral resources. River segments classified as "Wild" are withdrawn from mineral entry. Except for possible panning, sluicing and mineral collecting, only mining activities with valid existing rights established prior to the date the river was designated as a Wild River, can occur within segments. However, since all but two of the recommended Wild segments lie within already existing wilderness areas which are also withdrawn from mineral entry, the effect of having the rivers designated as Wild Rivers would have little new effect on mineral resources.

Only under Alternatives E and F would both river segments (the Entiat River between Cottonwood Campground and the wilderness boundary, and the lower mile of the Waptus River) lying outside wilderness be recommended for "wild" designation. As a consequence, the effect that Wild and Scenic designations would have on the availability of mineral resources would be greatest under Alternatives E and F.

Scenic and Recreational River segments are not withdrawn from mineral entry, and therefore they remain available for claim staking, mineral leasing and the issuance of mineral permits. Even though they are not withdrawn, however, if they become part of the Wild and Scenic River System, mining activities will have to be conducted in keeping with a management plan established for the river. It is assumed that the management plan could cause some delays and could cause the cost of operating to increase. As a consequence, those alternatives which call for more Scenic and Rec-

reational designations may have a greater impact on mineral resource availability. Conversely, alternatives that would designate fewer rivers as part of the System would have a relatively smaller effect. Those effects range from smaller to larger in the following order: Alternatives NC, J, B, D, A/NFMA, G, H, C, I, F and E.

3) Effects of Cultural Resources on Mineral Resources

All persons, whether prospecting, locating or developing the mineral resources must comply with the cultural resource rules and regulations of the Forest Service. The Forest Service is responsible for obtaining adequate cultural resource inventory data and is responsible for ensuring the adverse impacts on cultural resources are mitigated, but the cost of mitigating those impacts are the responsibility of the operator. Complying with the requirements for inventories and mitigation could result in delays and increased costs. However, since the cultural resource rules and regulations are the same in all alternatives, the effect that such management would have would not vary by alternative.

4) Effects of Scenery on Mineral Resources

As with many of the other surface resources, the effects that scenery resources will have on mineral resources are in the form of increased operating and reclamation costs. These costs cannot be quantified until mining activities are proposed. Since visually sensitive areas vary little by alternative, it could be assumed that the effects would vary little by alternative. However, some of the alternatives do emphasize retention and/or preservation visual quality objectives, and those alternatives would tend to increase the costs of operating and reclamation. Those alternatives that do not emphasize visual resource protection would tend to decrease the relative cost of operating. Therefore, the relative effect that visual resources might have would range by alternative from less restrictive to more restrictive objectives in the following manner: Alternatives J, B, D, A/NFMA, NC, H, C, I, G, F and E.

5) Effects of Wilderness on Mineral Resources

Since wilderness is withdrawn from mineral entry, the impact that wilderness has on the availability of mineral resources is significant. The only mining-related activities that can be conducted in wilderness areas are prospecting, and exploration or mining activities conducted under valid existing rights established prior to the date the area was withdrawn as wilderness. However, wilderness does not vary by alternative, and therefore the effects that wilderness has on mineral resources do not vary by alternative.

6) Effects of Wildlife on Mineral Resources

The effect that wildlife resources will have on mineral resources comes in the form of increased or decreased operating and reclamation costs, and in the form of delays to accommodate seasonal restrictions for wintering habitats, for fawning and calving grounds, and for nesting, breeding, and fledgling periods for deer, elk, mountain goat, sheep and various threatened, endangered or sensitive species of wildlife. Since threatened and endangered species and their associated habitat does not vary by alternative and they are protected by the Threatened and Endangered Species Act in all alternatives, the effect that those species will have on mineral resources would not vary by alternative. Likewise, the location of fawning, calving, lambing and kidding grounds generally does not vary by alternative, and therefore the effects that those areas would have does not vary by alternative. However, the effect of managing for the deer, elk, mountain goat and sheep habitat, does vary somewhat between alternatives, and those effects on mineral resource availability vary relatively from less restrictive to more restrictive objectives in the following order: Alternatives J, B, D, A/NFMA, NC, H, C, I, G, F and E. The actual effect that wildlife habitat will have on mining activities in the form of delays or cost will be assessed and quantified when activities are proposed.

7) Effects of Timber Management and Roads on Mineral Resources

The effect that increased roading and utilization of the timber resources would have on mineral resources is generally considered to be beneficial. As new roads are built and timber is harvested,

access to unexplored areas is improved and mineral exploration and development opportunities are enhanced. Closure of roads would not preclude access reasonably needed for mineral-related activities but may tend to discourage such activity. It may also limit some rockhounding activities or at least make conducting such activities more difficult. Therefore, in general terms the indirect effect that roads and timber harvesting activities may have on minerals varies by alternative in the following order (eg., maximum to minimum road construction and timber harvesting activity): Alternatives J, B, D, H, A/NFMA, NC, C, I, G, F and E. The actual effect cannot be quantified more than what is shown as direct effects on mineral resources.

8) Effects of Range Management on Mineral Resources

The effect that range management will have on mineral resources comes in the form of increased or decreased operating and reclamation costs. However, as with the soil resources, the forage resources do not vary significantly by alternative. As a result, the impact that this activity would have on mineral resource availability would not vary much by alternative.

9) Effects of Old Growth and Threatened and Endangered Species on Mineral Resources

Section 7 of the Endangered Species Act of 1973 requires the Forest Service to ensure that an action is not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of any such species' critical habitat, unless that agency has been granted an exemption for such action. Based upon 45 F.R. 78905, November 26, 1980, an operating plan could be rejected based on Section 7 if there is an unavoidable conflict with an endangered species habitat. As a consequence, the effect of these resources can be the same as any withdrawal. On the other hand, even though an operator can be required to include protective measures for sensitive species, it is less likely a plan could be disapproved based upon impacts to a sensitive species or it's habitat. In any case, the requirements of the Endangered Species Act and the manner in which we manage for such resources is the same in all alternatives.

10) Effects of Unique Ecosystems and RNA's on Mineral Resources

As with many of the other resources, the effect of managing for unique ecosystems and Research Natural Areas can either be restrictive in nature by limiting the scope and location of activity, or preclude such activity if an area is withdrawn from mineral entry. If withdrawn the effects would be the same as discussed under wilderness above. As indicated under the Unique Ecosystem section of this chapter, protection of these areas would range from minimal to maximum in the following order: Alternatives NC, J, A/NFMA, H, C, I, G, E, B, D and F. However, the protection of Research Natural Areas would vary only slightly by alternative since all but one RNA is either formally proposed as a Research Natural Area or is located within wilderness in every alternative.

11) Effects of Water, Air and Fisheries on Mineral Resources

Protecting air quality, water quality and fish habitat from the impacts of mining related activities may cause delays and increase the cost of conducting those activities. However, since mining operators are required to meet all Federal and State water and air quality requirements no matter which alternative is implemented, the effects of managing for those resources will actually vary little between alternatives. The actual effect in terms of increased cost of operation or delays is assessed when activities are proposed.

12) Effects of Soil on Mineral Resources

The effect that soil has on mineral resources generally comes in the form of delays and increased operating costs which are involved with ensuring minimal erosion and appropriate reclamation. However, since soil erosion characteristics do not vary by alternative, the effect that soil will have on mineral resource activities does not vary much by alternative.

TABLE IV-21
EFFECTS OF THE ALTERNATIVES ON A FOREST-WIDE BASIS
(ACRES AND PERCENTAGES OF FOREST WITHDRAWN OR MANAGED AS HIGHLY
SENSITIVE AREAS) ^{1/}

Alternative ^{3/}	Area Other Than ^{2/} Wilderness Where Management Prescrip- tions Call Specific- ally for Withdrawal Acres/ % of Forest	Highly Sensitive Management Area (Generally open to mineral entry, but highly restrictive protective mea- sures may apply). Acres/ % of Forest
A/NFMA	1,717 acres (0.08%)	411,199 Acres (18.9%)
B	2,247 Acres (0.1%)	384,868 Acres (17.8%)
C	2,247 Acres (0.1%)	482,876 Acres (22%)
D	2,247 Acres (0.1%)	384,868 Acres (17.8%)
E	3,837 Acres (0.2%)	654,598 Acres (30%)
F	3,689 Acres (0.2%)	606,495 Acres (28%)
G	2,247 Acres (0.1%)	536,513 Acres (24.8%)
H	1,717 Acres (0.08%)	417,325 Acres (19%)
I	2,247 Acres (0.1%)	482,876 Acres (22%)
J	2,247 Acres (0.1%)	365,046 Acres (16.9%)

^{1/} Highly sensitive areas are generally open to mineral entry, however, "seasonal restrictions," "no surface occupancy stipulations" or other highly protective measures may be required for approved mineral-related activities.

^{2/} Wilderness includes 841,034 acres which is 38.9% of the Forest. This does not change by alternative. Current administrative withdrawals include approximately 7,627 acres, which is 0.35% of the Forest. These may or may not be continued depending upon the results of the withdrawal review process.

^{3/} Figures for Alternative NC are not available

J	193,559	14%	1,399	0.1%

1/ The amount of area identified may include duplicated acreages when an area is classified prospectively valuable for more than one energy mineral resource

2/ Highly sensitive areas are generally open to mineral entry, however, "seasonal restrictions," "no surface occupancy" stipulations, or other protective measures including some withdrawals may be required

3/ This does not include wilderness which is 531,086 acres or 40% of the total area identified as being prospectively valuable for energy mineral resources. None of the alternatives would change the location of wilderness

4/ No acreage figures are available for the NC alternative

13) Effects of Alternatives in general on mineral resources

As with the effects that the other resources have on mineral resources which are addressed above, the effects that each alternative in general would have cannot be quantified in terms of dollars or tons at a certain grade, but they can be shown in relative terms. Except in those areas that are withdrawn from mineral entry, the public has a statutory, non-discretionary right to explore the public lands for locatable minerals. Upon confirmation that a discovery of a valuable mineral deposit has been made, they have the right to mine. The Forest Service does not have authority to deny an operating plan filed to conduct mineral activities on public lands, but they do have the authority to approve only those activities that are reasonably necessary for mining purposes. The authority also exists to restrict those activities to a degree that insures no undue degradation of the environment occurs.

The public also has an exclusive right to explore for leasable minerals and to produce both leasable and salable minerals from public lands if they hold a valid lease or permit. Whether leases or permits will be issued, and the environmental constraints which are attached, depends on whether the associated mineral activities meet the management strategies for the land.

Specific leasing decisions will be made when applications to lease are received, or the Forest Service initiates oil and gas leasing activity in keeping with the Oil and Gas Leasing Reform Act of 1987. When claimants have a right to mine or produce minerals, they are also guaranteed reasonable access for mining purposes. The same rights apply to withdrawn areas if valid rights perfected prior to the withdrawal exist. Operators will, however, be expected to reasonably protect the sensitive resources for which any area is being managed. This is especially important within the environmentally sensitive areas or roadless areas where "highly" sensitive management prescriptions have been adopted. In those areas where environmental protection measures are required in approved operating plans, leases and permits will be more stringent. Reclamation objectives and mitigation measures may also be more difficult to satisfy. As a consequence,

operating costs will be higher than they are in areas managed under less sensitive resource objectives. This may influence interest in exploring these areas for their mineral resources, but it would not preclude exploration or development should demand justify the higher cost of operating in these areas.

The effect that the management prescriptions used for "highly" sensitive management areas will have on mineral resources, again, cannot be accurately quantified in terms of tons at a certain grade or in dollars. However, Figures IV-9 through IV-11 visually depict the different restrictive effects that implementing the various alternatives would have. As these three figures and Tables IV-21 through IV-23 show, 841,034 acres (39 percent of the total Forest acres) have already been withdrawn as wilderness. The only mineral activities allowed within these areas will be those authorized by valid existing rights perfected prior to the area's withdrawal as wilderness. As a consequence, the area is no longer available for exploration and development under the mining and mineral leasing laws. The quantified effect of these withdrawals has not been determined, but since this impact does not vary by alternative, it will not be discussed further in this part of the analysis.

In general terms, if withdrawing lands, restricting use of and access by motorized equipment, limiting road construction activities, limiting mining-related surface disturbing activities or increasing reclamation and environmental protection requirements for recreation, scenic, wildlife and other purposes are considered to cause more negative impacts on mineral resource availability than an opposite or less restrictive approach to management would, then the effect that the alternatives have on mineral resource availability varies relatively from smaller to greater in the following manner:

Forest-wide (no consideration for mineral resource potential)
Alternatives J, B, D, A/NFMA, NC, H, C, I, G, F and E (see Table IV-21 and Figure IV-9).

Locatable mineral resources (High to moderate potential)
Alternatives A/NFMA, NC, B, D, J, H, G, C, I, F and E (see Tables IV-22 and 23, and Figure IV-10).

Energy mineral resources (oil and gas, coal and/or geothermal)
Alternatives J, B, D, A/NFMA, NC, H, C, I, G, F, E (see Tables IV-24 and 25, and Figures IV-11).

As an example, Table IV-21 indicates how much of the Forest would be proposed for additional withdrawals and what portion of the Forest would be managed as highly sensitive areas. Tables IV-22 and IV-23, on the other hand indicate how the withdrawal or highly sensitive management approach would affect areas having potential for the occurrence of locatable mineral resources and/or leasable mineral resources.

As the figures and tables show, Alternative A/NFMA would result in the withdrawal of an additional 1,717 acres, with 309,332 acres managed under "highly" sensitive management prescriptions (14 percent of the total Forest acres). This would have the effect of limiting, "highly" constraining or increasing the cost of conducting mineral-related activities on: (1) 20,458 acres (18 percent) of the area identified as having a "high" and "moderate" potential for the occurrence of locatable minerals; (2) 12,911 acres (17 percent) of the area classified "prospectively valuable" for oil and gas; (3) 42,103 acres (9 percent) of the area classified "prospectively valuable" for geothermal resources, and (4) 98,603 (18 percent) of the acres classified "prospectively valuable" for coal resources. The withdrawal areas would not affect any "high" potential locatable mineral areas, but would affect 869 acres classified "valuable" for coal.

Alternative C would result in the withdrawal of an additional 2,247 acres with 436,915 acres managed under "highly" sensitive management prescriptions (20 percent of the total Forest acres). This would have the effect of limiting, "highly" constraining or increasing the cost of conducting mineral-related activities on: (1) 25,652 (23 percent) of the area identified as having a "high" and "moderate" potential for the occurrence of locatable minerals; (2) 35,192 acres (17 percent) of the area classified "prospectively valuable" for oil and gas; (3) 48,209 acres (8 percent) of the area classified "prospectively valuable" for geothermal resources; and (4) 140,896 acres (26 percent) of the area classified "prospectively valuable" for coal resources. The withdrawal

areas would not affect any "high" potential locatable mineral areas, but would affect 869 acres classified "valuable" for coal. It also would affect 530 acres classified "prospectively valuable" for oil and gas resources, which is also identified as an "area of critical mineral potential."

Using the referenced Figures and Tables, effects of a similar nature caused by Alternatives NC, B, D, E, F, G, H, I and J can be identified and compared.

The effects that the alternatives have on "areas of critical mineral potential" (ACMP) are essentially covered by the above discussion. However, for the benefit of the reader a little more detail is being provided. The Forest has four "areas of critical mineral potential". One lying in Townships 20 and 21 N., Ranges 17,18, 19 and 20 E., appears to have been nominated primarily for its oil and gas resource potential. That ACMP area is included with the oil and gas discussion above, and is addressed in the Tables and Figures.

The other three ACMP areas lie on the Naches Ranger District. One of those areas lies wholly within a designated wilderness and the other two lie partially within wilderness. Since wilderness does not change by alternative, the effects that the alternatives would have on that portion of the ACMP's lying within wilderness areas does not change by alternative.

The two areas which have portions lying outside wilderness would be managed differently under the various alternatives (Area #1 in T.17N.,R.13E. and Area #2 in T.17N., R.11E.). The amount of Area #1 managed as General Forest, Scenic Travel Routes, Developed and Dispersed Recreation, Old Growth Habitat and as a Scenic River changes by alternative. As a consequence, Alternatives A/NFMA, B, D, C, H, I and J would have less effect on minerals than would Alternatives E, F and G. Conversely, Area #2 would be managed for Scenic Travel, and Dispersed and Developed Recreation under all the alternatives. Since all of these prescriptions are considered to be highly sensitive to land-disturbing activities, it appears that the effects would not vary significantly by alternative.

As far as recreational panning, sluicing, dredging and collecting is concerned, none of the alternatives specifically preclude such activities nor do they withdraw areas specifically for that purpose. If such activities can be conducted in a manner that is compatible with management objectives for the area, the standards and guidelines provide for the approval of such activities. As a consequence, it does not appear that the effects would vary much by alternative. If anything, they would vary in the same relative manner as is shown for locatable minerals above.

Common variety minerals, on the other hand, occur throughout the Forest and it appears that none of the alternatives will significantly affect the availability of that resource.

b. Cumulative Effects of Each Alternative on Minerals

Since we do not know where, what type, or when mineral activities will be conducted, the cumulative effects that mineral-related activities may have on other resources must be addressed when activities are actually proposed. As a consequence, the cumulative effects that mineral-related activities may have on other resources have not been addressed in any detail. On the other hand, the cumulative effects that the alternatives have on mineral resource availability have been addressed in some detail.

Even though an area has a "high" or "moderate" potential for the occurrence of mineral resources, it is of little value if the area is off limits to mineral exploration and development, or constrained by protective management prescriptions. Formal withdrawals have the effect of placing lands off limits unless prior existing rights are involved. Management prescriptions, on the other hand, can take the form of a "de facto" withdrawal when discretionary actions such as the leasing and selling of minerals is involved. Managers may choose not to issue a lease or a permit if the related activities would be incompatible with the management objectives for the land, or may strongly constrain mineral activities to meet the management objectives for the land. Since mineral deposits are not distributed randomly, but are associated with unique geologic conditions, a few

withdrawals accompanied by highly restrictive stipulations attached to leases or permits could effectively eliminate production of certain mineral commodities from the forest lands.

In addition to the wilderness, there are approximately 7,627 acres of Forest Service administrative withdrawals and 67,651 acres of powersite and reclamation withdrawals which are currently being reviewed as required by Federal Lands Policy Management Act. As they are reviewed, a decision will be made as to whether they should be retained, modified or terminated. That decision has not been addressed in any one of the alternatives. Therefore, other than the fact that they presently exist and contribute to the cumulative impact of mineral withdrawals, that effect cannot be quantified except by indicating which acreage is currently withdrawn. The effect of that does not vary by alternative.

By implementing the various alternatives, an additional 18 to 35 percent of the "high" and "moderate" potential locatable mineral resource areas, 15 to 32 percent of the potential oil and gas areas, 24 to 38 percent of the potential coal resource areas, and 8 to 18 percent of the potential geothermal resource areas would be affected by highly sensitive management strategies. Cumulatively, the consequences appear to be most severe on geothermal resources where 70 percent of the area classified "prospectively valuable" for geothermal resources is already withdrawn as wilderness, and an additional 8 percent to 16 percent would be withdrawn or "highly" restricted as a result of implementing the various alternatives.

To add to the cumulative effects of the existing withdrawals, and any new withdrawals initiated as a result of implementing the Forest Plan, are those withdrawals made effective when a new application for a power project is received. Not only is the site automatically withdrawn from mineral entry when the application is received, but it remains withdrawn and there is presently no mechanism for revocation. Since we do not know where, when, or what type of hydroelectric project will be applied for, there is no way to quantify the anticipated impact that future proposals of this nature will have on minerals availability.

c. Alternatives' Conflicts with Other Agency Plans and Policies

The mineral management objectives and policy of the Forest Service are quite similar to and compatible with the objectives and policy of other Federal, State, and local agencies. Considering the regulatory control and mineral management policy of the Forest Service, it appears that there are no significant conflicts between the effects of the alternatives and the objectives of the other agencies.

d. Mitigation Measures for Mineral Resources

The impacts that each alternative would have on mineral resources has been measured in terms of land availability for mineral exploration and development activities and in terms of regulatory constraints. As a mitigating measure for these impacts and to insure lands remain available for mineral exploration and development if at all possible, existing withdrawals will be reviewed for need, and new withdrawals will be periodically reviewed as well. If they are not necessary for adequate protection of sensitive resources or substantial investments, then the withdrawals will be revoked and the land reopened to mineral entry. Stipulations attached to leases, permits, and approved operating plans as a result of management prescriptions will also be reviewed for reasonableness and effectiveness, as well as their influence on mineral activity. When warranted, stipulations will be modified.

The mitigating measures used to protect or minimize the impacts caused by mining related activities are discussed under the other resource narratives in this chapter.

13. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON ROADS

a. Direct and Indirect Effects of Each Alternative on Roads

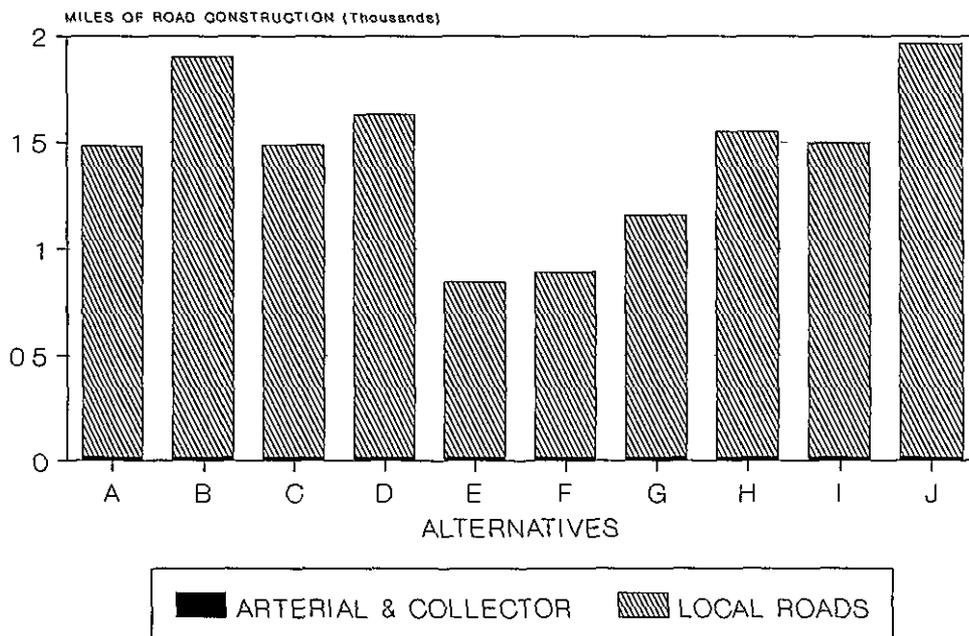

It is the effects of roads on the environment that is of concern to both the public and the managers of the Wenatchee, and these have been addressed under the individual environmental components throughout Chapter IV. However, there are also direct effects on the road system created by the implementation of a land use alternative, as described below. The information presented here may be useful in comparing the direct and indirect effects of the road system on soil, water, wildlife, scenery, recreation, cultural and other environmental components found elsewhere in this chapter.

(1) **Arterial and Collector Roads**

The proposed construction and reconstruction of the arterial and collector system for the various alternatives is shown on Table IV-26. As the table shows, these roads are not as sensitive to the alternative development process as the local roads are. These roads are the primary and secondary travel routes, the people movers. They access large and popular land areas. A typical arterial road on the Wenatchee National Forest begins as a double lane, asphalt-surfaced road that takes off from a State highway or is an extension of a County road. Typically these roads are located in valley bottoms adjacent to major rivers. They provide access to several developed sites, numerous trailheads, lakes, timber sales, and usually end at a wilderness trailhead. These roads collect timber traffic and disperse recreation traffic.

It is the type and amount of traffic generated by this mix of resource activities that determines the location, standard, and management of these facilities. As these roads proceed up the valleys, the amount of traffic decreases as people "get off" the system at the various recreation sites and the size of the tributary area and the amount of timber traffic becomes less and less. As the traffic decreases, so does the road standard and the level of service that the road provides. Ultimately, as the roads approach the wilderness, they become single-lane dirt roads. These more primitive roads provide a more appropriate setting for those individuals about to enter the wilderness and serve to discourage the less determined users.

X = Applies to this alternative

NA = Not applicable to this alternative

SL = Service Level See Chapter III for a description

^{1/} Data is not available for the NC alternative

Forest Service collector roads access the smaller drainages. Occasionally they cross over ridges to connect with the arterial roads in the major drainages. Collector roads have less traffic and provide lower levels of service.

The recreation use patterns within these road corridors is well established and is not expected to change significantly between alternatives. The construction and reconstruction is assumed to occur in the next 10 years.

Alternatives E and F will require a reduced level of development. There are a few primitive single-lane collector roads that are currently operating at or near their safe and efficient capacity and these roads are sensitive to the allocation of the land within their tributary area. Because of the reduced harvest level in Alternatives E and F, it may not be necessary to reconstruct roads like the Upper Chiwawa or Mission Creek.

The allocation of forest land to roadless management prescriptions will have an effect upon the share cost roads systems in "checkerboard" ownership areas. Because the allocations do not change between alternatives within the Alpine Lakes Management Unit, there will be no change from the existing situation in the share cost program within that area. There will also be no significant changes in the Oak Creek and Entiat Summit areas between alternatives. These areas are essentially developed. It is the allocation of the National Forest land to roadless prescriptions in the Cle Elum Ridge, Manastash and Taneum areas that varies between alternatives. There will be minor changes in the share cost systems in Alternatives B, J and D, a moderate impact in Alternatives A/NFMA, C, H, and I, a greater impact in Alternative G, and a significant impact in Alternatives E and F. Regardless of the alternative selected, the owner of the intermingled land in this area can be expected to access and manage the private lands, and has a right to reasonable access across National Forest land. When the surrounding land is allocated to roadless prescriptions, the Forest Service will not share in the construction of roads.

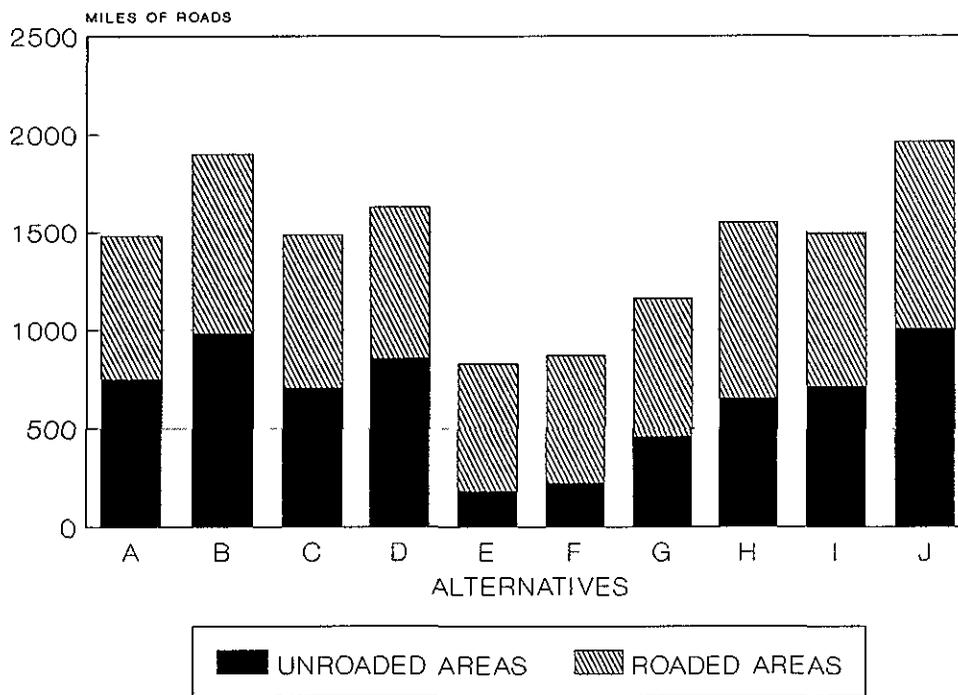

(2) Local Roads

In contrast to the arterial and collector roads, local roads are sensitive to the alternative development process. As shown in Table II-3a, the miles of timber purchaser roads vary with the amount and rate of timber harvest. These are the log movers. Although these roads are built by the purchasers of National Forest timber, they do provide opportunities for dispersed recreation in a roaded natural or roaded modified setting.

An analysis of the road systems required for the first entry into unroaded areas on the Wenatchee National Forest over the past 10 years has shown that there are an average of 5.5 acres accessed for each acre that is harvested during the initial entry. The reasons for this include timber size, age, visual quality objectives, wildlife concerns, and legal and policy requirements for clearcut size, leave strips, etc. These issues, concerns, and opportunities are identified during project planning and design and result in an increase in the number of acres accessed, relative to the number of acres actually managed. Because of these assumptions, and the concern over the rate of development in unroaded areas, this is an item that will be included in the monitoring plan. The reviewers of this document should be aware that development sales in unroaded areas will change the recreation setting on more acres than are actually harvested during the initial entry.

All alternatives will require new road construction. Figure IV-13 shows the long-term total miles of new road construction that are projected for each alternative.

FIGURE IV-13
TOTAL MILES OF NEW ROAD TO BE CONSTRUCTED

b. Cumulative Effects of Each Alternative

It may be more correct to identify the cumulative effects that roads have on other environmental components; however, the implementation of the various alternatives will have a cumulative impact on the Forest road system and the users of that system. The incremental effect, measured in the amount and type of traffic generated, determines the selection of road standards and their levels of service. This is particularly true of the arterial and collector road systems. The standards and service levels for the different alternatives are found in Table IV-26. The number or miles of road suitable for public use by passenger cars and high clearance vehicles, found in Table II-3a, could also be viewed as a cumulative impact on the accessibility of the Forest to road users. The variation in miles is a product of direction for road construction or operation found in the prescriptions applied in that alternative.

c. Alternatives' Conflicts with Other Agency Plans and Policies

Because of their capacity, the traffic impacts on the State highways are not expected to vary significantly between alternatives and will fall within the ranges identified in Chapter III.

The traffic impacts on Yakima County and Kittitas County roads are not expected to vary significantly between alternatives, also because of their capacity.

Because of the many primitive County roads, there will be a need for close coordination with Chelan County Public Works Department regardless of the alternative selected.

d. Mitigation Measures for Roads

It is generally accepted that roads generate most of the effects on water, soil, fish, wildlife, and scenery. In addition to changing the recreation setting, they also have potential to change recreation use patterns in adjacent roadless areas and wilderness areas. The surest method of mitigating those impacts is to avoid building roads. If it is not possible or practical to do this, the minimum amount of road of the lowest standard can do much to reduce those probable adverse environmental impacts that cannot be avoided. In addition to the Standards and Guidelines included in this plan, the Forest Service Manuals and Handbooks contain the direction necessary to mitigate the effects of roads with proper location, design, and management. Much of the recent research conducted by the Forest Service and others in the Blue Mountains, the Idaho Batholith, the Experimental Forests, and elsewhere is incorporated into the directives system. No road is constructed without appropriate environmental analysis; nevertheless, the potential risk to the environment is proportional to the amount of roading.

Road management, and in particular, road closures can mitigate the impacts caused by roads. The miles of road expected to be closed for the various alternatives is found in Table II-3a in Chapter II.

14. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON FIRE MANAGEMENT

For the purpose of this plan, wildfire and prescribed fire will be addressed together since the relationship between the two are inseparably intertwined. In this planning effort we have not attempted to develop separate fire management plans for each alternative. We have utilized the National Fire Management Analysis System (NFMAS) to determine the most cost effective level of protection given the range of outputs and the expected frequency of wildfires. This effort will provide us with an economic basis on which to begin the development of the Fire Management Action Plans for the Forest.

Fuels Management is an activity which varies in extent between alternatives. One of the methods of Fuels Management is to use prescribed fire to dispose of the unwanted residue. The management of fuels affects the management of fire by decreasing the accumulation of residue. This reduction in the volume of fuel available decreases the intensity of wildfires and also changes the characteristics of the fuel bed to the extent that the number of ignitions is also limited.

a. Direct and Indirect Effects of Each Alternative on Fire Management

Fire has played a significant role in the management of the Wenatchee National Forest. It has been a major influence on the ability of the Forest to provide commodities and amenities for the public and it has also influenced how the organization employed to manage the Forest has evolved.

Wildfires will continue to influence the management of the Forest as this plan is implemented. The primary emphasis of this planning effort has been to define the level of protection necessary to provide the outputs defined in the alternatives, and then to seek the most efficient organization to provide that protection

The management practices employed in several resource management disciplines significantly affect how fire will be managed as this plan is implemented. Those interactions are outlined below.

1) The Effects of Recreation on Fire Management

With increased recreational use of the Forest during the summer months there is an increased risk of human-caused fires. This risk depends on the type of activity being pursued and the location of the activity (i.e. off-road-vehicle use has more inherent fire risk than climbing glaciers). However, the occurrence of human-caused fires cannot be correlated to one specific user group. The activity causing the ignition, the location of the ignition, and the timing of ignition are of a random enough nature to cause comparison between alternatives to be, at best, subjective.

Recreational demand is expected to increase under all alternatives. The type of activities which are in vogue, and several cultural factors ranging from the acceptance of smoking to the knowledge of the public, will be the factors which determine how much impact recreational use of the Forest has on the management of fire.

2) The Effects of Wilderness Management on Fire Management

The largest impact of the proposed wilderness management practices is the use of natural ignitions to start prescribed fires within the seven wilderness areas. The reader should refer to Appendix E of the Plan for a detailed review of the wilderness management practices proposed for the Forest. This change is intended to allow fire to play a more natural role in these varied ecosystems. All human-caused fires will be managed as wildfires and an appropriate suppression strategy applied. If any of the prescribed fires exceed the parameters described in the prescribed fire plan for that wilderness, it will be declared a wildfire and suppressed. Examples of these parameters are funding, rate of fire spread, direction of spread, location, and predicted weather patterns.

Another impact of wilderness management on fire management is the need to protect the Class I airsheds associated with the Glacier Peak, Alpine Lakes, and Goat Rocks Wilderness areas from the smoke produced by the prescribed fires outside of these designated areas.

As the wilderness areas are constant through all alternatives, the impacts of these management practices on fire management is constant through all alternatives.

3) The Effects of Timber Management on Fire Management

The alternatives displayed in this plan are composed of differing allocations and management prescriptions. These prescriptions discuss the acceptable management practices for each area. It is the role of fire management to protect these areas efficiently and ensure that changes detrimental to the long-term production of resources do not occur.

Timber management is the primary vegetative management activity that affects fire management. If the debris that is left after a harvest activity is not disposed of, there is an increased chance of destructive wildfires occurring. Utilizing management practices which to some extent replicate the natural role of fire helps maintain a vegetative mosaic that is less susceptible to large, uncontrollable wildfires. Increasing the utilization of woody debris as chips or firewood can also be important to lowering the amount of fuel available. If management objectives can not be met through utilization, and further disposal of the material on the site is needed, prescribed fire is often used. The number of acres on which fuel management activities will occur annually are shown below for each alternative.

ALTERNATIVE	ACRES TO BE TREATED PER YEAR
NC	7,000
A	6,100
B	11,000
C	6,700
D	6,100
E	4,200
F	4,500
G	5,300
H	7,200
I	6,800
J	11,300

Implementation of Alternatives B or J would result in the most acres of fuel treatment. Alternatives E, F and G would result in the fewest acres of post harvest fuels treatment. Alternatives NC, A/NFMA, C, D, H and I would result in a mid-range of acres treated. Treatment of these acres would result in reduced wildfire hazard, but would also increase the potential for wildfire ignition from both industrial activity and slash disposal activities. When all the variables involved in the ignition and potential spread of wildfires are considered, it is not possible to develop a meaningful differentiation between the alternatives in terms of the effects of timber management on the management of fire.

Vegetation management has many facets other than timber management. The Plan will dedicate specific areas to be managed primarily for forage, old growth, riparian habitat, and many other uses. The management practices in each of these areas will affect fire management practices. In each area, the protection criteria will be jointly developed with the resource managers. Prescribed fire will be used as a tool when appropriate.

4) The Effects of Road Management on Fire Management

Road management affects fire management in two primary ways. The road system allows more rapid access for wildfire suppression, and it allows more access to the Forest for public use. This could result in an increased number of ignitions in areas that were previously subject to less intensive use.

For each alternative the sequence of roading by type and amount has been developed. Although there are differences between the alternatives, the impacts of these actions are not expected to significantly affect the implementation of the fire management program.

The reader should refer to Table II-3A in Chapter II of this document for an overview of the Road Management program by alternative.

b. Cumulative Effects of Each Alternative

The cumulative effects of each alternative should be viewed in concert with the management of the intermingled and adjacent lands. The timber on many of the private lands is being rapidly harvested. In some instances, disposal of the resulting slash adjacent to National Forest lands is not occurring. This results in an increased fire hazard. In other areas the private lands are being developed, with a dramatic increase in the number of structures found in the forest environment. These factors influence both the need to implement fuels/vegetation management projects on National Forest lands as well as the strategic decisions which must be made when wildfires occur.

The increasing demands being placed on the Forest to provide a variety of products and recreational amenities results in the fire management task becoming more complex. The cumulative effects will require a more intense effort to protect the Forest from wildfires to ensure the resource outputs described can be attained. It will also require that the fuel management activities be totally integrated into our resource management projects. The use of prescribed fire as one method of fuel management will require in-depth analysis and professional application. This will be of particular importance as we implement our revised wilderness management policies.

The losses and disturbance created by wildfire will continue to be detrimental to the management of the forest regardless of the alternative chosen for implementation.

As the use of the Forest changes so does the combination of ignition sources which result in the wildfires. The dynamic nature of the Forest ecosystems in combination with the shifting patterns of use and variable weather regimes make evaluation of the effects of the alternatives less than accurate. For that reason, it has not been attempted in this narrative.

c. Alternatives' Conflicts with Other Agency Plans and Policies

There are no identifiable conflicts between the implementation of the fire management direction outlined in the preferred alternative and the plans or policies of other Federal, State, or local agencies. As mentioned above, separate fire management plans have not been developed for the other alternatives.

d. Mitigation Measures for Fire Management

Several measures need to be pursued to ensure that the fire management program outlined in this document can be implemented. Specifically the following actions are recommended as being equally effective in all alternatives:

- 1) Continued emphasis must be placed on developing interagency cooperation between all parties involved in wildland fire suppression.
- 2) Fuel management must be integrated into all proposed project activities and must be an emphasis item for our timber harvest program. Utilization must be emphasized.
- 3) Cooperative protection planning must be implemented to provide appropriate protection for Federal, State, and private lands. It is imperative that we work with all county planning commissions and county commissioners in an attempt to improve their understanding of the effects of their decisions on fire management.

4) Continued research into the role of fire in maintaining the various ecosystems found on the Forest must occur.

5) Fire prevention must be integrated into all forest management activities. Private landowners and recreational users must continue to be made aware of the fire hazards and risks involved in outdoor activities.

Additional mitigation measures may be developed on a site specific basis. These activities should be pursued and implemented as appropriate

15. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON SOCIAL/ECONOMIC

a. Direct and Indirect Effects of Each Alternative on Social/Economic

Changes in the levels of Forest outputs have the potential to impact employment and income levels in local communities. Timber harvest levels do vary significantly between alternatives, accounting for the variation in jobs and income between alternatives.

Table IV-27 displays changes in employment and income by alternative in the first decade.

**TABLE IV-27
CHANGES IN EMPLOYMENT AND INCOME BY ALTERNATIVE**

	ALTERNATIVES									
	A/NFMA	B	C	D	E	F	G	H	I	J
Change in Employment (Jobs)	+ 39	+ 577	+203	+279	- 520	- 473	- 225	+ 324	+ 413	+ 630
Change in Income (Million \$)	+0 65	+15 31	+5.14	+7.20	-14 56	-13 30	-6 54	+8 43	+10.86	+16 76

For the first decade, Alternatives C and D would have similar community and social effects. In these alternatives, timber harvest declines slightly from the 1982 base period. There would be some decrease in economic activity related to timber harvest. Other economic activity due to recreation and wildlife outputs would increase slightly.

Visual quality could be decreased slightly from current conditions for Alternative C. The change would be slightly greater for Alternative D. The overall appearance of the Forest would be maintained.

Alternatives B, H, I, and J with their emphasis on the production of commodities, would have community and social effects developing sooner than the other alternatives.

The principal positive effect is the creation or maintenance of jobs in Chelan, Douglas, Kittitas, and Yakima Counties. The metropolitan areas would also benefit from the increased economic activity. However, the altered appearance of the Forest would be a major change from the expected appearance of the Forest for many urban residents. The perceived loss in recreation and visual qualities will have an adverse effect on these users.

The tourist-based communities would also experience an adverse effect based on the perceived loss in recreation and visual qualities. More than the urban areas, these communities would feel the benefits of a healthy economy, and the loss of unroaded recreation opportunities and natural-appearing landscapes. Generally, the older residents of these communities would be more accepting of these changes than the newer residents to whom the recreation opportunities are more important. There would be some breakdown in community cohesion in their outlook on the Wenatchee National Forest.

Many of the positive benefits of Alternatives B, H, I and J will accrue to the rural communities with ties to the wood products industry. Because of increased timber harvest there would be more good paying jobs to contribute to the quality of life in these communities. The leisure aspects of life in these towns would experience an adverse impact due to the change in local environmental

amenities, and changes in recreational opportunities.

The American Indian communities will experience the economic benefits experienced by other communities. There would be adverse effects due to perceived increased risk to cultural sites, risks to anadromous fish, a changed environmental setting of identified cultural sites, and a change in setting of activities identified in treaties.

These alternatives would be the most beneficial to other racial and cultural minorities, principally Hispanic-Americans, owing to their participation in the increased general economic activity in the local area. Similarly, women would benefit from the increased economic activity.

The principal negative effect of Alternatives E, F, and G is the reduction in the number of jobs. The decline in jobs would result in a decline in local economic activity and the related decline in county government receipts. These alternatives would have the most adverse social impacts on racial and cultural minorities (apart from American Indians) and on women.

The negative economic effects of these alternatives would not reach the metropolitan areas. Most urban residents would view the lack of development in a positive light. The effects on the expectations, beliefs, and cohesion would generally be positive.

The loss of jobs and the major social and psychological impacts of unemployment would hurt the rural wood product communities. While some values such as wildlife and visual qualities are improved, the net effect would be substantially adverse. In addition, the apparent "locking up" of productive resources is counter to deeply held values in these communities.

While the preservation of unroaded recreational opportunities and the maintenance of the natural appearance of the Forest are consistent with the values and expectations of tourist-based communities, the conflict between unroaded recreation and resource use will become more apparent and will have the effect of reducing the community cohesion. These communities could experience some of the economic down turn experienced by the wood products-based communities.

American Indian concerns would be alleviated in a large part because of the reduced activity on the Forest under Alternatives E, F and G. Cultural sites and areas relevant to Treaty Rights are generally unaffected, and these alternatives best contribute to their traditional way of life.

b. Cumulative Effects on Social/Economics

Private landowners, the Yakima Indian Nation and the Wenatchee National Forest are major suppliers of sawtimber in the immediate area of the Forest. Local area mills depend on all these sources for timber. Local area employment and income are influenced by the cumulative impact of timber supplied from all these sources.

Major private owners of timberlands have expressed an intention to harvest the remaining sawtimber on their lands within the next 10 to 20 years. The Forest Service attempts to supply a relatively steady flow of timber over time. This may result in large fluctuations in the amount of timber available to local mills over the next few decades. In general, those alternatives with higher harvest levels such as B, D, H, and J would have a lower cumulative effect. Alternative I would have the greatest cumulative effect since it has a higher harvest level for two decades, then drops to long-term sustained yield at the same time that the harvest levels from private lands drop. Alternatives E, F and G would have a cumulative effect in the first decade, but this would decrease thereafter as the area adjusts to the lower harvest level. Alternatives A/NFMA and C are in the middle range of cumulative effects.

16. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON CONSUMERS, CIVIL RIGHTS, MINORITY GROUPS, AND WOMEN

The environmental consequences of the alternatives on American Indian treaty rights and traditional uses of the Forest vary considerably. Each type of Indian use (hunting, fishing, food gathering, religious purposes) may require a different set of environmental conditions to sustain or enhance that use. No single alternative will directly benefit the American Indian community in all situations, nor will it resolve every concern.

Although every alternative would maintain and enhance the resident and anadromous fish habitat on the Forest, there would be differences in the potential pounds of anadromous fish that are available for subsistence and commercial harvest. (A large proportion of this difference would be due to downstream, off-Forest activities, however.) In Alternatives NC, A/NFMA, C, F, G, H, I, and J this potential harvest would be similar to the current situation. There would be little change to the anadromous fish with respect to reserved Treaty rights. In Alternatives B and D, there would be a slight increase in the potential pounds of anadromous fish available for commercial harvest, and in Alternative E, there would be the greatest potential increase. Some of this increase could be attributed to anadromous fish habitat improvements carried out on the Forest under these alternatives.

With respect to hunting and gathering rights, Alternatives NC, A/NFMA, B, D, H, I, and J would likely result in an overall drop in the large game populations due to loss of cover and some problems in forage availability. Conversely, huckleberry production would increase substantially due to the higher level of timber harvest. There would be no overall change in the availability of edible root plants. In Alternatives E, F, and G, there would be an increase in large game cover and forage. As a consequence, large game populations would also increase. With more acres in tree cover, there would be some loss in huckleberry habitat, but no overall change in the availability of edible root plants. In Alternative C, large game cover and forage remain at about current

levels. There would be some increase in huckleberry production, but no overall change in the availability of edible root plants.

The effects of the alternatives on traditional and religious uses of the Forest by American Indians can be assessed by examining the effects on cultural sites and the level of alteration of the natural landscape (generally, pristine environments are favored in religious ceremonies or uses).

In Alternatives NC, B, D, and J there would be substantial modification of the landscape. Timber harvest units and roads would be visible in many areas, detracting from the natural, scenic qualities at those localities. In addition, it might not be possible to manage all significant cultural resources in place. Localities that are culturally sensitive to the American Indians in the Little Naches drainage, in the Clemens and Bald Mountain area, in the upper Rattlesnake, and in the upper Chiwawa and White River drainages would all potentially be affected.

In Alternatives A/NFMA, C, H, and I, 41 percent of the known sites are within management allocations specifying intensive vegetative management. Most sites could be protected in place, but some data recovery might be required where conflicts could not be resolved. In these situations, all information of scientific value would be retrieved. However, some of these sites might represent a physical link between the American Indians and their ancestors. The loss of this attachment could not be adequately mitigated.

Alternatives C and I would also involve the modification of the natural-appearing character of several viewsheds. Of concern to the American Indians would be modifications in the Little Rattlesnake and Little Naches River drainages. Alternatives A/NFMA and H protect or enhance the majority of the important visual areas on the Forest. This would directly benefit ongoing traditional and religious uses of the Forest by the American Indians.

Alternatives E, F, and G have a high emphasis on scenic values, with little predictable impact on cultural sites. These three alternatives would likely enhance American Indian uses of the Forest.

The effects which the varying harvest levels have on employment are discussed elsewhere in this document. A decrease in available jobs, returns to counties, etc., would affect all persons, including minority groups and women.

Indirect but minor effects that would change by alternative are fuelwood availability and housing

Alternatives such as NC, B, D and J have the highest levels of timber harvest. These alternatives also provide more opportunities for wood gathering. Low income families often depend upon Forest residues for heat.

Probably the most significant change between alternatives is in the amount of work in reforestation and timber stand improvement which would be available for women and minority employment. This type of Forest work employs crews that have greater than the average number of minority contractors and employees.

Planting and thinning would decrease for all alternatives except B and H. The least work would be generated under Alternatives E and F. Alternative I would reflect little change from current employment in the first decade but would reduce jobs in the future. Alternatives A/NFMA, C and D all reforest between 3,000 and 5,000 acres per year and thin 3,000 to 4,000 acres per year. These program levels are within the lower range experienced in the past on the Forest. Therefore, those alternatives would have little impact on minority employment.

17. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON PRIME FARMLANDS, RANGELAND, AND FOREST LAND

Farmland

There are no prime farmlands within or adjacent to the Forest. Water from the Forest is used to irrigate orchards, pastures, and farmland in Central Washington, but none of the alternatives significantly affects the quality or quantity of water.

Rangeland

No prime grazing lands have been identified on the Forest. Non-tree vegetative types outside of wilderness contain less than five percent of the total forage acreage. Most of these grassland-shrub types are on the lower dry foothills or river breaks which receive less than 15 inches of annual precipitation.

Forest Land

The average growth rate of timber on the Forest under current conditions is 42 cubic feet per acre per year. There are approximately 120,000 acres that currently produce 85 cubic feet or more per acre per year. It is estimated that under intensive management the number of forest land acres producing 85 cubic feet or more can be increased by 20 to 30 percent. "Prime" forest land is a term used only for non-federal land and does not apply to National Forest lands.

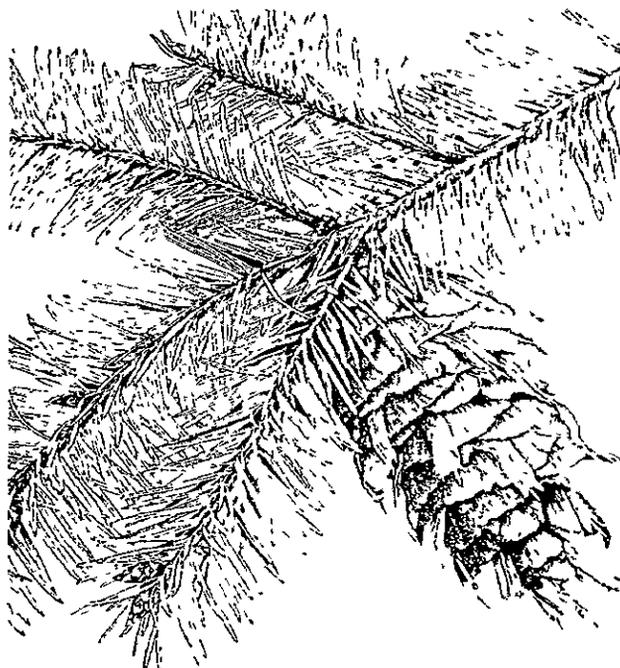

18. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON WETLANDS AND FLOODPLAINS

No significant effects within areas of wetlands and floodplains are anticipated. Adherence to mitigation measures should prevent all but minor and temporary impacts on these sensitive water-oriented areas.

Protection is afforded to these areas through the EW-2 prescription, Best Management Practices, environmental analysis evaluations, and Executive Orders (E.O.'s) 11990 (wetlands) and 11988 (floodplains). These E.O.'s provide direction to ensure that construction of roads, campgrounds, buildings, and other facilities will not have unacceptable adverse impacts on wet-type lands.

Riparian zones are afforded protection through the EW-2 direction along with the Forest's Standards and Guidelines. Protective measures for riparian measures include filter strips, stream channel stability considerations, instream flow maintenance and other resource concerns that are applicable across all proposed alternatives.

Floodplains shall be managed by locating necessary and critical facilities out of the wet areas or by utilizing structural measures to mitigate the impact to acceptable standards.

19. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON THREATENED AND ENDANGERED SPECIES, AND CRITICAL HABITAT

The Endangered Species Act mandates management of threatened and endangered species, therefore, emphasis on these species will have priority over other management objectives. Under restricted funding, threatened and endangered species management will take precedence over other direction and will be accomplished, to the extent possible, at the expense of other needs.

Species on the Forest that are managed under the Endangered Species Act are the Bald Eagle and Peregrine Falcon. The Grizzly Bear and Gray Wolf are being studied for potential recovery on the Forest. If it is decided to recover these species on the Forest then the present direction will be reviewed and adjusted as needed. The environmental consequences of the alternatives on these species are described in conjunction with the Wildlife section of this Chapter.

20. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON ENERGY REQUIREMENTS

Table IV-28 displays the estimated energy impacts of the various alternatives. The energy consumption component encompasses the energy required to produce and utilize Forest resources and to provide services and protection from natural calamities. The energy yields consider direct fuel values, hydroelectric power generation, savings over substitute materials, and savings due to a reduced need for energy expenditure. The net Forest resource energy balance is the difference between the energy produced and the energy expended in utilizing a Forest resource or service.

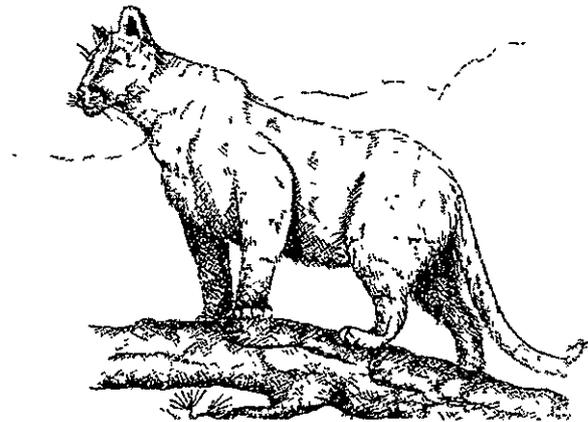

TABLE IV-28

ENERGY BALANCE BY RESOURCE GROUP AND BY PLANNING ALTERNATIVE

1/Energy balance for fuel mineral production is predicted on "proven" deposits. There are no "proven" mineral fuel deposits (economically extractable) presently known to occur on the Wenatchee National Forest. Projected future production is speculative and is dependent upon future energy demand, industry interest and exploration results. Therefore, energy computations for this resource group have not been made.

21. ENVIRONMENTAL CONSEQUENCES OF THE ALTERNATIVES ON URBAN QUALITY; HISTORIC AND CULTURAL RESOURCES; AND THE DESIGN OF THE BUILT ENVIRONMENT INCLUDING THE REUSE AND CONSERVATION POTENTIAL OF VARIOUS ALTERNATIVES

The consequences of the alternatives on Historic and Cultural Resources, and Conservation Potential of the alternatives, are discussed in detail in this Chapter under the Cultural Resource and Energy headings. None of the alternatives has an effect on urban quality or design of the built environment.

C. SUMMARY OF THE RELATIONSHIP BETWEEN SHORT- TERM USES AND LONG-TERM PRODUCTIVITY

The relationship between the short-term uses of man's environment and the maintenance and/or enhancement of long-term productivity is complex. For the purposes of this assessment, short-term uses are those that generally occur on a yearly basis on some area of the Wenatchee National Forest, such as timber harvest as a use of the wood resource, livestock grazing as a use of the forage resource, and recreation and irrigation uses of the water resource.

"Long-term" refers to longer than a 10 year period. Productivity refers to the capability of the land to provide market and amenity outputs and values for future generations. For example, maintenance of long-term soil productivity requires that activities which cause excessive erosion, compaction, and other adverse impacts to soil be mitigated. Occasionally short-term uses will cause substantial damage to isolated areas. Forest direction in Chapter IV of the Land Management Plan contains management requirements designed to protect soil and water resources so that long-term productivity is not significantly impaired.

The Forest Plan establishes a sustained yield of resource outputs while maintaining productivity of resources. The specific direction and mitigation measures included in the Forest-wide direction ensure that long-term productivity will not be impaired by the application of short-term management practices.

Each alternative except NC was analyzed to assure that Forest direction could be met. An alternative was revised if some aspect did not meet these requirements. Thus, long-term productivity is assured in every alternative.

A discussion of how various environmental components can affect the long-term productivity of the Forest is presented in the next few pages.

Recreation uses such as developed campgrounds, ski areas, recreation residences, and wilderness, all represent long-term commitments of the land. These commitments, in some cases, can mean a loss of long-term productivity of other resources. Heavy, short-term recreation uses such as large group outings or concentrated use in popular areas may also result in a reduction of productivity. For example, campsites and trails can be compacted by heavy use which may result in soil and vegetation damage. The short-term use of a campsite in a fragile wilderness ecosystem can result in a long-term loss of vegetation. Recreation use in critical fish habitat areas has the potential to affect the genetic make-up of fish populations by reducing the wild-type genes which may be necessary for the long-term maintenance of a fish species.

Cultural resources represent a long-term use of the land. In many cases, the resources have been in place for decades or even centuries. However, these resources generally occupy a small area of land (average site on the Forest is less than one acre in size) and thus have a negligible effect on the long-term productivity of the area they occupy.

Short-term vegetation management practices can have a long-term effect on the maintenance of scenery. Timber harvest with its associated road construction will lead to greater visual diversity in the forest stands but also will contribute to the loss of the "natural-appearing" setting. Natural-appearing landscapes are preserved in wilderness and roadless area allocations.

A measure of long-term productivity for the fisheries resource is the effect on stream habitat capability. It is not anticipated that there will be any losses of this capability with implementation of any of the alternatives (see Chapter IV on Fish, including the mitigation section). Overfishing streams can have negative effects, as detailed earlier. Those alternatives with the most roading and access into wild fish producing streams would have the greatest potential for this effect. The possible reductions in the long-term productivity of the wild fish species should be roughly proportional to the increase in fishing due to roading. However, it is anticipated that the net losses would be insignificant.

Short-term management of the tree resource will have effects upon long-term productivity depending on the intensity of management selected. All alternatives would increase projected per-acre productivity during the next 50 years. The amount of this increase is shown below by alternative.

TABLE IV-29
TIMBER PRODUCTIVITY INCREASE BY ALTERNATIVE 1/

	A/NFMA	B	C	D	E	F	G	H	I	J
Productivity by year 2030 in cubic feet per acre per year	33	42	32	33	30	31	35	43	36	37
Increase in productivity in percent	+14	+46	+12	+14	+3	+7	+22	+47	+24	+26

1/ Figures are not available for the NC alternative.

Average net growth on the Forest's existing timber stands is 29 cubic feet per acre. Short-term management techniques which will increase the long-term productivity include the planting of genetically superior trees. This can account for about 10 percent of the yield increase. An additional 10 percent of the yield increase can be achieved through thinning of the stands. Another 30 percent could be gained through prevention of disease and insect losses. Approximately 50 percent more yield could come through harvest of the trees at the culmination of their growth rather than allowing the trees' growth to slow down and stagnate. And finally an extra seven percent, or 2,000 board feet per acre, can be obtained through fertilization. This is based upon a 1979-1984 study of fertilization plots to determine the increase in growth resulting from the use of fertilization.

Long-term productivity of forage on the Forest will be little affected by short-term grazing of livestock. Without grazing use, some areas will become tree covered or have some shrub types grow out of reach of grazing animals, including wildlife. Grazing by livestock can help the nutrient recycling process, particularly in drier vegetative types where natural decomposition of dead

organic material is very slow. Trampling action by grazing animals help sow seeds beneath the litter layers thereby enhancing reproduction of grasses and other vegetation.

Background water yield on the Forest is assured for short-term uses as well as long-term productivity. Vegetation management activities on the Forest can provide for some water yield increases. Thus, Alternative B provides the maximum water yield increase while Alternative E affects water yield increases the least. Under all alternatives, timber harvesting operations will be designed to insure the short-term and long-term maintenance of water quality.

The soil resources are affected by most management activities. Activities such as timber harvest, road construction, and use of developed recreation sites, are cumulative and have long-term effects on the productivity of the soil. These effects can be seen through both soil erosion and soil compaction. Soil compaction is generally considered to be a long-term effect. However, on some types of clayey soils, the processes of wetting and drying (shrink/swell) tend to break up the compaction over several years.

The long-term quality of air is not expected to be degraded by short-term events or uses. These events could be wildfires, prescribed fire, or use of vehicles. It is likely that the quality of air moving onto the Forest from prescribed burning by State, Federal, and other agencies to the west will have a greater effect than air pollution generated on the Forest itself.

Mineral resources are not renewable and deposits are fixed in size and grade. Forest Service policy as it relates to exploration and development of mineral resources does not change by alternative. Therefore, the short-term/long-term relationship does not vary by alternative. However, management prescriptions which call for withdrawing lands from mineral entry have a short-term effect on minerals' availability. This can have a long-term effect if withdrawn indefinitely. Examples of areas withdrawn include wilderness areas, research natural areas, developed recreation sites, and some special interest areas and scenic travel routes.

Arterial and collector roads, and some local roads and landings, are dedicated uses that take land out of production. Therefore, these kinds of uses have long-term effects. These effects vary because they are directly related to the amount of timber harvested. Roads can have indirect effects on long-term productivity of fish and wildlife by increasing the amount of recreational fishing and hunting use. Long-term productivity of timber can be increased due to roads allowing access for more intensive management activities. Long-term effects of roads on the soil resource and on water quality can also be significant.

Forest and range wildfires are short-term events. In the natural environment, they occur on a cyclic basis and do not affect the long-term productivity of the land. In the short-term, both the wildfire itself and fire suppression activities can affect productivity by altering plant succession, productivity, and diversity; fuel accumulations; nutrient cycles and energy flow; stability of ecosystems; and air quality.

Major transmission line corridors which cross the Forest are essentially long-term commitments of the land within the corridors. While the types of use may be limited, the long-term productivity of the land is not lost. Growing sawtimber, for example, would not be compatible but growing forage for livestock and wildlife would be.

Small hydroelectric projects are, by their nature, long-term uses. Long-term productivity is thereby closed on areas being inundated or occupied by above-ground conduits.

D. SUMMARY OF IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

An "irreversible commitment of resources" results from a decision to use or modify resources that are renewable only over a long period of time, such as soil productivity, or non-renewable resources such as cultural resources or minerals. An "irretrievable commitment of resources" refers to resource production or the use of a renewable resource that is lost because of land allocation and/or scheduling decisions. In other words, opportunities are foregone for the period of time that resource cannot be used. The proposed Forest Plan and the alternatives examined were all based on the principles of multiple-use and long-term productivity for all resources. Measures to protect natural resources that could be irreversibly affected by management practices were incorporated into Forest-wide Standards and Guidelines (see Chapter IV of the Forest Plan).

The major irreversible and irretrievable resources on the Wenatchee National Forest are the roadless areas. The development of roadless areas would mean an irreversible loss of the characteristics which qualify these areas for wilderness or roadless areas. Development could also mean an irreversible loss of natural scenery and, in some cases, old growth habitat. On the other hand, not developing roadless areas may be an irretrievable loss of opportunities for vegetation management. This could result in lower volumes of timber harvest and forage being produced on the Forest.

The protection of cultural resources also may affect timber production. This effect would be relatively small, however. Trees on and near cultural sites may not be harvested or may be harvested at less than maximum intensity. Since the commitment to protect these cultural resources will continue in the foreseeable future, the timber not harvested on these sites represents an irretrievable loss of that resource.

Another irretrievable loss of timber would be those stands occurring in designated wilderness or dedicated as old growth wildlife habitat. Insects, disease, and fire can also cause irretrievable losses.

Commitments for grazing cattle on the Forest are based on a term permit system which is a privilege to livestock owners. This is not an irretrievable commitment if unacceptable resource damage occurs or terms of the permit are violated.

Under Alternative C, unique ecosystem classifications would not be proposed for all possible areas (see the *Vegetation* section in this chapter for a list of the areas). This may mean an irreversible loss of the opportunity for classification. For example, the Camas area was proposed as a Botanical Area for protection of *Delphinium viridescens*, Wenatchee Larkspur. The area would not be classified but the plant would be protected through the Forest Plan Standards and Guidelines. Similar effects would occur to the other proposed Botanical Areas. Geologic features in proposed Geologic Areas would not be irreversibly lost even though they would not be designated.

The water resource on the Forest fluctuates in runoff or output in response to changes in climate. Water quality and timing of runoff is affected by management activities. These effects are rarely irreversible with degradation being only temporary over time.

Soil productivity can be irreversibly lost or reduced by dedicated uses of the land. Examples of these uses would be arterial and collector roads, administrative sites, and developed recreation sites. Soil erosion, as a result of management activities, is an irreversible loss because once the soil particles are removed from the site and deposited into a stream or river, they are no longer available. Accelerated erosion rates can reduce soil productivity and also reduce the water holding capacity of the soil.

Removal of mineral or energy resources is an irreversible commitment of resources. The removal and utilization of rock resources for road construction would be an example of a common use on the Forest. Actual commitment of mineral resources will depend upon demand and mining industry initiative.

There are no known irreversible and irretrievable commitments of resources affecting fisheries or air quality involved in the implementation of the preferred alternative.

E. SUMMARY OF PROBABLE ADVERSE ENVIRONMENTAL EFFECTS THAT CANNOT BE AVOIDED

Implementation of the preferred alternative on the Wenatchee National Forest will result in some adverse environmental effects that cannot be avoided. The degree of severity of the adverse effects can be minimized by adhering to the direction in the management prescriptions and Forest-wide Standards and Guidelines in Chapter IV of the Forest Plan, but some impacts generally cannot be avoided if any management activities occur.

Development and use of recreation sites would have several adverse effects. These effects include: compaction of soil, vegetative damage, water pollution, noise and dust from motorized use, disturbance of game animals and their habitat; and localized air pollution from campfire smoke and vehicle exhaust.

It is likely that some significant cultural resource sites will inadvertently or unavoidably be disturbed or destroyed by management activities. This would be especially true for subsurface sites that cannot be located through surface surveys. Even with mitigation, unanticipated or unavoidable disturbances can result in the loss of cultural values that might otherwise be available for future enhancement or research uses.

Vegetation management activities, particularly timber harvest, have several unavoidable adverse effects. The most conspicuous of these is the effect on scenery. Visual quality can be lowered by timber harvest on steep slopes that are highly visible from recreational travel routes. Burning of harvest units will also affect the visual quality for a short time. These adverse effects will eventually be reduced by the regrowth of the vegetation. Other impacts on

the natural appearance of the landscape would include roads and structures which would be apparent despite efforts to carefully blend them with the landform.

Timber harvest activities would also have adverse effect on water quality and soil. Water quality effects would be short-term within riparian zones and wetlands. Soil effects are more long-term due to road construction and reconstruction associated with timber harvest. Road construction disturbs and displaces soil but is a necessary activity that needs to be carried out in order to harvest trees and carry out other management activities. Management can have an effect on how the activities are carried out, as well as the scheduling. Both the technique and the scheduling can affect the kind and amount of impact that can occur on the soil and water resources.

Livestock use of the forage component may cause some stream bank trampling with increases in sediment and fecal coliform in the streams. There may also be some displacement of wildlife by livestock due to the social behavior between them and minor competition for forage or space.

Because mineral development on open public land is a right under certain conditions, unavoidable adverse effects on other resources will occur. Predicting where these impacts will occur and the scope of these impacts depends upon the location and type of activity proposed. Since this activity is proposed by the public rather than by the Forest Service, identification of the unavoidable environmental effects will be done when an operating plan is received and an environmental analysis of the proposal is made.

Wildfires can cause loss of soil, wildlife habitat, vegetation, structures, and can increase the potential for flooding. The possibility of these adverse effects always exists. However, the proper treatment of fuels will result in a gradual reduction and breakup in the continuity of natural residues. This would tend to reduce the occurrence of large wildfires in the long-term. The smoke from wildfires and prescribed fire will have a short-term adverse effect on the air quality.

The clearings for utility corridors, with the multiple steel and wood towers, have unavoidably modified the landscape in the areas where they occur. The need to maintain the corridors in a "clean" condition assures that the unnatural appearance will continue. On the other hand, soil displacement and any effects on water resources within the existing corridors have long since stabilized.

Construction of the one identified potential utility corridor would result in modification of the visual quality for a long time. During the construction phase, there would be some soil disturbance, some possible effect on water quality, and some possible disruption of wildlife patterns. These effects can be mitigated, with the adverse effects on all but the visual quality and some types of recreation being of short duration.

Any of the proposed small hydroelectric projects which reach the construction stage will result in some adverse environmental effects. Impacts to soil and water will occur to some degree. Construction techniques and mitigation measures can minimize most impacts and limit them to the construction effects on the visual resource. Some projects will also have long-term impacts on wildlife and recreation. This is particularly true of those projects which require large structures, such as large diameter, above-ground penstocks of several miles in length.

F. ENVIRONMENTAL CONDITIONS UNCHANGED BY THE ALTERNATIVES

1. Wilderness

The land area designated as wilderness is the same in each alternative. Within wilderness the physical and biological environmental conditions would remain unchanged between alternatives.

Wilderness has a special relationship to fish and wildlife. Since two goals of wilderness are to preserve wilderness character and to preserve their natural conditions, the maintenance of genetic diversity is assured. In all alternatives, this maintenance of the existing fish and wildlife populations is similar because the quantity of wilderness does not vary.

Planting of fish species into previously stocked lakes, as long as native species are used, is still usually allowed. The Forest Service will continue to coordinate with the Washington Department of Game and user groups to be sure that stocking is conducted in a manner to preserve the inherent qualities of the wilderness.

Wilderness also has a benefit in assuring the long-term supply of high quality water runoff in streams. Again, since the quantity of wilderness will not vary by alternative, the quality of the water inhabited by fish both in the wilderness and downstream will not change.

2. Alpine Lakes Management Unit

The environmental conditions and effects within the Alpine Lakes Management Unit do not vary by alternative. In all alternatives the land use allocations within the Alpine Lakes Management Unit are the same as those in the Alpine Lakes Area Land Management Plan FEIS of November 2, 1981.

3. Research Natural Areas

Environmental conditions and effects on the Thompson Clover and Meeks Table Research Natural Areas will be the same in each alternative. These Research Natural Areas were established by the Chief of the Forest Service and will receive equal protection in all alternatives.

4. Entiat Experimental Forest

The Entiat Experimental Forest was formally designated by the Chief of the Forest Service in 1971. The Entiat Experimental Forest occupies the same land area and is managed under the same management prescription (EF-1) in all alternatives.

5. Utility Corridors

Existing Corridors: These corridors do not vary by alternative. Each alternative proposes that they continue basically as they exist today. Some upgrading of corridors is anticipated in all alternatives. For instance, a 115 KV line might be increased to a 230 KV line.

Proposed Corridors: The Western Regional Corridor study for the State of Washington identified one proposed corridor crossing the Wenatchee National Forest. This corridor, if built, would utilize a "window" in the Cascade Mountains in the area from about Tacoma Pass to Pyramid Peak. The corridor itself would then run southeasterly across the Forest toward the Hanford Reservation/Tri-Cities area. The study projected this corridor for the period 1990-2020. This proposal is identified in all alternatives.

6. Small Hydroelectric Projects

The opportunity for small hydroelectric projects varies only slightly from alternative to alternative. Generally it is assumed that those alternatives which allocate the most acres to roading and other surface disturbing activities will provide the best opportunities for small hydro development. This is attributed to the existence of road access which would lower resistance to proposed projects.

However, the range of probable small hydro projects across all alternatives is quite small. In the existing situation (Alternative A/NFMA) the Forest has 25 projects proposed. Twenty-two of these are in the feasibility study stage. Only three have resulted in applications to build small hydroelectric projects.

It is estimated that a maximum of 40 projects could be proposed and move to the feasibility study stage. But only four would proceed to the stage of applying for a license to build and operate a project. Thus, there is little difference in the effects of this activity between alternatives.

LIST OF PREPARERS

The following is a list of Forest Interdisciplinary (ID) Team and Forest Management Team members who participated in the Forest Plan development. Their qualifications (position, education and experience) and their responsibilities for preparing the Final Environmental Impact Statement, including significant methodology and analysis, is indicated.

O'NEAL, SONNY Forest Supervisor

Education: B.S. Forest Management, University of Arkansas at Monticello.

Experience: Twenty-three years experience with the Forest Service in Utah, Idaho, Wyoming and Washington Forest Service line officer positions have included Forest Supervisor, Deputy Forest Supervisor, District Ranger positions. Forest staff positions have included Planning, Timber, Lands, Recreation, Minerals, Fire and Manpower Member of Management Team which participated in all facets of plan development.

FERGUSON, LAURA Deputy Forest Supervisor

Education B.S. Landscape Architecture, W. Virginia University, 1969.

Experience: Seventeen years with the Forest Service in landscape architecture, recreation, Forest Planning, State-wide Forest Resource Planning, Federal Liaison, and District Ranger. Member of Management Team which participated in all facets of plan development.

BICKFORD, L. MONROE Forest Silviculturist

Education: B.S. Forest Management, Washington State University, 1962
M.F. Silviculture, Oregon State University, 1964.

Experience: Twenty-six years experience with the Forest Service in the Pacific Northwest Region, primarily in timber management but including brief periods in research and other resource activities. Member of the ID Team since 1979. Provided timber management input for the Forest Plan. Developed timber yield tables and analyzed the effects of the alternatives on the timber resource.

CARTER, SUSAN Archaeologist

Education: B.A. Anthropology, University of Washington, 1973.

Experience. Twelve years experience with the Forest Service as a Cultural Resource Specialist on the Mount Baker-Snoqualmie and Wenatchee National Forests. Member of the Interdisciplinary Team from 1981-1988. Primarily responsible for accumulating, evaluating, and providing cultural resource data for the Forest Plan Analyzed the effects of the alternative on the cultural resource Also updated the Wild and Scenic River portions of the FEIS and Forest Plan.

CHRISTENSEN, WAYNE C., P.E. Engineer

Education: B.S. Degree Civil Engineering, Utah State University, 1963.

Experience: Three years with Federal Highway Administration at various locations throughout the country. Twenty-three years with the Forest Service in Intermountain and Pacific Northwest Regions. Assignment in various engineering areas, primarily in road planning design and construction. Member of Management Team which participated in all facets of plan development.

EDWARDS, RICK Hydrologist

Education: B.S. Aquatic Biology; M.S. Forest Engineering (Forest Hydrology / Aquatic Ecology)

Experience: Ten years experience with the Forest Service. Member of ID Team since 1988. Worked on preparation of Soil and Water, Riparian Area and Fish Habitat resource information for the FEIS and Forest Plan in cooperation with other members of the ID Team.

GLASS, PHILLIP D. Recreation Staff Officer

Education: B.S. General Forest Management, North Carolina State, 1959.

Experience: Twenty-nine years experience with the Forest Service--22 years in the Intermountain Region and 5 years in the Pacific Northwest Region. Project Forester for four years, Assistant District Ranger for 4 years, on four Ranger Districts for 14 years, Recreation Staff Officer for 7 years. Member of the Management Team which participated in all facets of the plan development.

HART, PAUL R. JR. Forest Public Affairs Officer

Education: B.A. Political Science, Central Washington University, 1967.

Experience: Fifteen years experience in Forest Service public involvement and public information work. Five years experience as reporter and photographer for daily newspapers. Member of the Management Team which participated in all facets of plan development.

**HEATH, MONTY Assistant Recreation Staff
Wilderness and Recreation Program Coordinator**

Education: B.S. Forest Management, University of Washington, 1974.

Experience: Fifteen years with the Forest Service with 11 of those years in Wilderness and Recreation Management. Member of the ID Team since 1987. Provided Wilderness and Recreation planning data and analysis for the Forest Plan

HOFFMAN, GLENN Forest Planning Staff Officer

Education: B.S. Forest Management, Washington State University, 1966.

Experience: Twenty-two years total experience with the Forest Service in the Pacific Northwest Region with 13 years on the Wenatchee National Forest. Areas of experience include timber management, land management planning, and administration. Lake Wenatchee District Ranger 1980-1987 and served as member of Management Team which participated in all facets of plan development. Planning Team Leader since 1987 Responsible for coordinating and directing the interdisciplinary team's efforts in completing the Forest Plan and associated environmental documents.

JONES, PHILIP J. Range Specialist / Planner

Education: B.S. Forestry-Range Management, University of Montana, 1961

Experience: Twenty-seven years experience with the Forest Service in the Northern and Pacific Northwest Regions with main responsibilities in resource management Member of the I.D Team since 1981. Responsible for providing range and NEPA compliance input for the Forest Plan. Analyzed the effects of the alternatives on the range resource.

KELEMAN, BRUCE A. Fire, Air Resouce Planning

Education: B.S. Renewable Natural Resource Management, University of California, Davis Campus, 1972

Experience: Twenty years experience in fire management assignments on four National Forests in three states Have served on several Regional Fire planning groups and is currently on the National Fire Management Analysis Work Group. Provided Fire and Air Resource management input for the Forest Plan

LACABE, LARRY Transportation Planner

Experience: Twenty-five years experience with the Forest Service including transportation planning and land and resource planning. Member of the I.D Team since 1980 Provided road inventory data for the Forest Plan Analyzed the effects of the alternatives on the transportation system.

LILLYBRIDGE, TERRY Botanist/Ecologist

Education: B.S. Range Management, Washington State University, 1974
M.S. Forest and Range Management, Washington State University, 1976.

Experience: One year Soil Conservation Service soil scientist Two years Soil Conservation Service range conservationist. Ten years Forest Service plant ecologist and botanist. Member of Interdisciplinary Team since 1988 Provided input on threatened and endangered species, old growth, Research Natural Areas, and biological diversity

LOWERY, BILL District Ranger, Cle Elum

Education: B.S in Forestry

Experience: Thirty years Forest Service in Region 6. This includes 21 years as District Ranger on two Ranger Districts and two National Forests Other experiences include positions as District Timber Management Assistant, Fire Control, and Recreation Assistant. Member of Management Team which participated in all facets of plan development

MACDONALD, KENNETH D. North Zone Fish Biologist

Education: B.S Fisheries Science, Oregon State University, 1977
B S. Forest Management, Oregon State University, 1981

Experience: Eight years with the Forest Service as a Fish Biologist providing input to timber sales and other resource activities, as well as habitat assessment, improvement and monitoring. Member of Interdisciplinary Team since 1988. Prepared Forest-wide standards for fish and for the riparian prescription

MAEKAWA, HENRY Landscape Architect

Education: B.S. Agriculture, Colorado State University, 1965.
Masters Landscape Architecture, University of Oregon, 1970.

Experience: Nineteen years experience with the Forest Service as a Landscape Architect on the Deschutes and Wenatchee National Forests. Member of the I.D. Team since 1979. Primarily responsible for providing visual resource data for the Forest Plan. Analyzed the effects of the alternatives on the visual resource.

MALONE, JOHN Forest Timber Harvest Specialist

Education: B.S. Forestry - Logging Engineer, Oregon State University, 1958

Experience: Twenty-five years experience with the Forest Service in the Pacific Northwest Region, primarily in timber management. Provided timber harvest system information for the Forest Plan.

MARVIN, SUSAN Forest Archaeologist

Education: B.A. Anthropology, Northwestern University 1972.
M A. Antrhology, Washinton State University 1978.

Experience: Fifteen years as an archeologist, the last eight years as a Cultural Resource Specialist for the Forest Service. Member of the Interdisciplinary Team since 1988. Updated cultural resource management data for the FEIS and Forest Plan.

McCUTCHEN, EDWIN L. Range, Wildlife, and Watershed Officer

Education: B.S. Forest-Range Management - 1962, Colorado State University.

Experience: Twenty-five years experience with the Forest Service (17 years in the Southwest Region and 8 years in the Pacific Northwest Region). Primarily responsible for range, wildlife, fish, soil and watershed management programs on the Wenatchee National Forest for last 9 years. Previous assignments were 7 years as District Ranger on the Luna Ranger District, Gila National Forest and 3 years as the District Ranger on the Wilderness Ranger District, Gila National Forest. Provided functional information, review and editorial comment for range, wildlife, watershed, soils, fish, and threatened, endangered, and sensitive species sections of the Forest Plan. Member of Management Team which participated in all facets of plan development.

MCCOLLEY, PHILLIP Soil Scientist

Education: B.S. General Agronomy, Washington State University, 1958

Experience: Twenty-eight years experience as a Soil Scientist; 15 years with the Wenatchee National Forest and 13 years with the Soil Conservation Service. Member of the I.D Team since 1979. Primarily responsible for providing soil resource input for the Forest Plan Analyzed the effects of the alternatives on the Forest's soil resources

MORTON, STEPHEN L. District Ranger, Leavenworth

Education: B.S. Forest Management, 1965, University of Minnesota/M.S. in Forestry (Rec.) University of Minnesota, 1967.

Experience: Twenty-two years experience with the Forest Service in Forest resource management. Served on five National Forests. Since 1981 have been District Ranger of the Leavenworth Ranger District. Primarily responsible for providing information, analysis, and evaluation of alternatives, with special concentration on the Leavenworth District. Member of the Management Team which participated in all facets of plan development

MURPHY, AL District Ranger, Chelan

Education: B S. Forestry, University of Montana, 1974.

Experience. Fifteen years experience with the Forest Service in the Southwest, Intermountain, and Pacific Northwest Regions. Positions have included fire management, timber, minerals, recreation, and range Member of Management Team which participated in all facets of plan development.

MURPHY, PATRICK M. Writer/Editor, Data Base Manager

Education. B S. Forest Management, Washington State University, 1977.

Experience: Eleven years experience with the Forest Service on the Wenatchee National Forest in wilderness, silviculture, and planning. Two years experience with the Bureau of Land Management in wilderness inventory. Writer/Editor since 1985, R2 Map manager since 1986.

O'CONNOR, DANIEL M. Graphics Specialist

Education: A.A. Technical Illustration, Clover Park Technical Institute, 1988

Experience: Eight years experience on Wenatchee National Forest; Wilderness Ranger, and other experience includes fire and timber management, graphics and desktop publishing for planning documents

PAYNE, GROVER G. Fire Management Officer

Education: B.S. Forestry, University of Georgia, 1965.

Experience: Twenty-six years experience with the Forest Service in Southwest, Southern, and Pacific Northwest Regions, primarily in timber management, recreation and resource management, state and private forestry, aviation and fire management, public affairs and National Forest administration (District Ranger). Member of Management Team which participated in all facets of plan development.

PHILLIPS, CHARLES A. Forest Wildlife Biologist

Education: B.S. Zoology, Southern Oregon College, 1967.

Experience: Twenty-one years with the Forest Service. District level work included 2 years in fire control, 7 years in timber, and 2 years as wildlife biologist. Have been a Forest wildlife biologist for 10 years on two National Forests. Provided threatened, endangered and sensitive species, big game species, indicator species, and wildlife range information for Forest planning.

POZZUTO, GEORGE District Ranger, Lake Wenatchee

Education: B.S. Forest Management, University of Maine, 1970

Experience: Eighteen years with the Forest Service. Served ten years as Forest Planning Team Leader on the Olympic National Forest. Led process for the Wild and Scenic River suitability study on the Wenatchee. Member of Management Team which participated in all facets of plan development.

ROTELL, DONALD F. District Ranger, Naches

Education: B.S. Forest Management, Pennsylvania State University, 1960

Experience: Ten years experience District Ranger in Pacific Northwest. Fifteen years experience in timber, land adjustments, recreation management. Member of Management Team which participated in all facets of plan development.

SIMMONS, JOHN D. Area Minerals Specialist

Education: B.S. Geology, Western Washington State University, 1973. Graduate Studies - Geology, WWSU, 1973/74.

Experience: Four and one-half years experience with the Forest Service in the Pacific Southwest and Pacific Northwest Regions and six years experience with the Bureau of Land Management in California, Montana, North Dakota, and South Dakota as a district, zone and area mineral specialist. Member of the I.D. Team since 1985. Primarily responsible for providing minerals data for the Forest Plan. Analyzed the effect of the alternatives on the mineral resources.

STEBLINA, VLADIMIR I. Forester/Economist

Education: B.S. Forestry, University of California at Berkeley, 1972. Graduate Studies, University of California at Berkeley, 1976-1977.

Experience: Eight years experience with the Forest Service primarily as a Planner/Economist. Two years experience with Forest Service as Recreation Planner. Two years experience with Bureau of Land Management as Forester/Recreation. One year as Environmental Specialist with National Park Service. Two years consulting firm as a Forester. Member of the I.D. Team since 1985. Provided and analyzed resource and economic data for the Forest Plan.

VANDERLIN, ORVILLE Assistant Staff Officer, Lands and Minerals

Education: B.S. Forest Management, Michigan Technological University, 1959.

Experience: Twenty-four years experience with the Forest Service in engineering, timber, recreation, lands and minerals. Member of the I.D. Team since 1980. Analyzed the effects of the alternatives on lands, and utility corridors.

WALK, FRED O. Timber Staff Officer

Education: B.S. Forest Management 1961, Iowa State University.

Experience: Twenty-nine years in R-6, primarily in timber management and resource management. Four years line officer (District Ranger). Member of Management Team which participated in all facets of plan development

WHITEHALL, KARIN District Ranger, Entiat

Education: B.S. College of Forestry, Colorado State University, 1975

Experience: Fifteen years with the Forest Service in forest management and wildland hydrology. Member of Management Team which participated in all facts of plan development.

Development of the Forest Plan and FEIS required the support and assistance of the entire National Forest staff over an eight year period. The following persons, in addition to the current preparers, also provided significant contributions:

Anderson, Carl F. Entiat District Ranger, 1981-1984. Interagency planning Liaison 1984-1986.

Croyle, Carmen Visual Information Assistant, 1980-1986.

Heath, Gerald Deputy Forest Supervisor, 1984-1987.

Hetzer, Robert Chelan District Ranger, 1976-1987.

Hohisel, Neal Recreation Specialist, 1979-1987

Kessler, Steven Fisheries Biologist, 1983-1987.

Krzak, Joan Economist, 1981-1983.

Kuiper, Orville Fire Management, 1981-1985.

Lambert, Daniel Cartographic Aid, 1981-1984.

Lyon, Donald Forest Planner, 1980-1986.

Meschter, Daniel Mining Engineer, 1980-1984.

Opdycke, James Timber Planner, 1979-1983.

Pederson, Robert FORPLAN Specialist, 1979-1986.

Rhodus, Gran Forest Hydrologist, 1980-1985.

Roberts, Rick Wildlife Biologist, 1982-1986

Salinas, Joe M. Entiat District Ranger, 1985-1987.

Smith, Donald H. Forest Supervisor, 1980-1987.

Thompson, Allen Engineering Staff, 1983-1988.

Tiedemann, Roland K. Planner, Writer/Editor, 1979-1985.

Wilson, Thurman Economist/Analyst, 1984-1985.

Wischnofske, Merle Wildlife Biologist, 1979-1982.

GLOSSARY

ACRE EQUIVALENT - When applied to habitat improvement or improvement structures this term reflects overall habitat benefits derived. It reflects the zone of influence of the habitat improvement for the target species. For example, a single water development for upland game birds occupies very little space but has an acre equivalent of 160 because it serves 160 acres of bird habitat. A single water structure for big game has a value of 640 because it has a larger zone of influence for the more mobile big game animals.

ACRE-FOOT (AF) - A water measurement term equal to the amount of water that would cover an area of one acre to a depth of one foot (43,560 cubic feet).

ACTIVITY - Actions, measures, or treatments undertaken which directly or indirectly produce, enhance, or maintain forest outputs and rangeland outputs, or achieve administrative and environmental quality objectives. Forest Service activity definitions, codes, and units of measure are contained in the Management Information Handbook (FSM 1309 11).

AIRSHED - A geographical area that, because of topography, meteorology, and climate, shares the same air

ALLOCATED FUNDS - Funds from sources other than Congressionally appropriated funds. Allocated funds include the Senior Community Service Program, brush disposal (BD), Knutson-Vandenberg cooperative deposits (K-V), and State of Washington funds for trails from the Interagency Committee for Outdoor Recreation

ALLOWABLE SALE QUANTITY (ASQ) - The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan for a time period specified by the plan. This quantity is usually expressed on an annual basis as the "average annual allowable sale quantity" (36 CFR 219 3).

ALTERNATIVE - One of several policies, plans, or projects proposed for decision making

AMENITY - An object, feature, quality, or experience that gives pleasure or is pleasing to the mind or senses. Amenity value is typically used in land use planning to describe those resource properties for which market values (or proxy values) are not or cannot be established.

AMS - An abbreviation of Analysis of the Management Situation.

ANADROMOUS FISH - Those species of fish that mature in the ocean and migrate into streams to spawn. Salmon, steelhead, and shad are examples

ANALYSIS AREA - A delineated area of land subject to analysis of (1) responses to proposed management practices in the production, enhancement, or maintenance of forest and rangeland outputs and environmental quality objectives and (2) economic and social impacts

ANALYSIS OF THE MANAGEMENT SITUATION (AMS) - A determination of the ability of the planning area to supply goods and services in response to society's demand for those goods and services

ANIMAL UNIT MONTH (AUM) - The quantity of forage required by one mature cow (1,000 pounds), or the equivalent for one month, based upon average daily forage consumption of 26 pounds of dry matter per day (800 pounds/month).

APPROPRIATE SUPPRESSION RESPONSE - The planned strategy for suppression action (in terms of kind, amount, and timing) on a wildfire which most efficiently meets fire management direction under current and expected burning conditions. It may range in objective from prompt control to one of containment or confinement.

APPROPRIATED FUNDS - Funds from the U. S Treasury, which Congress has authorized the Forest Service to obligate This is the sum of operational, capital investment, and backlog costs.

AQUATIC ECOSYSTEMS - Streams, channels, lakes, marshes or ponds, and the plant and animal communities they support.

ASQ - An abbreviation of Allowable Sale Quantity.

AREA OF SPECIES MANAGEMENT GUIDES - A contiguous area where management direction is the same

ARTERIAL ROADS - See Roads.

AUM'S - An abbreviation of Animal Unit Months.

BACKGROUND - In visual management terminology, refers to the visible terrain beyond the foreground and middleground where individual trees are not visible but are blended into the total fabric of the forest stand (also see Foreground and Middleground).

BASAL AREA - The cross-sectional area of a stand of trees measured at breast height. The area is expressed in square feet.

BASE TIMBER SALE SCHEDULE - A Timber Sale Schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and this planned sale and harvest for any decade is not greater than long-term sustained yield capacity. (36 CFR 219.3)

BASIN - The largest regional hydrologic unit for the Wenatchee National Forest (Columbia River Basin).

BENCHMARK LEVELS - The outputs and costs for managing the Forest at certain levels of management so that a comparison could be made on costs, values, and effects.

BENEFIT - (Value) Inclusive terms used to quantify the results of a proposed activity, program or project expressed in monetary or nonmonetary terms.

BENEFIT-COST RATIO - Measure of economic efficiency computed by dividing total discounted primary benefits by total discounted economic costs.

BEST MANAGEMENT PRACTICES (BMP's) - A practice or combination of practices determined by the state that are the most effective and practical (including technological, economic and institutional considerations) means of preventing or reducing the amount of pollution generated by non-point sources to a level compatible with water quality goals.

BF - An abbreviation of board feet

BIG GAME - Those species of large mammals normally managed for sport hunting

BIOLOGICAL CONTROL - A method to control wildlife or insect populations and noxious weeds or tree diseases through the use of applied biology.

BIOLOGICAL GROWTH POTENTIAL - The average net growth attainable in a fully stocked natural forest stand. (36 CFR 2193)

BIOLOGICAL POTENTIAL - The maximum production of a selected organism that can be attained under optimum management

BIOMASS - The total quantity (at a given time) of living organisms of one or more species per unit of space (species biomass), or the total quantity of all the species in a biotic community (community biomass)

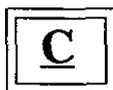

BOARD FOOT - The amount of wood equivalent to a piece of wood one foot by one foot by one inch thick

BRITISH THERMAL UNIT (BTU) - The amount of heat required to raise the temperature of one pound of water one degree Fahrenheit

BROADCAST BURN - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for a reduction of fuel hazard or as a silvicultural treatment, or both.

BRUSH - A growth of shrubs or small trees usually of a type undesirable to livestock or timber management

BUREAU OF LAND MANAGEMENT (BLM) - An agency within the Department of the Interior with land management responsibility for the Public Domain lands.

CAPABILITY - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices at a given level of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, soils and geology, as well as the application of management practices, such as silviculture or protection from fire, insects, and disease (36 CFR 219.3)

CEQ - An abbreviation of Council on Environmental Quality.

CF - An abbreviation of cubic feet.

CHARGEABLE TIMBER VOLUME - The timber removed from regulated forest land that contributes to meeting the allowable sale quantity.

CLASS I (II & III) STREAMS - See Stream Class.

CLEARCUTTING - The harvesting in one cut of all trees in an area for the purpose of creating a new, even-aged stand. The area harvested may be a patch, stand, or strip large enough to be mapped or recorded as a separate age class in planning for sustained yield.

CLIMAX - The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition.

CLIMAX SPECIES - Those species that dominate the forest stand in either numbers per unit area or biomass at climax

CODE OF FEDERAL REGULATIONS (CFR) - The listing of various regulations pertaining to management and administration of the National Forest.

COLLECTOR ROAD SYSTEM - See Roads.

COMMERCIAL FOREST LAND (CFL) - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn from timber management by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils, productivity, or watershed conditions; and (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking of young trees can be attained within 5 years after final harvest.

COMMERCIAL THINNING - Cutting by mean of sales of products (poles, posts, pulpwood, etc.) in immature forest stands to improve the quality and growth of the remaining stand.

COMMODITY - A transportable resource product with commercial value; all resource products which are articles of commerce.

COMPACTION - The packing together of soil particles by forces at the soil surface, resulting in increased soil density.

CONCERN - A point, matter, or question raised by management that must be addressed in the planning process

CONFINE - To restrict the fire spread within a predetermined area principally by use of natural or preconstructed barriers or environmental conditions. Suppression action may be minimal and limited to surveillance under appropriate conditions.

CONGRESSIONALLY CLASSIFIED AND DESIGNATED AREAS - Areas that require Congressional enactment for their establishment, such as National Wilderness Areas, National Wild, Scenic, and Recreational Rivers, and National Recreation Areas.

CONIFER - A group of cone-bearing trees, mostly evergreen, such as pine, spruce, fir, etc

CONSUMPTIVE USE - Those uses of a resource that reduce its supply

CONTAIN - To surround a fire, and any spot fires therefrom, with control line as needed, which can reasonably be expected to check the fire's spread under prevailing and predicted conditions The normal suppression tactic is indirect attack, allowing the fire to burn to human-made or natural barriers with little or no mop-up.

CONTROL - To complete the control line around a fire and around any spot fires therefrom and any interior islands of vegetation to be saved. Firefighters will also burn out any unburned area adjacent to the fire side of the control line, and cool down all hot spots that are immediate threats to the control line until the line can reasonably be expected to hold under foreseeable conditions The normal tactic is direct attack on the fire, if possible, and mop-up to extinguish all fire.

CORE AREA - (As related to spotted owl) An area encompassing at least 300 contiguous acres of old growth forest suitable for nesting and reproduction. The area consists of a portion of the territory required by a pair of owls, the nest site, and principal roost areas.

CORRIDOR - A linear strip of land identified for the present or future location of transportation or utility rights-of-way. (36 CFR 219.3)

COST EFFICIENCY - The usefulness of specified inputs (costs) to produce specified outputs (benefits) In measuring cost efficiency, some outputs, including environmental, economic, or social impacts, are not assigned monetary values but are achieved at specified levels in the least cost manner Cost efficiency is usually measured using present net value, although use of benefit-cost ratios and rates of return may be appropriate (36 CFR 219.3)

COST, CAPITAL INVESTMENT - The cost of man made structures, facilities, or improvements in natural resources used as inputs in production processes to produce outputs over one or more planning periods

COST-EFFECTIVE - Achieving specified outputs or objectives under given conditions for the least cost

COST, FIXED - A cost that is committed for the time horizon of planning or the decision being considered Fixed costs include fixed ownership requirements, fixed protection, short-term maintenance and long-term planning and inventory costs

COST, OPERATIONAL - Costs associated with administering and maintaining National Forest facilities and resource programs. This includes appropriated funds only.

COST, VARIABLE - A cost that varies with the level of controlled outputs in the time horizon covered by the planning period or decisions being considered.

COUNCIL ON ENVIRONMENTAL QUALITY (CEQ) - An advisory council to the President established by the National Environmental Policy Act of 1969. It reviews Federal programs for their effect on the environment, conducts environmental studies, and advises the President on environmental matters.

COVER/FORAGE RATIO - The mixture of cover and forage areas on a unit of land expressed as a ratio (e.g. deer summer range goal may be a 60/40 ratio).

CREATED OPENING - Created openings are openings in the Forest created by the silvicultural practices of shelterwood regeneration cutting at the final harvest, clearcutting, seed tree cutting, or group selection cutting.

CRITICAL HABITAT - For threatened or endangered species, the specific areas within the geographical area occupied by the species (at the time it is listed, in accordance with provisions of Section 4 of the Endangered Species Act) on which are found those physical or biological features essential to the conservation of the species. This habitat may require special management considerations or protecting. Protection may also be required for additional habitat areas outside the geographical area occupied by the species at the time it is listed based upon a determination of the Secretary of the Interior that such areas are essential for the conservation of the species.

CRITICAL MINERALS - Minerals essential to the national defense, but whose procurement, while difficult in case of war, is less serious than those of Strategic Minerals.

CUBIC FOOT (CF) - A unit of measure with the dimensions of one foot by one foot by one foot thick.

CULMINATION OF MEAN ANNUAL INCREMENT (CMAI) - The point where the mean annual growth of a timber stand ceases to increase prior to decline. Mean annual increment is expressed in cubic feet measure and is based upon expected growth according to the management intensities and utilization standards assumed in accordance with 36 CFR 219.16.

CULTURAL RESOURCES - Any site, structure, or object, or group of sites, structures, or objects that have been made, modified, or used by man in the past.

CUMULATIVE EFFECTS - The combined effects of two or more management activities. The effects may be related to the number of individual activities, or to the number of repeated activities on the same piece of ground. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

DECISION CRITERIA - Essentially the rules or standards used to evaluate alternatives. They are measurements or indicators that are designed to assist a decision maker in identifying a preferred choice from an array of possible alternatives.

DEFERRED ROTATION - Any grazing system which provides for a systematic rotation of the delay or discontinuance of livestock grazing on an area to provide for plant reproduction establishment or restoration of vigor.

DEMAND - The amount of output that users are willing to take at specific price, time period, and conditions of sale.

DEPARTURE - A schedule which deviates from the principle of nondeclining flow of timber harvest by exhibiting an increase in cutting levels above sustainable levels followed by a planned decrease below sustainable levels in the timber sale and harvest schedule at some time in the future.

DESIGNATED AREA (AIR QUALITY) - Those areas delineated in the Oregon and Washington Smoke Management Plans as principal population centers of air quality concern.

DESTINATION RESORT - A recreation resort designed for multi-day use in contrast to single day use

DEVELOPED RECREATION SITE - Distinctly defined area where facilities are provided for concentrated public use; e.g. campgrounds, picnic areas, boating sites, and ski areas.

DIAMETER BREAST HIGH (DBH) - The diameter of a standing tree at a point 4 feet, 6 inches from ground level.

DISCOUNT RATE - An interest rate that represents the cost or time value of money in determining the present value of future costs and benefits.

DISCOUNT RATE, REAL - A discount rate adjusted to exclude the effects of inflation.

DISCOUNTING - An adjustment, using a discount rate, for the value of money over time so that costs and benefits occurring in the future are reduced to a common time, usually the present, for comparison

DISPERSED RECREATION - Outdoor recreation that takes place outside developed recreation sites or the Wilderness

DIVERSITY - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan. (36 CFR 219.3).

DRAINAGE PATTERN - The configuration or arrangement of streams within a drainage basin or other area.

ECONOMIC EFFICIENCY - The usefulness of inputs (costs) to produce outputs (benefits) and effects when all costs and benefits that can be identified and valued are included in the computations. Economic efficiency is usually measured using present net value, though use of benefit/cost ratios and rates of return may sometimes be appropriate.

ECONOMIC IMPACT - The positive or negative change in economic conditions, including distribution and stability of employment and income in affected local, regional, and national economies, which directly or indirectly results from an activity, project or program.

ECOSYSTEM - An interacting system of organisms considered together with their environment; for example, marsh, watershed, and lake ecosystems.

EDGE - The boundary between two or more elements of the environment; e.g. field and woodland.

EDGE CONTRAST - A qualitative measure of the difference in structure of two adjacent vegetated areas; for example, low, medium, or high edge contrast.

EFFECTS - Environmental consequences as a result of a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and are later in time or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include population growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems.

The terms "Effects" and "Impacts" as used in this statement are synonymous. Effects may be ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems),

aesthetic quality, historic, cultural, economic, social, or health related, whether direct, indirect, or cumulative. Effects resulting from actions may have both beneficial and detrimental aspects, even if on balance the agency believes that the overall effects will be beneficial (40 CFR 1508.8).

ENDANGERED SPECIES - Any species of animal or plant which is in danger of extinction throughout all or a significant portion of its range. An endangered species must be designated by the Secretary of Interior as endangered in accordance with the Endangered Species Act of 1973.

ENVIRONMENTAL ANALYSIS - An analysis of alternative actions and their predictable short and long-term environmental effects, incorporating the physical, biological economic, social, and environmental design factors and their interactions.

ENVIRONMENTAL ASSESSMENT - A concise public document required by the regulations implementing the National Environmental Policy Act.

EROSION - The wearing away or detachment of the land surface by running water, wind, ice, or other geological agents, including such processes as gravitation creep.

EROSION (ACCELERATED) - Erosion much more rapid than normal, primarily as a result of the influence or the activities of man.

EROSION (NATURAL) - Wearing away of the earth's surface by water, ice, or other natural agents under natural environmental conditions of climate, vegetation, etc., undisturbed by human activity.

ESCAPED FIRE - A fire which has exceeded, or is anticipated to exceed, preplanned initial action capabilities or the fire management direction

ESCAPE COVER - Usually vegetation dense enough to hide an animal; used by animals to escape from potential enemies.

ESSENTIAL HABITAT - Areas designated by the Forest Service Regional Forester that possess the same characteristics of critical habitat as those designated by the Secretary of the Interior or Commerce

EVEN-AGED MANAGEMENT - The application of a combination of actions that results in the creation of forest stands composed of trees of essentially the same age. Managed even-aged forests are characterized by a distribution of stands of varying ages (and, therefore, tree sizes throughout the forest area) The difference in age between trees forming the main canopy level of a stand usually does not exceed 20 percent of the age of the stand at harvest rotation age. Regeneration in a particular stand is obtained in a short period at or near the time that a stand has reached the desired age or size for regeneration and is harvested. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands. (36 CFR 219.3)

EVEN-FLOW - Maintaining a relatively constant supply of timber from decade to decade

EXCLUSION AREA - An area having a statutory prohibition to rights-of-way for linear facilities or corridor designation

EXPECTED BURNED ACREAGE - The expected annual number of acres burned by fire size class and intensity level for a given program option or budget level.

EXTENDED SHELTERWOOD - This is a variation of the shelterwood system design to provide for other resources such as wildlife or scenery considerations. The term extended is used to denote the retention of the old stand for a longer period than is necessary or, in many cases, desirable for maximum growth of the new stand.

EXTIRPATION - Extermination.

FINAL REMOVAL - The removal of the last seed bearers or shelter trees after regeneration is established under a shelterwood system

FIRE MANAGEMENT ANALYSIS ZONE - The geographically delineated areas into which the planning unit is divided for the purpose of fire management analysis. The delineation is based upon common fire-behavior characteristics which is the "corner stone" for fire planning and evaluation of fire effects.

FIRE MANAGEMENT DIRECTION - The direction provided by an interdisciplinary team for each separate management area on the Forest. It includes guides by management area for long-term maximum burn acreages, specifying fire size and intensity, which would not adversely affect attainment of resource targets or outputs. In addition, it provides guidelines on desired residue profiles and the use of fire to meet resource prescriptions.

FIRE PROGRAM OPTION - A given program mix funded at a given program level. Options are developed in response to specific fire management direction established for the Forest Plan. The objective is to identify the most cost-efficient option meeting resource protection and management objectives.

FLOOD PLAINS - Lowland and relatively flat areas adjoining inland and coastal water including, as a minimum, that area subject to one percent or greater chance of flooding in any given year.

FORAGE - All browse and non woody plants available to livestock or wildlife for grazing or harvestable for feed.

FORB - Any herb other than grass.

FORDRY - That forested ecotype where the climax conifer species is Douglas-fir or ponderosa pine.

FOREGROUND - A term used in visual (scenery) management to describe the stand of trees immediately adjacent to a high-value scenic area, recreation facility, or forest highway (see "Background", "Middleground")

FOREST LAND - Land at least 10 percent occupied by forest trees of any size or formerly having had such cover and not currently developed for non-forest use. Lands developed for non-forest use include areas devoted to crops, improved pasture, residential or administrative areas, improved roads of any width and adjoining road clearing and powerline clearing of any width. (36 CFR 219.3)

FOREST AND RANGELAND RENEWABLE RESOURCES PLANNING ACT (RPA) 1974 - An act of Congress requiring the preparation of a program for the management of the National Forest's renewable resources and preparation of land and resource management plans for units of the National Forest System. It also requires a continuing inventory of all National Forest System lands and renewable resources.

FOREST-WIDE STANDARD - A principle requiring a specific level of attainment; a rule to measure against. The Forest-wide Standards apply to all areas of the Forest regardless of the other prescriptions applied.

FORPLAN - A linear programming system used for developing and analyzing Forest Planning Alternatives.

FORWET - That forested ecotype where conifer trees other than Douglas-fir or ponderosa pine are climax species over time. Characterized by more available moisture than the forested dry (FORDRY) zone.

FREE-TO-GROW - A term used by silviculturists to indicate that trees are free of growth restraints, the most common of which is competing overtopping vegetation.

FUELBREAK - Any natural or constructed barrier utilized to segregate, stop, or control the spread of fire.

FUELS - Any material that will carry and sustain a forest fire, primarily natural materials, both live and dead.

FUEL TREATMENT - The rearrangement or disposal of natural or activity fuels to reduce the fire hazard.

G

GAME - Wildlife that are hunted for sport and regulated by State Game regulations

GENERAL DISTRIBUTION - The geographic area presently occupied, often on a seasonal basis, by a species within the planning area. Distribution is not to be confused with present occupancy of specific habitat(s). Resource management activities will create changes in habitat which will force local shifts in occupancy.

GENERAL FOREST (GF) - The portion of the Forest where timber management and other consumptive uses are emphasized

GENETIC INTEGRITY - Refers to a normal healthy genetic pool (foundation) within a biological population to provide for long-term maintenance and survival of the species. Of specific concern in management direction is the prevention of loss of genetic variance (heterozygosity) and the avoidance of inbreeding depression, an important part of a given population's genetic integrity within the gene pool.

GOAL - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad general terms and is timeless in that it has no specific date by which it is to be completed. Goal statements form the principle basis from which objectives are developed. (36 CFR 219.3)

GOODS AND SERVICES - The various outputs, including on-site uses, produced from forest and rangeland resources (36 CFR 219.3)

GRADIENT - Change of elevation, velocity, pressure or other characteristics per unit length of slope

GROUP SELECTION CUTTING - Removal of tree groups ranging in size from a fraction of an acre up to about 2 acres in area that is smaller than the minimum feasible for even-aged management of a single stand.

GUIDELINE - An indication or outline of policy or conduct; i.e. any issuance that assists in determining the course of direction to be taken in any planned action to accomplish a specific objective.

GULLY - A channel or miniature valley cut by concentrated runoff but through which water commonly flows only during and immediately after heavy rains or during the melting of snow

GULLY EROSION - The erosion process whereby water accumulates in narrow channels and, over short periods, removes the soil from this narrow area to considerable depths, ranging from one to two feet to as much as 75 to 100 feet.

H

HABITAT - The place where a plant or animal naturally or normally lives and grows.

HABITAT CAPABILITY - The estimated ability of an area, given existing or predicted habitat conditions, to support a wildlife, fish or plant population. It is measured in terms of potential population numbers.

HARVEST CUTTING METHOD - A combination of interrelated actions whereby forests are tended, harvested, and replaced. The combination of management practices used to manipulate the vegetation in forests. Harvest cutting methods are classified as even-aged and uneven-aged.

HEAVING - The partial lifting of plants out of the ground, frequently breaking their roots, as a result of freezing and thawing of the surface soil during the winter.

HIDING COVER - Vegetation capable of hiding 90 percent of a standing deer or elk from the view of a human at a distance of 200 feet.

HIGH QUALITY HABITAT - Habitat which completely satisfies a species existence requirement.

HORIZONTAL DIVERSITY - The distribution and abundance of plant and animal communities or successional stages across an area of land; the greater the number of communities, the higher the degree of horizontal diversity. This concept is close to, but not exactly the same as, "even-aged management," although each may influence the other. Application of even-aged management, for example, can be designed to accomplish horizontal diversity objectives.

HUMAN RESOURCE PROGRAMS - Providing human and natural resource benefits through administering and hosting programs in work, training, and education for the unemployed, the underemployed, the elderly, the young and others with special needs.

HYDRAULIC GRADIENT - The slope of the hydraulic grade line. The slope of the free surface of water flowing in an open channel.

INDICATOR SPECIES - A wildlife management scheme in which the welfare of a selected species is presumed to indicate the welfare of other species. The condition of the selected species can be used to assess the impacts of management actions on a particular area.

INITIAL ACTION - The prompt, preplanned response to a wildfire.

INTEGRATED PEST MANAGEMENT - A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are studied and weighed. The information considered in selecting appropriate strategies includes the impact of the unregulated pest population on various resources values, alternative regulatory tactics and strategies, and benefit/cost estimates for these alternative strategies. Regulatory strategies are based on sound silvicultural practices and ecology of the pest-host system and consist of a combination of tactics such as timber stand improvement plus selective use of pesticides. A basic principle in the choice of strategy is that it be ecologically compatible or acceptable. (36 CFR 219.3)

INTEGRATED RESOURCE MANAGEMENT - A management strategy which emphasizes no resource element to the exclusion or violation of the minimum legal standards of others.

INTENSIVE FOREST MANAGEMENT - A high investment level of timber management that includes regeneration with genetically improved seedling stock, control of competing vegetation, fill-in planting, precommercial thinning as needed for stocking control, and one or more commercial thinnings.

INTERDISCIPLINARY TEAM (ID TEAM) - A team of people that collectively represent several disciplines and whose duty it is to coordinate and integrate the planning activities.

INTERMITTENT STREAM - A stream that runs water in most months, but does not run water during dry seasons of most years.

INVENTORIED ROADLESS AREA - Areas of undeveloped Federal land, greater than 5,000 acres in size, within which there are no improved roads maintained for travel by means of motorized vehicles intended for highway use. Exceptions are those areas less than 5,000 acres manageable in their natural condition, contiguous to existing wilderness, or are of issue to the public.

IRRETRIEVABLE - Applies to losses of production, harvest, or use of renewable natural resources. For example, some or all of the timber production from an area is irretrievably lost during the time an area is used as a winter sports site. If the use is changed, timber production can be resumed. The production lost is irretrievable, but the action is not irreversible.

IRREVERSIBLE - Applies primarily to the use of nonrenewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long time periods. Irreversible also includes loss of future options.

ISSUE - A point, matter, or question of public discussion or interest to be addressed or decided through the planning process.

K

KNUTSON-VANDENBERG ACT (KV) - Legislation authorizing the collection of money from timber sale receipts for reforestation, stand improvements, and other resource improvement or mitigation projects on timber sale areas

KV - An abbreviation of Knutson-Vandenberg.

L

LAND ALLOCATION - The assignment of a management emphasis to particular land areas with the purpose of achieving the goals and objectives of that alternative.

LANDINGS - Those designated areas within a timber sale where logs are temporarily stored before transport to a mill.

LANDTYPE - A portion of the landscape resulting from geomorphic and climatic processes with defined characteristics having predictable soil, hydrologic, engineering productivity, and other behavior.

LEASABLE MINERALS - Coal, oil, gas, phosphate, sodium, potassium, oil shale, sulphur, geothermal steam
Also includes other minerals on acquired National Forest lands

LIMITING HABITAT - Habitat which restricts the distribution, numbers, or condition of an organism.

LOCATABLE MINERALS - Generally includes those hardrock minerals which are mined and processed for the recovery of metals, but may also include certain non-metallic minerals and uncommon varieties of mineral materials.

LONG-TERM SUSTAINED YIELD TIMBER CAPACITY - The highest uniform wood yield from lands being managed for timber production that may be sustained under a specified management intensity consistent with multiple-use objectives. (36 CFR 219.3)

M

M - Thousand

MANAGEMENT AREA - An area with similar management objectives and a common management prescription

MANAGEMENT CONCERN - An issue, problem, or a condition which constrains the range of management practices identified by the Forest Service in the planning process. (36 CFR 219.3)

MANAGEMENT DIRECTION - A statement of multiple-use and other goals and objectives, the associated management prescriptions, and standards and guidelines for attaining them (36 CFR 219.3)

MANAGEMENT INTENSITY - The management practice or combination of management practices and associated costs designed to obtain different levels of goods and services (36 CFR 219.3)

MANAGEMENT PRACTICE - A specific activity, measure, course of action, or treatment. (36 CFR 219.3)

MANAGEMENT PRESCRIPTION - Management practices and intensity of management selected and scheduled for application on a specific area to attain multiple-use and other goals and objectives. (36 CFR 219.3)

MANAGEMENT REQUIREMENT (MR) - Minimum standards for resource protection, vegetation manipulation, silvicultural practices, even-aged management, riparian areas, and soil and water resources, to be met in accomplishing National Forest System goals and objectives.

MARGINAL TIMBER COMPONENT - Timber on which the income just equals or could just equal the costs of production under a given form of management

MARKET RESOURCES - Products derived from renewable and nonrenewable resources that have a well-established market value; for example, forage, timber, water, and minerals.

MARKET VALUE - The unit price of an output normally exchanged in a market after at least one stage of production, expressed in terms of what people are willing to pay.

MASS MOVEMENT - A general term for any of the variety of processes by which large masses of earth material are moved down slope by gravitational forces, either slowly or quickly

MATURE TIMBER - Trees that have attained full development, particularly in height, and are in full seed production.

MAXIMUM MODIFICATION - A visual quality objective meaning man's activity may dominate the characteristic landscape but should appear as a natural occurrence when viewed as background

MBF - Thousand board feet. A measure of wood volume.

MCF - Thousand cubic feet. A measure of wood volume. The conversion ratio for the Wenatchee National Forest is 5.45 board feet per one cubic foot of wood.

MEAN ANNUAL INCREMENT OF GROWTH - The total increase in girth, diameter, basal area, height, or volume of individual trees or a stand up to a given age, divided by that age.

MIDDLEGROUND - A term used in visual management to describe the visible terrain beyond the foreground where individual trees are still visible but do not stand out distinctly from the stand

MINERAL SOIL - Weathered rock materials usually containing less than 20 percent organic matter.

MINERAL WITHDRAWAL - The exclusion of locatable mineral deposits from mineral entry on areas required for administrative sites by the Forest Service and other areas highly valued by the public. Public lands withdrawn from entry under the General Mining Laws and/or the Mineral Leasing Laws

MINIMUM VIABLE POPULATION - The low end of the viable population range

MINING CLAIMS - That portion of the public estate held by law for mining purposes in which the right of exclusive possession of locatable mineral deposits is vested to the locator of a deposit

MITIGATION - Actions to avoid, minimize, reduce, eliminate, or rectify the impact of a management practice

MM - Million.

MMBF - Million board feet

MMCF - Million cubic feet.

MONITORING - The periodic evaluation of Forest Plan management practices on a sample basis to determine how well objectives have been met.

MODIFICATION - A visual quality objective meaning man's activity may dominate the characteristic landscape but must, at the same time, utilize natural established form, line, color, and texture. It should appear as a natural occurrence when viewed in foreground or middleground.

MULTIPLE USE - The management of all the various renewable surface resources of the National Forests so that they are utilized in the combination that will best meet the needs of the American people. The concept also includes making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in the use to conform to changing needs and conditions. Some lands will be used for less than all of the resources. There will be harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land. Consideration will be given to the relative values of the various resources, and management will not necessarily favor the combination of uses that will give the greatest dollar return or the greatest unit output.

MUNICIPAL SUPPLY WATERSHED - A watershed that provides water for human consumption where Forest Service management could have a significant effect upon the quality of water at the point of intake. The watershed must provide water utilized by a community or any other public water system regularly serving 25 individuals at least 60 days out of the year or provide at least 15 service connections. This definition can include such facilities as campgrounds, organization camps, resorts, residential areas, etc.

NAAQS - National Ambient Air Quality Standards

NATIONAL ENVIRONMENTAL POLICY ACT OF 1969 (NEPA) - An Act, to declare a National policy which will encourage productive and enjoyable harmony between man and his environment, to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man, to enrich the understanding of the ecological systems and natural resources important to the nation, and to establish a Council on Environmental Quality.

NATIONAL FOREST MANAGEMENT ACT OF 1976 (NFMA) - An Act amending the Forest and Rangeland Renewable Resources Planning Act. NFMA requires the preparation of Regional and Forest Plans and the preparation of regulations to guide that development

NATIONAL FOREST SYSTEMS - All National Forest lands reserved or withdrawn from the public domain of the United States, all National Forest lands acquired through purchase, exchange, donation, or other means, the National Grasslands and land utilization projects administered under Title III of the Bankhead-Jones Farm Tenant Act (50 Stat. 525, 7 U.S.C. 1010-1012), and other lands, waters or interests therein which are administered by the Forest Service or are designated for administration through the Forest Service as a part of the system. (16 U.S.C. 1608)

NATURAL FOREST - The condition of a forest environment at any point in time including its associated plant and animal communities, which has been reached essentially through the process of natural succession. This process would include the effects of natural catastrophic occurrences.

NDF - An abbreviation of Non-Declining Flow

NEPA - An abbreviation of National Environmental Policy Act.

NET PUBLIC BENEFITS - An expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index. The maximization of net public benefits to be derived from management of the units of the National Forest System is consistent with the principles of multiple-use and sustained-yield (36 CFR 219.3)

NET VALUE CHANGE - The estimation process carried out by an interdisciplinary team to assess positive and negative effects of individual resource allocation or management area designation. An estimation of physical effects and economic consequences of various fire intensity levels.

NFMA - An abbreviation of the National Forest Management Act of 1976.

NON-CHARGEABLE TIMBER HARVEST - Timber harvest that is not chargeable to the allowable sale quantity.

NON-CONSUMPTIVE USE - That use of a resource that does not reduce the supply.

NON-DECLINING FLOW (NDF) - A level of timber production assigned so that the planned timber sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade.

NON-GAME - Any species of wildlife or fish which is not managed or otherwise controlled by hunting, fishing, or trapping regulations.

NON-MARKET - Products derived from National Forest resources that do not have a well-established market value, for example, recreation, wilderness, wildlife

NON-POINT SOURCE POLLUTION - Pollution whose source is general rather than specific in location

NON-PRICED OUTPUTS - Outputs for which there is no available market transaction evidence and no reasonable basis for estimating a dollar value. Subjective non-dollar values are given to non-priced outputs

NOXIOUS WEEDS - A plant considered to be extremely destructive or harmful to agriculture and designated by law. An undesirable species that conflicts with, restricts, or otherwise causes problems with the management objectives.

NPB - An abbreviation of net public benefits.

OBJECTIVE - A concise, time-specific statement of measurable planned results that respond to pre-established goals. An objective forms the basis for further planning to define the precise steps to be taken and the resources to be used in achieving identified goals. (36 CFR 219.3)

OCCUPANCY TRESPASS - The illegal occupation or possession of National Forest land or property

OFF-ROAD VEHICLE (ORV) - Any motorized vehicle designed for or capable of cross-country travel on or immediately over land, water, snow, ice, or other natural terrain

OLD GROWTH STAND - An old-growth stand is defined as any stand of trees 10 acres or greater generally containing the following characteristics: 1) stands contain mature and overmature trees in the overstory and are well into the mature growth stage; 2) stands will usually contain a multilayered canopy and trees of several age classes; 3) standing dead trees and down material are present, and 4) evidence of man's activities may be present but does not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand.

OLIGOTROPHIC - Lakes having low nutrient supplies which are poor producers of organic matter.

OPPORTUNITY COSTS - The values of a resource's foregone net benefits in its most economically efficient alternative use.

OPTIMUM DENSITY - For wildlife, the maximum rate of animal stocking possible without inducing damage to vegetation or related resources, may vary from year to year because of environmental and/or population factors

ORV - An abbreviation for off-road vehicles.

OUTPUT - A good, service, or on-site use that is produced from forest and rangeland resources. See FSH 1309.11 for forest and rangeland outputs, codes and units of measure Examples: X06 - Softwood Sawtimber production - MCF; X80 - Increased Water Yield - Acre feet; W01 - Primitive Recreation Use - RVD's

OVERSTORY - That portion of the trees in a forest of more than one story, forming the upper or uppermost canopy layer.

PAOT - Persons At One Time - Public recreational measurement term. The number of people in an area or using a facility at one time.

PARENT MATERIAL - The unconsolidated and more or less chemically weathered mineral or organic matter from which the upper horizons of the soil profile are developed.

PARTIAL CUT - Covers a variety of silvicultural practices where a portion of the stand is removed and a portion is left.

PARTIAL RETENTION - A visual quality objective where man's activities may be evident but subordinate to the characteristic landscape.

PARTICULATES - Small particles suspended in the air and generally considered pollutants.

PATENTED MINING CLAIMS - A patent is a document which conveys a title Public law provides that when patented, a mining claim becomes private property and is land over which the United States has no property rights, except as may be reserved in the patent After a mining claim is patented, the owner does not have to comply with requirements of the General Federal Mining law, but is required to meet State regulations.

PAYMENT IN LIEU OF TAXES - Payments to local or State governments based on ownership of Federal land and not directly dependent on production of outputs or receipt sharing Specifically, they include payments made under the Payments in Lieu of Taxes Act of 1976 by U.S. Department of the Interior.

PERENNIAL STREAMS - A stream that runs water year around.

PERSONS-AT-ONE-TIME (PAOT) - A recreation capacity measurement term indicating the number of people that can use a facility or area at one time.

PLANNING AREA - The area of the National Forest System covered by a regional guide or Forest Plan (36 CFR 219.3)

PLANNING HORIZON - The overall time period considered in the planning process that spans all activities covered in the analysis or plan and all future conditions and effects of proposed actions which would influence the planning decisions (36 CFR 219.3)

PLANNING PERIOD - One decade The time interval within the planning horizon that is used to show incremental changes in yields, costs, effects, and benefits. (36 CFR 219.3)

PLANT COMMUNITIES - A vegetation complex unique in its combination of plants which occur in particular locations under particular influences. A plant community is a reflection of integrated environmental influences on the site - such as soils, temperature, elevation, solar radiation, slope, aspect, and rainfall

PNV - An abbreviation of present net value

POTENTIAL YIELD - (This term is in reference to the Timber Management plans only.) Optimum sustained yield of timber harvest volume attainable with intensive forestry on available commercial forest land (forest lands able to produce 20 cubic feet of timber per acre per year or more) while considering the interrelationship with other forest resources and uses. Programmable net salvage volume and volume from marginally economical lands are also included.

PRACTICES - Those management activities that are proposed or expected to occur.

PRECOMMERCIAL THINNING - The selective felling or removal of trees in a young stand, primarily to accelerate diameter increment on the remaining stems, maintain a specific stocking or stand density range, and improve the vigor and quality of the trees that remain

PRESCRIBED FIRE - A wildland fire burning under preplanned specified conditions which will accomplish certain planned objectives. The fire may result from either planned or unplanned ignitions

PRESCRIBED NATURAL FIRE - The use of unplanned natural ignitions to meet management prescriptions

PRESENT NET VALUE (PNV) - The difference between the discounted values (benefits) of all outputs to which monetary values or established market prices are assigned, and the total discounted costs of managing the planning area. (36 CFR 219.3)

PRESERVATION - A visual quality objective that allows only ecological changes to take place

PRESUPPRESSION - Activities required in advance of fire occurrence to ensure an effective suppression action. It includes (1) recruiting and training fire forces, (2) planning and organizing attack methods, (3) procuring and maintaining fire equipment, and (4) maintaining structural improvements necessary for the fire program.

PRICE - The unit value of an output expressed in dollars.

PRIMARY CAVITY EXCAVATOR - Wildlife species that digs or chips out cavities in wood to provide itself or its mate with a site for nesting or roosting.

PRIMITIVE RECREATION - Those recreation activities which occur in areas characterized by an essentially unmodified natural environment of fairly large size (2,500 acres or greater).

PRODUCTION POTENTIAL - The capability of the land or water to produce a given resource.

PRODUCTIVE FOREST LANDS - Forest lands that are capable of producing crops of industrial wood and have not been reserved or deferred from timber management

PROGRAM DEVELOPMENT AND BUDGETING - The process by which forest management activities are proposed and funded.

PROGRAM ELEMENT - An individual Forest Service area of responsibility, which in combination with other elements, comprises the statutory or Executive directed mission of the Forest Service. Specific Forest Service program elements are defined in the Management Information Handbook (FSH 1309.11)

PROGRAMMED HARVEST - The amount of timber that is scheduled for harvesting. Includes salvage and cull timber volumes. It is based on current demand, funding, and multiple use considerations.

PUBLIC ACCESS - Usually refers to a road or trail route over which a public agency claims a right-of-way for public use.

PUBLIC ISSUE - A subject or question of widespread public interest relating to management of the National Forest System. (36 CFR 219.3)

PURCHASER CREDIT - Credit earned by the purchaser of a National Forest timber sale in return for construction of contract-specified roads. Earned purchaser credit may be used by the purchaser as payment for National Forest timber removed

RANGE ALLOTMENT - A designated area containing land suitable and available for livestock grazing use upon which a specified number and kind of livestock are grazed under an approved allotment management plan. It is the basic management unit of the range resource on National Forest System lands administered by the Forest Service.

RANGER DISTRICT - An administrative subdivision of the Forest, supervised by a District Ranger who reports to the Forest Supervisor.

RAPTORS - Any predatory bird - such as a falcon, hawk, eagle or owl - that has feet with sharp talons or claws adapted for seizing prey and a hooked beak for tearing flesh.

RARE II - An abbreviation of Roadless Area Review and Evaluation II.

REAL DOLLAR VALUE - A monetary value that compensates for the effects of inflation. (36 CFR 219.3)

RECORD OF DECISION (ROD) - A document separate from but associated with an Environmental Impact Statement which states the decision, identifies all alternatives, specifying which were environmentally preferable, and states whether all practicable means to avoid environmental harm from the alternative have been adopted, and if not, why not. (40 CFR 1505.2)

RECREATION CAPACITY - The number of people that can take advantage of recreation opportunity at any one time without substantially diminishing the quality of the experience or the biophysical resources.

RECREATION INFORMATION MANAGEMENT (RIM) - The Forest Service system for recording recreation facility condition and use.

RECREATION OPPORTUNITY - An opportunity for a user to participate in a preferred activity within a preferred setting, in order to realize those satisfying experiences which are desired

RECREATION OPPORTUNITY SPECTRUM (ROS) - Land delineations that identify a variety of recreation experience opportunities categorized into six classes on a continuum from primitive to urban. Each class is defined in terms of the degree to which it satisfies certain recreation experience needs. This is measured based on the extent to which the natural environment has been modified, the type of facilities provided, the degree of outdoor skills needed to enjoy the area, and the relative density of recreation use. The seven classes are

1. **Primitive**--Area is characterized by an essentially unmodified natural environment of fairly large size. Interaction between users is very low, and evidence of other users is minimal. The area is managed to be essentially free from evidence of management restrictions and controls. Motorized use within the area is not permitted.

2. **Semi-primitive Non-motorized**--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Interaction between users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but subtle. Motorized recreation use is not permitted, but local roads used for other resource management activities may be present on a limited basis. Use of such roads is restricted to minimize impacts on recreational experience opportunities.

3. Semi-primitive Motorized--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but subtle. Motorized recreation use of local primitive or collector roads with predominantly natural surfaces and trails suitable for motor bikes is permitted.

4. Roaded Natural--Area is characterized by predominantly natural-appearing environments with moderate evidence of the sights and sounds of man. Such evidence usually harmonizes with the natural environment. Interaction between users may be moderate to high, and evidence of other users prevalent. Resource modification and utilization practices are evident but harmonize with the natural environment. Conventional motorized use is allowed and incorporated into construction standards and design of facilities

5. Roaded Modified--Area is generally natural appearing, but has significant vegetation management and resource modification. Modifications generally harmonize with the natural environment. A moderate opportunity exists for isolation and undisturbed activities but some interaction with other visitors can be expected. Conventional motorized use is allowed and incorporated into construction standards and designs of facilities

6. Rural--Area is characterized by a natural environment that has been substantially modified by development of structures, vegetative manipulation, or pastoral agricultural development. Resource modification and utilization practices may be used to enhance specific recreation activities and to maintain vegetative cover and soil. Sights and sounds of humans are readily evident, and the interaction between users is often moderate to high. A considerable number of facilities are designed for use by a large number of people. Facilities are often provided for special activities. Moderate user densities are present away from developed sites. Facilities for intensified motorized use and parking are available.

7. Urban--Area is characterized by a substantially urbanized environment, although the background may have natural-appearing elements. Renewable resource modification and utilization practices are often used to enhance specific recreation activities. Vegetative cover is often exotic and manicured. Sights and sounds of humans are predominant on site and in nearby areas. Facilities for highly intensified motor use and parking are available with forms of mass transit often available to carry people throughout the site.

RECREATION VISITOR DAY (RVD) - A unit for measuring recreation use, with 12 visitor hours in a visitor day. This may consist of one person for 12 hours, 12 persons for one hour, or any equivalent combination of continuous or intermittent recreation use by individuals or groups

REFORESTATION - The natural or artificial restocking of an area with forest trees; most commonly used in reference to artificial restocking.

REGENERATION - The actual seedlings and saplings existing in a stand, or the act of establishing young trees naturally or artificially.

REGENERATION CUT - Any removal of trees to make regeneration possible.

REGION - An area covered by a Regional guide. See FSM 1221.3 for organizational definitions.

REGIONAL FORESTER - The official responsible for administering a single Forest Service region.

REGIONAL GUIDE - The guide developed to meet the requirements of the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended. It guides all natural resource management activities, and establishes management standards and guidelines for the National Forest System lands within a given region, it also disaggregates the assigned Regional RPA objectives to the Forests within that Region

REGULATED VOLUME - Same as Allowable Sale Quantity

REHABILITATION - A short-term management alternative used to return existing visual impacts in the natural landscape to a desired visual quality

RELEASE - Freeing a tree or group of trees from competition by cutting or otherwise eliminating vegetation that is overtopping or closely surrounding them.

REMOVAL CUT (Final Cut) - The removal of the last seed bearing or shelter trees after regeneration is established under a shelterwood method.

RESEARCH NATURAL AREA - An area of land in as near a natural condition as possible that exemplifies typical or unique vegetation and associated biotic, soil, geologic, and aquatic features. The area is set aside to preserve a representative sample of an ecological community primarily for non-manipulative scientific and education purposes.

RESERVED FOREST LAND - Public forest land withdrawn from timber utilization through statute or administrative regulations (e.g. Wilderness, Research Natural Areas).

RESIDENT FISH - Generally refers to trout and char which are not anadromous. However, some Forest reservoirs contain warmwater resident fish species such as bass.

RESIDUAL STAND - The trees remaining standing after some form of selection cutting is performed on a stand.

RESIDUE - Material which includes both desired and unwanted vegetative residues which result from an activity or natural event

RESOURCE PLANNING ACT (RPA) - The Forest and Rangeland Renewable Resources Planning Act of 1974 Also refers to the National Assessment and Recommended Program developed to fulfill the requirements of the Act

RESPONSIBLE LINE OFFICER - For land management planning purposes, the Forest Service employee who has been delegated the authority to carry out a specific planning action (36 CFR 219.3)

REST-ROTATION - A system of grazing management which defines systematically recurring periods of grazing and deferment for two or more pastures or management units.

RETENTION - A visual quality objective where human activities are not evident to the casual forest visitor.

RILL EROSION - An erosion process in which numerous small channels only several inches deep are formed, occurs mainly on recently cultivated or disturbed soils.

RIPARIAN - Pertaining to acres of land directly influenced by water. Riparian areas usually have visible vegetative or physical characteristics reflecting this water influence Stream sides, lake borders, or marshes are typical riparian areas.

RIPARIAN-AQUATIC PROTECTION ZONE - A geographically delineated area with distinctive resource values and characteristics that is comprised of aquatic and riparian ecosystems. This includes floodplains, wetlands, and all areas within a variable horizontal distance from the normal line of high water of a stream channel or from the shoreline of a standing body of water

RISK - The degree and probability of loss based on chance

RUNOFF - That part of the water which travels over the soil surface to the nearest outlet or channel

RNA - An abbreviation of Research Natural Area.

ROAD - A general term denoting a way for purposes of travel by vehicles greater than 40 inches in width

a. **Forest Arterial Road**. Provides services to large land areas and usually connects with public highways or other Forest arterial roads to form an integrated network of primary travel routes. The location and standard are often determined by a demand for maximum mobility and travel efficiency rather than specific resource management service. It is usually developed and operated for long-term land and resource management purposes and constant service (FSM 7710.51).

b. **Forest Collector Road**. Serves smaller land areas than a Forest arterial road and is usually connected to a Forest arterial or public highway. Collects traffic from Forest local roads and/or terminal facilities. The location and standard are influenced by both long-term multiresource service needs as well as travel efficiency. May be operated for either constant or intermittent service, depending on land use and resource management objectives for the area served by the facility (FSM 7710.51).

c. **Forest Local Road**. Connects terminal facilities with Forest collector or Forest arterial roads or public highways. The location and standard are usually controlled by specific resource activity requirements rather than travel efficiency needs (FSM 7710.51).

ROADLESS AREA - See Inventoried Roadless Area.

ROADLESS AREA REVIEW AND EVALUATION II (RARE II) - The national inventory of roadless and undeveloped areas within the National Forest and grasslands. This refers to the second such assessment, which was documented in the Final Environmental Impact Statement of the Roadless Area Review and Evaluation, January 1979.

ROS - An abbreviation of Recreation Opportunity Spectrum.

ROTATION - Planned number of years, between the formation of a generation of trees and its final harvest of a specified stage of maturity.

ROTATION AGE - The age of a stand when harvested.

ROUNDWOOD - Commercially valuable wood that is generally too small to be made into boards.

RPA - The Forest and Rangeland Renewable Resources Planning Act of 1974. Also refers to the National Assessment and Recommended Program developed to fill the requirements of the Act.

RPA RESOURCE TARGETS - Quantified resource goals stated in the Forest Service Region 6 plan

RVD's An abbreviation of Recreation Visitor Days

SALE SCHEDULE - The quantity of timber planned for sale by time period from an area of suitable land covered by a forest plan. The first period (usually a decade) of the selected sale schedule provides the allowable sale quantity. Future periods are shown to ensure that long term sustained yield will be achieved and maintained (36 CFR 219.3)

SALVAGE CUTTING - Intermediate cuttings made to remove trees that are dead or in imminent danger of being killed by injurious agents

SANITATION CUTTING - The removal of dead, damaged or susceptible trees primarily to prevent the spread of insect pests or diseases.

SATURATION DENSITY - (Same as tolerance density.) This term relates to the requirement of many wildlife species for living space. This condition is most marked in territorial species. Space is the limiting factor to the further increases of the population density of these species

SCENIC AREAS - Places of outstanding or matchless beauty which require special management to preserve these qualities. They may be established under 36 CFR 294.1 whenever lands possessing outstanding or unique natural beauty warrant this classification.

SCENIC RIVERS - See Wild and Scenic Rivers.

SCHEDULED TIMBER HARVEST - Timber harvest that is chargeable to the annual allowable sale quantity for the Forest.

SCOPING PROCESS - A part of the National Environmental Policy Act (NEPA) process; early and open activities used to determine the scope and significance of the issues; and the range of actions, alternatives, and impacts to be considered in an Environmental Impact Statement (40 CFR 1501.7).

SCORP - Statewide Comprehensive Outdoor Recreation Plan.

SECOND GROWTH - Forest growth that has become established following some interference with the previous forest growth (e.g , cutting, serious fire, or insect attack)

SECONDARY USER SPECIES - Wildlife that occupies a site (cavity in a snag or a den) created by another species.

SEDIMENT - Solid material, both mineral and organic, that is in suspension, and is being transported from its site of origin by air, water, gravity, or ice, or has come to rest on the earth's surface either above or below sea level.

SEDIMENT YIELD - the total sediment outflow from a drainage basin in a specified period of time.

SEED TREE CUTTING - Removing all mature trees from a stand except for selected seed-bearing trees retained on site to provide a seed source for stand regeneration.

SELECTION CUT - Selection cutting is the periodic removal of mature trees individually or in small groups from an uneven-aged forest. By this method, both regeneration cutting and tending of immature stand components are accomplished at each entry.

SEMI-PRIMITIVE MOTORIZED ROS CLASS - See RECREATION OPPORTUNITY SPECTRUM

SEMI-PRIMITIVE NON-MOTORIZED ROS CLASS - See RECREATION OPPORTUNITY SPECTRUM.

SENSITIVE SPECIES - Those species of plants or animals that have appeared in the Federal Register as proposed for classification and are under consideration for official listing as endangered or threatened species, that are on an official State list, or that are recognized by the Regional Forester as needing special management to prevent their being placed on Federal or State lists.

SERAL - A biotic community which is a developmental, transitory stage in an ecological succession

SERAL STAGE--See "successional stage"

SHELTERWOOD CUTTING - Any regeneration cutting in a stand designed to establish a new stand under the protection (overhead or side) of the old stand. Usually the shelterwood involves two separate harvest operations. The first harvest (seed cut) is designed to create space and seed production to establish new trees. The second cut (removal cut) is designed to remove the remainder of the old stand before it begins to compete with the new stand for light and nutrients. This is usually within 10 years (See also EXTENDED SHELTERWOOD.).

SHEET EROSION - The removal of a fairly uniform layer of soil from the land surface by runoff water.

SILVICULTURAL SYSTEM - A management process whereby forests are tended, harvested, and replaced resulting in a forest of distinctive form. Systems are classified according to the logging method that removes the mature crop and provides for regeneration and according to the type of forest thereby produced. (36 CFR 219.3)

SILVICULTURE - The art and science of controlling the establishment, composition and growth of forests.

SITE INDEX - A numerical evaluation of the quality of land for plant productivity which uses height growth as a function of age.

SITE PRODUCTIVITY - Production capability of specific areas of land to produce defined outputs such as AUMs, cubic feet/acre/yr., etc.

SIZE CLASS - For purposes of Forest planning, size class refers to the three intervals of tree stem diameter used for classification of timber in the Forest Plan data base:

less than five-inch diameter = seedling/sapling
five to eight-inch diameter = pole timber
greater than eight-inch diameter = sawtimber

SLASH - The wood residue left on the ground after timber cutting and/or accumulating there as a result of storm, fire, or other damage. It includes unused logs, uprooted stumps, broken or uprooted stems, branches, twigs, leaves, bark, and chips.

SMALL GAME - Birds and small mammals typically hunted or trapped.

SMOLT HABITAT CAPABILITY - Smolt habitat capability is a measure of the productive capability of aquatic habitat to produce smolts of a given species

SNAG - A standing dead tree.

SOCIOECONOMIC - Pertaining to, or signifying the combination or interaction of, social and economic factors

SOHA - An abbreviation for Spotted Owl Habitat Area

SOIL - The unconsolidated mineral and organic material on the immediate surface of the earth.

SOIL and WATER CONSERVATION PRACTICES (SWCP) -- The set of practices which ensures that soil productivity is maintained, soil loss and water quality impacts are minimized, and water related beneficial are protected during implementation of a project. These practices include the following: (1) State recognized Best Management Practices, (2) Forest-wide standards and guidelines (3) Management Area standards and guidelines, and (4) practices identified at the area and project levels based on on-site specific evaluation.

SOIL DISTURBANCE - Soil disturbance is the mixing of duff material or other woody material into the surface horizon or horizons without significant movement of the soil from one spot to another.

SOIL RESOURCE COMMITMENT - Soil resource commitment is a conversion of a productive site to an essentially nonproductive site for a period of more than 50 years.

SOIL SURVEYS - Systematic examinations of soils in the field and in laboratories which are then interpreted according to their adaptability for various crops, grasses and trees.

SOUND WOOD - Timber that is free from defect, damage, or decay; i.e., in solid, whole, good condition

SPECIAL TIMBER COMPONENT - (obsolete term) That part of the planned timber harvest area and volume where timber production may require special harvest methods, production rates, or other requirements to benefit or mitigate resources other than timber.

SPECIES MANAGEMENT GUIDE - A guide for management of an indicator species in a particular area. The guide includes management direction, schedules for utilization, inventories, research, monitoring, and optimum cover/forage relationships for the long term.

SPECIES RICHNESS MANAGEMENT - A wildlife management strategy to maintain viable populations of all resident species.

SPOTTED OWL HABITAT AREA (SOHA) - A habitat area designated to support one pair of owls. A dedicated SOHA does not allow scheduled timber harvest on otherwise suitable timber lands

SPRING BREAK-UP - Time of year when roads are damaged or "break up" due to melting frost and ice, generally from first of March to middle of April.

STAND - Timber possessing uniformity as regards to type, age class, risk class, vigor, size class, and stocking class.

STANDARD - A principle requiring a specific level of attainment, a rule to measure against.

STANDARD TIMBER COMPONENT - That part of the planned timber harvest area and volume of normal or "standard" sawlog production Used in Timber Management Plans.

STOCKING - The degree of occupancy of land by trees as measured by basal area or number of trees as compared to a stocking standard

STORET - The acronym for a computerized water quality data base operated nationwide by the U.S. Environmental Protection Agency.

STRATEGIC MINERALS - Those minerals of which the U.S imports 50 percent or more from foreign sources (based on 1978 U.S. Bureau of Mines figures).

STREAM CLASS - Classification of streams based on the present and foreseeable uses made of the water, and the potential effects of on-site changes on downstream uses. Four classes are defined

Class I - Perennial or intermittent streams that provide a source of water for domestic use; are used by large numbers of fish for spawning, rearing or migration; and/or are major tributaries to other Class I streams.

Class II - Perennial or intermittent streams that are used by moderate though significant numbers of fish for spawning, rearing or migration; and/or may be tributaries to Class I streams or other Class II streams

Class III - All other perennial streams not meeting higher class criteria

Class IV - All other intermittent streams not meeting higher class criteria.

STREAMSIDE MANAGEMENT UNIT (SMU) - An area of varying width adjacent to a stream where practices that might affect water quality, fish and other aquatic resources are modified to meet water quality goals, for each class of stream.

SUB-BASIN - Further subdivision of the Columbia Basin for the Wenatchee N.F. (Chelan, Entiat, Wenatchee and Yakima Sub-basins).

SUBWATERSHED - A part of a whole watershed. As used in this Forest plan: the part of a WATERSHED that lies within the boundary of the Wenatchee National Forest.

SUBSTANTIVE COMMENT - A comment that provides factual information, professional opinion, or informal judgement germane to the action being proposed

SUCCESSIONAL STAGE - A stage or recognizable condition of a plant community that occurs during its development from bare ground to climax For example, coniferous forests in the Blue Mountains progress through six recognized stages: grass-forb; shrub-seedling, pole-sapling; young; mature, old growth.

SUITABILITY - The appropriateness of applying certain resource management practices to a particular area of land, as determined by an analysis of the economic and environmental consequences and the alternative uses foregone. A unit of land may be suitable for a variety of individual or combined management practices. (36 CFR 219.3)

SUPPLY - The amount of an output that producers are willing to provide at a specific price, time period, and condition of sale.

SUPPRESSION - The action of extinguishing or confining a fire

SURFACE RESOURCES - Renewable resources located on the earth's surface in contrast to ground water and mineral resources located below the earth's surface

SURFACE RUNOFF - Water that flows over the ground surface and into streams and rivers.

SUSTAINED YIELD OF PRODUCTS AND SERVICES - The achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forest System without impairment of the productivity of the land (36 CFR 219.3)

TARGETS - Output accomplishments assigned to the Forest by the Forest Service Regional Forester. A statement used to express planned results to be achieved within a stated period of time.

TEMPORARY ROAD --Any short-lived road not intended to be a part of the Forest development transportation system and not necessary for future resource management

TENTATIVELY SUITABLE FOREST LAND - Forest land that is capable of producing crops of industrial wood and: (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soil productivity or watershed conditions, (c) existing technology and knowledge provides reasonable assurance that it is possible to restock adequately within five years after final harvest; and (d) adequate information is available to project responses to timber management activities

THERMAL COVER - Cover used by animals to lessen the effects of weather, for elk, a stand of coniferous trees 12 meters (40 feet) or more tall with an average crown closure of 70 percent or more; for deer, cover may include saplings, shrubs, or trees at least 1.5 meters (5 feet tall) with 75 percent crown closure.

THREATENED SPECIES - Any species of animal or plant which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range and which has been designated in the Federal Register by the Secretary of Interior as a threatened species

TIERING - The coverage of general matters in broader environmental impact statements with subsequent, narrower statements or environmental analyses incorporating by reference the general discussions and concentrating solely on specific issues

TIMBER CLASSIFICATION - Forest land is classified under each of the land management alternatives according to how it relates to the management of the timber resource. The following are definitions of timber classifications used for this purpose.

1.**Nonforest**--Land that has never supported forests and land formerly forested where use for timber production is precluded by development or other uses.

2.**Forest**--Land at least 10-percent stocked (based on crown cover) by forest trees of any size, or formerly having had such tree cover and not currently developed for nonforest use.

3. Suitable--Commercial forest land identified as appropriate for timber production in the Forest planning process.

4. Unsuitable--Forest land withdrawn from timber utilization by statute or administrative regulation (for example, wilderness), or identified as not appropriate for timber production in the Forest planning process

5. Commercial Forest--Forest land tentatively suitable for the production of continuous crops of timber and that has not been withdrawn from timber utilization

TIMBER MANAGEMENT PLANS (TM PLANS) - Functional resource plans completed in 1963 for the Wenatchee Working Circle and 1969 for the Naches-Tieton Working Circle, which established a timber sale volume to be sold each year. They were not integrated resource plans which considered impacts to all other resources on the Forest.

TIMBER PRODUCTION - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees to be cut into logs, bolts, or other round sections for industrial or consumer use. For planning purposes, the term "timber production" does not include production of fuelwood. (36 CFR 219.3)

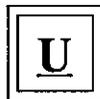

TIMBER STAND IMPROVEMENT (TSI) - The elimination or suppression of the less desirable vegetation in favor of the more desirable tree growth. It includes thinning, cleaning, weeding, and release cuttings.

TOLERANT SPECIES - Plants that grow well in shade

TOTAL SUSPENDED PARTICULATES (TSP) - Any finely divided material (solid or liquid) that is airborne with an aerodynamic diameter smaller than a few hundred micrometers

TRANSITORY RANGE - Land that is suitable for grazing use of a nonenduring nature over a period of time. For example, on particular disturbed lands, grass may cover the area for a period of time before being replaced by trees or shrubs not suitable for forage.

TURBIDITY - The degree of opaqueness, or cloudiness, produced in water by suspended particulate matter, either organic or inorganic. Measured by light filtration or transmission and expressed in Nephelometric Turbidity Units (NTU).

UNCERTAINTY - Whenever a variety of outcomes are possible and a probability of any specific outcome cannot be assigned with any degree of accuracy

UNDERSTORY - Vegetation growing under a higher canopy.

UNEVEN-AGED MANAGEMENT - The application of a combination of actions needed to simultaneously maintain continuous high forest cover, recurring regeneration of desirable species, and the orderly growth and development of trees through a range of diameter or age classes. This management must provide a sustained yield of forest products. Cutting is usually regulated by specifying the number or proportion of trees of particular sizes to retain within each area, thereby maintaining a planned distribution of size classes. Cutting methods that develop and maintain uneven-aged stands are single-tree selection and group selection. (36 CFR 219.3)

UNIFORM FLOW - A state of steady water flow where the mean velocity and cross sectional area are equal at all sections.

UNREGULATED TIMBER MANAGEMENT - Timber cut from those lands that are not organized to provide sustained yields of timber.

UNROADED ACRES - Those areas of undeveloped Federal land within which there are no improved roads maintained for travel by means of vehicles intended for highway use.

UTILIZATION STANDARDS - Standards guiding the use and removal of timber which is measured in terms of diameter at breast height (d.b.h.), top diameter inside the bark (top d.i.b.), and percent "soundness" of the wood.

UTILITY AND TRANSPORTATION CORRIDORS - A strip of land designated for the transportation of energy, commodities, and communications by railroad, state highway, electrical power transmission (69 KV and above), oil and gas and coal slurry pipelines 10 inches in diameter and larger, and tele-communication cable and electronic sites for interstate use. Transportation of minor amounts of power for short distances, such as short feeder lines from small power projects including geothermal or wind, or to serve customer subservice substations along the line, are not to be treated within the Forest Plan effort.

VARIETY CLASS - A classification system for establishing three visual landscape categories according to the relative importance of the visual features. Those with the most variety of diversity have the greatest potential for high scenic value. The three variety classes are: *distinctive, common and minimal*.

VERTICAL DIVERSITY - The diversity in a stand that results from the complexity of the above ground structure of the vegetation; the more tiers of vegetation or the more diverse the species make up (or both), the higher the degree of vertical diversity. This concept is close to but not exactly the same as "uneven-aged management," although each may influence the other. Application of even-aged management, for example, can be designed to accomplish vertical diversity objectives.

VIALBE POPULATION - A population which has adequate numbers and dispersion of reproductive individuals to ensure the continued existence of the species population on the planning area.

VIEWSHED - The total landscape seen or potentially seen from all or a logical part of a travel route, use area, or water body.

VISITOR INFORMATION SERVICE (VIS) - Activities which interpret for visitors, in layman's language, Forest management, protection, utilization, and research. It also includes interpretation of local botany, geology, ecology, zoology, history, and archaeology.

VISUAL MANAGEMENT SYSTEM - The management system used to protect and enhance the visual resource

VISUAL QUALITY OBJECTIVES (VQO's) - Categories of acceptable landscape alteration measured in degrees of deviation from the natural-appearing landscape. These categories include Preservation, Retention, Partial Retention, Modification, and Maximum Modification.

VISUAL RESOURCE (FOREST SCENERY) - The composite of basic terrain, geologic features, water features, vegetative patterns, and land-use effects that typify a land unit and influence the visual appeal the unit may have for visitors.

VQO - An abbreviation of visual quality objective.

WATER QUALITY - The biological, physical, and chemical properties of water that make it suitable for given specified uses. Different instream conditions of levels of water quality are needed to support different beneficial uses.

WATER YIELD - The measured output of the Forest's streams.

WATER YIELD INCREASE - Additional water released to Forest streams as a result of Forest management activities.

WATERSHED - The entire land area that contributes water to a drainage system or stream.

WETLANDS - Areas that are inundated by surface or ground water with a frequency sufficient to support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction (Executive Order 11990.) Under normal circumstances the area does or would support a prevalence of vegetative or aquatic life.

WFUD'S - An abbreviation of Wildlife and Fish User Days

WILD AND SCENIC RIVERS - Those rivers or sections of rivers designated as such by congressional action under the 1968 Wild and Scenic Rivers Act, as supplemented and amended, or those sections of rivers designated as wild, scenic, or recreational by an act of the Legislature of the State or States through which they flow Wild and scenic rivers may be classified and administered under one or more of the following categories:

1. Wild River Areas--Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America

2. Scenic River Areas--Those rivers or sections of rivers that are free of impoundments, with watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads

3. Recreational River Areas--Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

WILDERNESS - Areas designated by congressional action under the 1964 Wilderness Act Wilderness is defined as undeveloped Federal land retaining its primeval character and influence without permanent improvements or human habitation. Wilderness areas are protected and managed to preserve their natural conditions, which generally appear to have been affected primarily by the forces of nature, with the imprint of human activity substantially unnoticeable; have outstanding opportunities for solitude or for a primitive and unconfined type of recreation; include at least 5,000 acres or are of sufficient size to make practical their preservation, enjoyment, and use in an unimpaired condition; and may contain features of scientific, educational, scenic, or historical value as well as ecologic and geologic interest.

WILDERNESS RECREATION OPPORTUNITY SPECTRUM (WROS) --The Wilderness Recreation Opportunity Spectrum is an extension of the Recreation Opportunity Spectrum into Wilderness There are four classes; *Pristine, Primitive, Semi-Primitive and Transition* The *Primitive* and *Semi-Primitive* WROS classes correspond very closely to the *Primitive* and *Semi-Primitive Non-Motorized* classes in ROS The *Pristine* WROS class is the most undisturbed, natural portion of a primitive area. The *Transition* WROS class is essentially a *Semi-Primitive* WROS class area with greater allowances for social and biological influences of humans

WILDFIRE - Any wildland fire not designated and managed as a prescribed fire within an approved prescription.

WILDLIFE AND FISH USER DAY (WFUD) - One WFUD consists of 12 hours of recreation use that is the result of fish or wildlife

WINTER RANGE - The area available to and used by big game through the winter season.

WITHDRAWAL - An order removing specific land areas from availability for certain uses

WORKING CIRCLE - A geographic division of the Forest created for administrative or marketing purposes. The Wenatchee Working Circle in the Timber Management (TM) plans includes Chelan, Entiat, Lake Wenatchee, Leavenworth, and Cle Elum Ranger Districts. The Naches-Tieton Working Circle includes the Naches Ranger District.

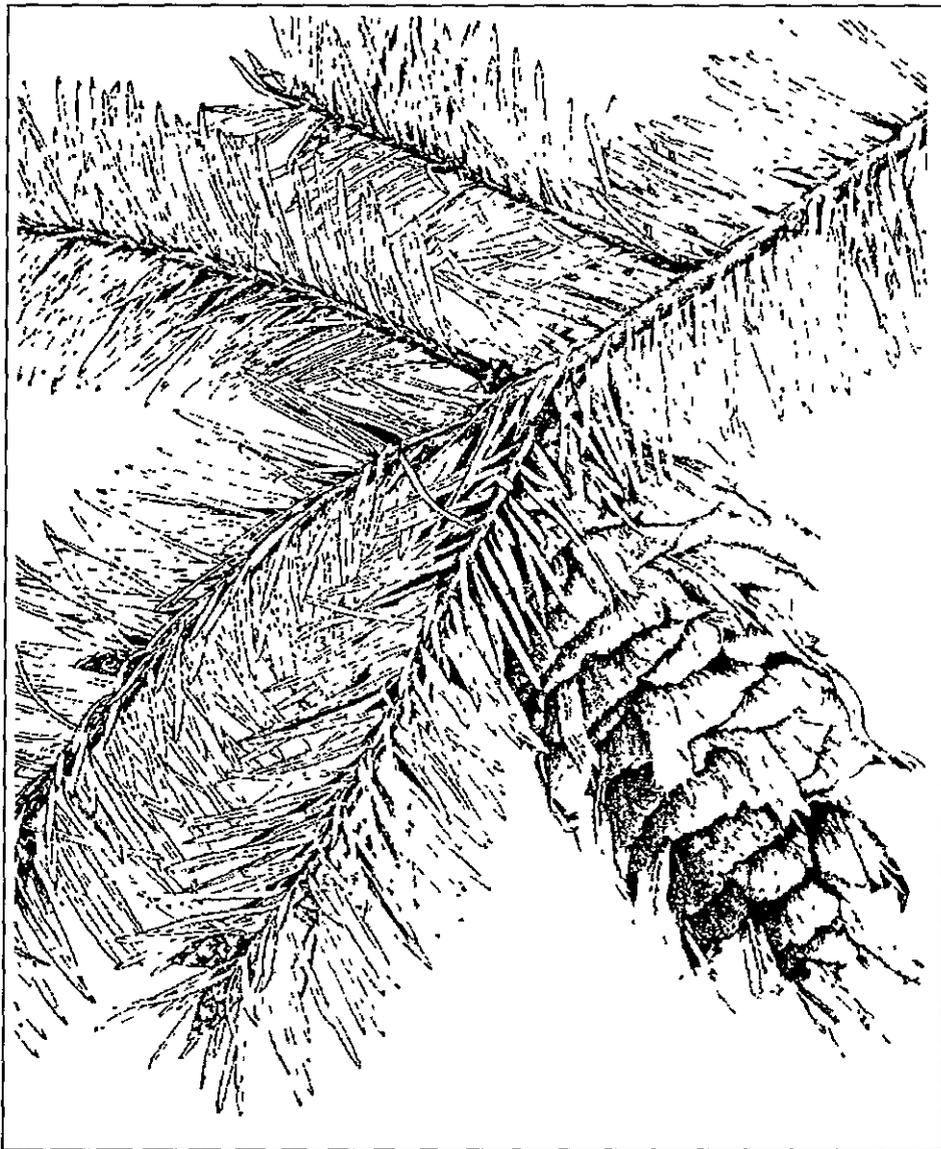

Y

YAKIMA INDIAN TREATY RIGHTS AREA - Those lands on the Wenatchee National Forest where the Yakima Indian Nation retained certain use rights under Article 3 of the Yakima Indian Treaty of 1855.

YIELD TABLES - Tables that estimate the level of outputs that would result from implementing a particular activity, yield tables can be developed for timber volumes, range production, soil and water outputs, and other resources.

Z

ZONE OF INFLUENCE - The geographic area whose social, economic and/or environmental condition is significantly affected by changes in Forest resource production or management.

FEIS INDEX

- AIR/AIR QUALITY** II-3, II-162, II-163, III-104, CH. IV: 39, 103-106, 110, 137-139
- ALLOWABLE SALE QUANTITY (ASQ)** CH. II: 9, 33, 41, 50, 58, 67, 76, 85, 94, 103, 111, 126, 127, 156, 174, 175, 176; III-78; CH. IV. 15-17, 63, 64, 66
- ALPINE LAKES MANAGEMENT AREA** I-4, I-5, CH. II: 3, 4, 5, 17, 19, 23, 29, 32, 39, 49, 56, 62, 66, 69, 71, 75, 80, 83, 93, 102, 107, 109, 124, 146, 162, 163, 190; CH. III. 4, 19, 20, 21, 35, 36, 37, 38, 40, 90, 104, 107, 133; IV-6, IV-35, IV-123, IV-140
- ANADROMOUS FISH** I-9; CH. II: 9, 33, 40, 50, 57, 67, 76, 84, 94, 103, 110, 126, 127, 151, 168, 169, 185, 186-192; CH. III. 57-62; CH IV: 51-56, 130
- ANALYSIS AREA** II-13
- ANALYSIS OF THE MANAGEMENT SITUATION (AMS)** I-4
- BALD EAGLE** II-153, III-42; IV-48, IV-49, IV-50, IV-77, IV-133
- BELOW-COST TIMBER SALES** III-71, III-72, III-73
- BENCHMARKS** CH. II: 3, 4, 16, 17, 21, 139, 175, 176
- BEST MANAGEMENT PRACTICES (BMP's)** CH. II: 2, 6, 21, 33, 40, 50, 57, 67, 76, 84, 94, 103, 110, 126, 127; CH. IV: 51, 53, 56, 102, 103, 132
- BIG GAME** CH. II: 25, 29, 32, 40, 49, 57, 66, 75, 84, 93, 102, 110, 124, 125, 139, 140, 172, 173, 183, 184, 186-192; CH. III: 49-53; CH. IV: 29, 40, 41, 44-47, 73, 74, 109, 130
- BIGHORN SHEEP** III-46; IV-47
- BIOLOGICAL DIVERSITY** II-141, II-172, II-173; III-63; CH. IV. 2, 58, 59, 65, 66-71, 80-83
- BUDGET** I-4; CH. II: 11, 27, 35, 43, 52, 60, 69, 78, 87, 96, 105, 160, 180
- CHECKERBOARD OWNERSHIP (ALSO SEE INTERMINGLED OWNERSHIP)** II-122, II-123, II-136, II-137; CH. III 4, 5, 29, 74, 76, 97, 98, 99, 102, 103, 140; IV-36, IV-123
- CHELAN COUNTY (SEE COUNTIES)**
- CHINOOK SALMON** II-151, II-152, CH III: 57-62;
- CLEARCUTTING** I-8; CH. II: 3, 26, 34, 41, 51, 58, 68, 77, 85, 94, 104, 111, 157, 175, 176; III-71, IV-6, IV-66, IV-89
- CLIMATE** III-3
- COHO SALMON** CH. III. 57-60, 62,
- COMMUNITY EFFECTS (SEE SOCIAL AND ECONOMIC EFFECTS)**
- COUNCIL ON ENVIRONMENTAL QUALITY (CEQ)** I-2, I-4, II-18

COUNTIES:

Appendices A-J

Final Environmental Impact Statement

Land and Resource
Management Plan

Wenatchee National Forest

APPENDICES PREFACE

These appendices supplement the information provided in the Final Environmental Impact Statement for the Forest Management Plan, for the Wenatchee National Forest. They support the discussion which describes the flow of the analysis from the Issues, Concerns, and Opportunities to benchmarks to alternatives to effects.

The appendices provide the reader who is looking for more depth a more detailed description of how alternatives were developed, how the alternatives and benchmarks were analyzed, what standards and guidelines are used for all alternatives, specific information about special areas, and other information which was used in writing the main FEIS body but was too extensive to be included.

ISSUES, CONCERNS, AND OPPORTUNITIES

IDENTIFICATION PROCESS

I. ISSUES, CONCERNS, AND OPPORTUNITIES

The public issues, management concerns, and development opportunities (ICO's) were identified over the entire period that the Land and Resource Management Plan was being developed. The process started in the spring of 1979 when a Forest list of ICO's was developed from previous public comments on Unit Plans. From May 1 through May 14, four workshops were held at central points on the Forest to involve Ranger Districts, Technical Work Centers, and Forest staff in the development of management concerns for the Forest. These concerns were summarized and refined at a meeting with the Forest Management Group on May 17, 1979. This resulted in the identification of 85 tentative issues. In June 1979, the tentative issues were published in Wenatchee Forest Plan Report 1 and sent to more than 2,400 people including a wide variety of interested citizens, interested groups, and State, County, and Federal agencies, Indian tribes, and private industry in Washington.

Specific contacts were made with County officials and planners for Chelan, Kittitas, and Yakima Counties, Washington. The tentative ICO's were also discussed with the Washington Departments of Fisheries, Wildlife, and Transportation as well as various Federal agencies such as the Soil Conservation Service, Bureau of Land Management, U.S. Fish and Wildlife Service, and the National Park Service. Other personal contacts were made with representatives of the Yakima Indian Nation, Colville Confederated Tribes, local private industrial timber managing companies and any interested groups--wildlife, sportsmen, or conservation.

The purpose of these meetings was two-fold:

1. To obtain input on the tentative planning Issues and Concerns.
2. To help ensure compatibility and consistency between local plans of others and the developing Wenatchee National Forest Plan through continuing dialogue and coordination.

Public workshops were held at key areas in the Forest's influence zone including Wenatchee, Yakima, Seattle, and Tacoma. The Seattle and Tacoma workshops were co-hosted by the Mt. Baker-Snoqualmie and Wenatchee National Forests. One hundred fifty-eight (158) people attended the workshops and 230 sent written responses. All of the potential issues were screened using the following criteria to determine their applicability to the Forest planning process:

1. Intensity of public issue or management concern - High.
2. Scope - Forest-wide or greater.
3. Duration - Long term.
4. Feasibility of solution in the Forest Plan - Feasible.
5. Future options - Decreasing.

Individual issues were lumped as facets of major issues whenever practical. Based on this analysis, a revised list of issues was mailed in October 1979 to more than 1,900 people including the public, Government agencies, and Indian tribes (Forest Plan Report 3). This listed 13 central issues with 27 questions to be addressed in the planning process.

In December, 1984, the Issues and Concerns were reviewed and updated. The revised issues were rewritten to include a discussion of the "opportunities" offered by the Forest Plan for resolving the issues. Three new issues were added: one dealing with the cumulative effects of Forest management activities, one concerning the recent mining interest on the Forest, and one relating to the management of prehistoric cultural resources.

The revised ICO's were mailed to more than 2,300 people on the Forest Plan mailing list in December, 1984. One hundred written responses were received. Based on this response, the ICO's were again revised. A new issue about the social and economic implications of the alternatives was added to the existing 15 issues in response to public comments on this subject.

II. CONSULTATION WITH OTHERS

Consultation with other agencies, local governments, interest groups, and individuals occurred throughout the planning process. Several interest groups tracked the planning process on a regular basis. Meetings were held to discuss specific concerns that surfaced over technical aspects of the planning data. Meetings were also held with any group that wanted to learn more about the planning process.

For instance, the Forest held meetings with the Yakima Indian Nation Tribal Council at various times to discuss the planning process and various issues such as rights under Article 3 of the Yakima Indian Treaty, the American Indian Religious Freedom Act, and the Forest's management of prehistoric cultural sites. The Forest and Washington Departments of Fisheries and Wildlife also held meetings to coordinate the Forest's and Department's planning efforts. The Forest biologist worked with the various State and Federal wildlife agencies to coordinate their respective plans with the Forest's planning process.

The Forest held four public meetings at various locations in central Washington from January through March of 1985. About 350 people attended the meetings. Attendance was as follows: Wenatchee--70, Yakima--125, Ellensburg--100, and Pasco--55. In addition, meetings were held with the Yakima Indian Nation Council and the County Commissioners of Chelan, Kittitas, and Yakima Counties. The purposes of the meetings were to share information on the status of planning, encourage public participation in the next major planning step (The Draft Environmental Impact Statement), and solicit concerns about planning to date.

The ICO's which had been developed for the Draft EIS were ratified again through extensive public comment received after publication of the DEIS and Proposed Forest Plan in June 1986, and the Supplement to the DEIS in October 1988. For the DEIS and proposed Plan, the Forest had a 120 day review period during which it received over 4,665 responses.

Eleven public meetings were held to give information and receive public input on the Draft planning documents. About 520 people attended the meetings. Attendance was as follows: Wenatchee--70, Chelan--30, Ellensburg--70, Entiat--38, Leavenworth--33, Seattle--53, Tacoma--25, Cle Elum--55, Yakima--90, Richland--30, and Lake Wenatchee--25. Presentations were also made to 164 people of eight different organizations. The Supplement to the DEIS had a 90 day review period and received about

2,650 responses. Eight public meetings were held for the Supplement. Attendance was as follows: Entiat--28, Lake Wenatchee--57, Wenatchee--32, Seattle--13, Cle Elum--12, Ellensburg--11, Leavenworth--50, and Yakima--16.

Several issues or aspects of issues received fresh emphasis after the issuance of the Draft in 1986 and the Supplement in 1988. Numerous meetings with interested agency officials, groups, and individuals since then have continued to clarify the ICO's. Appendix K describes the public involvement between the DEIS and FEIS. It also displays the public comments received and responses to the comments.

III. SELECTED ISSUES, CONCERNS, AND OPPORTUNITIES

In this section, the issues selected through the public involvement process are listed along with the opportunities each issue presents. There is little differentiation between issues and concerns. The management concerns were displayed to the public and many of them were adopted by the public as issues. Former Issue #13, "Allocation of Areas Designated for Further Planning by RARE II", is now included with Issue #2, "Management of Areas that are Presently Unroaded". New issue #13, "Minerals," was in the tentative list of issues. Recent mining activity near Wenatchee has boosted the significance of this issue. Other issues added to the original list include #14, "Cultural Resource Management," and #15, "Cumulative Effects." These issues were added because of continuing and intensifying concerns by the public and/or management. Issue #16, Social and Economic, was added as a result of public response to the revised ICO's in 1985. Issues #17 and #18, Wild and Scenic Rivers and Old Growth, were added as a result of public input to the Draft EIS, Proposed Forest Plan, and Supplement to the DEIS.

1. Recreation Opportunities and Use Conflicts

The Forest receives about 5 million visitor days of use a year. The Forest is one of the heaviest recreation-oriented Forests in the Pacific Northwest Region. Use is continuing to increase, and conflicts between recreational user groups (off-road vehicles, hikers, horses, snowmobilers, cross-country skiers, etc.) are becoming more evident. For instance, there are concerns about noise pollution from off-road-vehicles in narrow canyons, such as Devil's Gulch, the Teanaway, and the Lake Clara areas. In addition, some recreation activities can cause resource damage because of the level, type, or location of use. The use of ORV's received one of the largest volumes of comment to the DEIS with the majority opposed to ORV use in general, and especially to any expansion of use. There is also a demand to separate different types of recreation use by areas. Regulation of commercial use is included in the issue.

Recreational use in key wildlife habitat areas at certain times of the year in such places as Swakane Canyon and the Oak Creek Game areas may disrupt wildlife. Timber harvest access roads can increase roaded dispersed recreation opportunities but reduce primitive and semi-primitive recreational opportunities. The potential effect of the alternatives on trails and trail mileage is also an issue.

Opportunities

There are opportunities to reduce user conflicts by separating uses through land allocations: scenic areas, unroaded dispersed recreation areas, areas for motorized or non-motorized use, and classified Scenic or Recreational Rivers are all possible. It is also possible to eliminate or reduce damage of conflicts through information programs and by applying seasonal or year-long restrictions on uses of trails or areas where appropriate.

Management activities such as danger tree removal, thinning, or timber removal for ski runs are opportunities to compliment developed recreation management. In some instances, it may be desirable to remove diseased or fire damaged trees from recreational areas. In other instances, this would be inappropriate.

The Forest has an opportunity to develop or expand recreation sites, such as Johnny Creek, and ski areas, such as Mission Ridge and White Pass. There are opportunities for user groups to assist in the planning, construction, and maintenance of recreation trails and the maintenance and care of backcountry areas. There are also opportunities to contract with the private sector for recreation site development, operation, and maintenance, such as the Fields Point parking area and concession. There is an opportunity to use project design to encourage reconstruction of recreational trails when timber is harvested.

2. Management of Areas That Are Presently Undeveloped.

There are 556,272 acres of the Forest outside of the wilderness which are presently within inventoried roadless areas.

Name of Roadless Area	Location Ranger District (s)	Net National Forest Acres
Myrtle Lake	Entiat	10,918
Rock Creek	Lake Wenatchee	32,924
Twin Lakes	Lake Wenatchee	22,048
Canyon Creek	Lake Wenatchee	9,158
Heather Lake	Lake Wenatchee	11,067
Chelan	Chelan	71,063
Entiat	Entiat	71,254
Stormy	Chelan, Entiat	32,500
Slide Ridge	Chelan	10,091
Devil's Gulch	Leavenworth	25,186
Taneum	Cle Elum, Naches	25,122
Manastash	Cle Elum, Naches	8,798
Norse Peak Adjacent	Naches	11,300
Quartz	Naches	8,756
Naneum	Cle Elum	6,911
Lion Rock	Cle Elum	4,834
William O. Douglas Adj.	Naches	22,938
Blue Slide	Naches	18,571
Goat Rocks Adjacent	Naches	7,357
Nason Ridge 1/	Lake Wenatchee	19,123
Alpine Lakes-Adjacent 1/	Lake Wenatchee, Leavenworth	44,393
Thorp Mountain 1/	Cle Elum	15,667
Teanaway 1/	Cle Elum	66,293
TOTAL		556,272

1/ Located within Alpine Lakes Management Area.

Some areas could continue to be managed in a roadless condition, while others could be roaded to provide easier access for the enjoyment of scenic and recreational values as well as for the development of other resources. Areas which can provide unroaded types of recreation, both motorized and non-motorized, are becoming more scarce. People are concerned about how much of these areas should be managed for timber as opposed to management for roadless recreation and wildlife and wildlife habitat. This issue also received a very large volume of comment to the DEIS with the majority in favor of preservation.

Others would like to see these areas roaded to provide scenic drives or campgrounds. There is also a concern about how quickly these areas should be entered and the effect roading and management activities have on soils, water quality, old-growth forests, and wildlife and plant species dependent on old-growth forests.

Opportunities

There is an opportunity to provide for a variety of uses in the presently undeveloped areas. These could include unroaded recreation, roaded recreation, commodity production, and special area classification. The selected use would determine which lands would be roaded and how soon roading might occur. There are opportunities to help meet national and regional targets for timber and mineral production.

There is also an opportunity to use roadless areas to help meet management goals or targets for research natural areas, endangered, threatened and sensitive plant and wildlife habitat, and old-growth stands for dependent species such as spotted owls. These land allocations could be made in wilderness or unroaded recreation areas rather than in timber management areas whenever possible. There are opportunities to maintain the future suitability of roadless areas as potential wilderness additions. There is an opportunity to maintain the management direction in the Alpine Lakes Area Land Management Plan in all alternatives. This Plan had extensive public involvement and is continuing to be tested.

3. Transportation System Development and Management

Transportation systems (roads, trails, helispots, etc.) are necessary for Forest management, protection, and use. Presently, there are an estimated 4,667 miles of roads on the Forest. About 18 percent of these roads are major access routes. There are also 2,581 miles of trails on the Forest. Basically, the main access roads are in place, but new local roads and trails will be needed; however, there is increasing concern over the ultimate extent, standards, and management of roads and trails. For instance, there are concerns about the proposed Naches Pass Road and whether or not it should be built. Management of the transportation system is largely determined by management direction for other resources. This issue relates to undeveloped areas, timber, and wildlife issues.

Opportunities

An opportunity exists to match the transportation system with the goals of the specific management area, so that they complement each other. In other words, road and trail standards and densities should be planned to meet the management goals of the area they serve. For instance, the Icicle River Road is paved part way to facilitate recreation use.

Road and trail locations, standards, and use can be coordinated with intermingled or neighboring private and public land owners to best serve the interests of all parties involved. This occurs in such areas as the Taneum-Manastash, Little Naches, Icicle River, and Coulter Creek areas.

4. Water Quality and Quantity

The Forest currently produces more than 4.4 million acre feet of water runoff annually. A number of cities and towns near the Forest use water coming from National Forest lands for domestic purposes. This use will increase as communities grow, and the demand for sediment-free irrigation water will increase as new lands are cultivated. At the same time, increases in most uses (recreation, timber management, roading) will make it more difficult to maintain water quality and meet the demands for increased water quantity. The maintenance of enough clean, cool water for human use and fish and wildlife needs is a fundamental concern. An issue here also is protection of water quality and anadromous fish habitat. It is also important to assure that Forest responsibilities regarding the Yakima Indian Treaty fishing rights are met.

Opportunities

Riparian zone (streamside) management provides the opportunity to enhance wildlife, recreation, scenic values, and fishery habitat by providing hiding and thermal protection and minimizing ground disturbance while at the same time protecting water quality and soil productivity through use of Best Management Practices (see BMP Appendix J). There are also opportunities to improve the condition of some of the watersheds on the Forest.

5. Mixed Ownership Management

The land encompassed by the Forest boundary includes 2,457,379 acres. Of this, about 12 percent, or 293,199 acres, is managed by the Bureau of Land Management, Washington State, and private landowners. Much of this land is scattered throughout the Forest and occurs in "checkerboard" patterns in the Interstate 90 and Highway 2 corridors. Management philosophies, practices, and goals of other owners sometimes differ from those of the Forest Service. This can directly affect management options on National Forest land, influencing roading decisions, timber harvest scheduling, and scenery.

There are also concerns about the development of second homes or permanent residences (urban/wildland interface) near or within the Forest boundary (Rimrock, Number Two Canyon, Nahahum Canyon, Icicle River, Lake Wenatchee) and the resulting fire protection, road use, and water quality implications. The other issues that are involved include water quality maintenance and management of timber, recreation, wildlife management, and scenic values.

Opportunities

Opportunities exist to consolidate National Forest ownership for more effective management. There are less property line surveys, permits, and coordination meetings needed when lands are consolidated. There are also opportunities to better coordinate Forest plans and activities with neighboring intermingled landowners (Longview Fibre Co., Plum Creek Timber Co.) and local county governments in Chelan, Kittitas, and Yakima Counties.

6. Wilderness Management

Almost 39 percent, (841,034 acres) of the Wenatchee National Forest is classified as wilderness.

Name of Wilderness	Location Ranger District (s)	Net National Forest Acres
Lake Chelan-Sawtooth	Chelan	56,414
Glacier Peak	Chelan, Entiat, Lake Wenatchee	289,001
Henry M. Jackson	Lake Wenatchee	27,221
Alpine Lakes	Lake Wenatchee, Leavenworth, Cle Elum	244,057
Norse Peak	Naches	36,295
William O. Douglas	Naches	151,730
Goat Rocks	Naches	36,316
Total		841,034

This includes the 340,795 acres recently added to wilderness on the Forest through the Washington State Wilderness Act of 1984. The Washington Wilderness Act added land to the existing Glacier Peak and Goat Rocks Wildernesses and created the Lake Chelan-Sawtooth, Henry M. Jackson, Norse Peak, and William O. Douglas Wildernesses. Use in wilderness is increasing, and user conflicts (horse vs. hiker) and resource problems are occurring more frequently. The main issue is the Forest's ability to protect the wilderness environment and minimize conflicts between competing uses. Regulation of commercial use is also important.

The primary concern is recreation overuse along main trails and at destination sites in wilderness including vegetative disturbance and water pollution from people and/or recreation stock. Such impacts have occurred at Buck Creek Pass and Lyman Lake in the Glacier Peak Wilderness, the Enchantments in the Alpine Lakes Wilderness, and Shoe Lake in the Goat Rocks Wilderness.

Opportunities

There are opportunities to inform the public of proper use of the wilderness through techniques such as "no trace camping" and dispersion of use. Deteriorated campsites can be revegetated and trails relocated to avoid such problems. There are many opportunities for the public to become actively involved in the care and maintenance of the wilderness, including trail maintenance, litter patrol, and education of peers or children. There are also opportunities to provide for quality wilderness experiences for the public through permitted commercial outfitting and guiding.

There is an opportunity to allow fire to play a more natural role in the maintenance of the wilderness ecosystem. There is also an opportunity to inform the public of the past grazing history in these areas and the advantages to continuing this use where appropriate.

7. Wildlife and Fish

The Wenatchee Forest sustains a wide variety of fish and wildlife species because of its variety of habitats. Activities that affect habitat (trees, grass, shrubs, soil, and water) can have a direct influence on fish and wildlife. This issue includes the maintenance and management of essential habitats and maintenance or enhancement of animal diversity. The issue also involves identification and protection of threatened and endangered species and recognition of wildlife needs for old-growth forest stands. Management activities that affect fish and wildlife habitat are timber harvest, recreation, livestock

grazing, road management, and fire management. Small hydroelectric projects and irrigation impoundments may alter the quantity and quality of available fish habitat. This issue includes maintaining habitat quality for anadromous fish, although the existing habitats are now generally underutilized. The presumption is that, as a result of the Fish and Wildlife Program of the Pacific Northwest Electric Power Planning and Conservation Act of 1980, anadromous fish levels should increase to fully utilize the existing habitat.

Water quality may often limit the Forest's fisheries production potential. For instance, most of the streams exhibit very low year-long water temperatures due to their high altitude and their minimal nutrient content which results in slow fish growth. Also, there is the potential in some areas for high in-stream temperatures during short periods of the summer mostly due to past timber harvest activities.

Opportunities

There are opportunities to manage key habitat specifically for wildlife, (e.g., winter ranges, old-growth,) and for fish (e.g., riparian protection zones) through management area designations. There are opportunities to work more closely with the Washington State Department of Wildlife and Fisheries, the United States Fish and Wildlife Service, and the Yakima Indian Nation, to improve the management of fish and wildlife habitat on the Forest.

There are additional opportunities to:

Wildlife

- Improve habitat for big game.
- Improve browse production and quality on winter ranges.
- Develop and implement Forest standards and guidelines for the management of snags, down logs, and brush piles for wildlife.
- Provide structural habitat improvements such as water developments and nest platforms in snag deficient areas for birds of prey.
- Provide, where possible, habitat mitigation, rehabilitation, or enhancement for fish and wildlife through the use of range betterment funds, Knutson-Vandenberg funds, timber harvest design, or fuels treatment.
- Better balance livestock and wildlife range use by implementing improved range management and range rehabilitation practices.

Fisheries

- Manage habitat to maximize stream productivity. This includes controlling sediment, influencing high or low water temperatures, artificially adjusting pool to riffle ratios, and managing large woody debris and streamside vegetation.
- Remove barriers to spawning and rearing habitat for anadromous and resident fish.
- Assure that road crossings of streams do not obstruct upstream fish passage and that road and timber harvest activities do not cause damage to the riparian habitat.

--Improve habitat for anadromous fish to compliment the implementation of the Columbia Basin Fish and Wildlife Program and the Yakima River Water Basin Enhancement Project.

--Develop fish stocking plans with the fisheries agencies to optimize use of aquatic habitats, especially for high altitude lakes.

8. Management of Scenery

The Forest is well known for its sweeping vistas, variety in topography, ecotypes, life forms, and overall natural appearing environment (e.g. White, Chinook, and Stevens Pass). About 13 percent of the recreational use on the Forest is driving for pleasure and viewing scenery. As more demands are placed on the Forest for timber and other uses, it becomes more difficult to maintain a pleasant forest atmosphere and natural appearing environment. Timber management can compliment the scenic resource, and visual management can compliment wildlife habitat and recreation management. The issue involves the degree of protection scenic values should be given and the cost and impacts of visual management on other Forest activities, i.e., *reduction in the annual timber harvest and the resulting cost of implementing visual management activities.*

Opportunities

There are opportunities to compliment other management goals through the creative management of Forest scenery.

There are also opportunities to maintain and enhance the scenic quality of the major travel corridors. There is an opportunity to rehabilitate previously modified landscapes for improved scenic values.

9. Timber Management

Timber management is a major activity on the Forest. The ten-year (1977-1986) average harvest was 162 million board feet per year. The need for lumber and fiber is expected to stay about the same as the last decade's average in coming years. At the same time, increasing demands for other uses will add complexity to the task of timber management. For example, the recent addition of 340,795 acres of land to wilderness reduced the acreage available for timber management by about 51,500 acres. An additional 100,800 acres of previously deferred productive forest acres were also removed from future consideration for timber harvest.

This issue involves the determination of which of the tentatively suitable timberlands of the Forest are to be designated for timber management; the timber harvest level; and the effect timber management should have on other resources and multiple use objectives. People are concerned about the type and intensity of timber management practices necessary to increase timber production and growth, especially the role of clearcutting and pesticide use. There are also concerns about possible departures from the non-declining even flow timber harvest schedule. Timber harvest departure would accelerate harvest of old-growth stands. Comments to the DEIS concerning timber harvest levels were higher in number than any other subject. Most were in favor of increased harvest levels with the remaining voicing concerns about impacts of timber harvest on other resources.

Forest managers are concerned about maintaining or enhancing soil productivity. Timber harvest and slash treatment annually affect more National Forest land than any other activity, therefore, these activities are periodically monitored to ensure that impacts on the soil resource are within acceptable levels. Managers are most interested in improving soil productivity on those soils that show the best economic responses to applied management including rate of stocking, timber species, control of forest disease, tree improvement, and fertilization.

This issue involves other issues such as wildlife habitat, recreation opportunities, road densities, visual and cultural resource management, water quality, and range management. Timber management activities may be in competition with some of these issues such as the need for old-growth forest for dependent wildlife and the need for unroaded recreation areas.

Opportunities

There are opportunities to allocate the most suitable, productive timberlands, where management activities are most cost effective (such as Meadow Creek and the Little Naches) to intensive timber production. There are also opportunities to benefit other resources at little or no extra cost. This includes improvement of big game cover/forage relationships; development of temporary forage for wildlife and livestock; and selective timber removal to improve the visual condition of travel corridors, open views of surrounding landscapes, and promote vegetative diversity.

Another opportunity is the replacement of stands where the heaviest timber mortality and disease is occurring. Growth gains of up to ten percent can be expected by planting genetically superior seedlings rather than relying on trees from non-selected parents.

There is a sizeable existing and potential supply of cull timber material and small round wood which present marketing opportunities. The main source is defective logs and undersized wood resulting from logging residue. Precommercial thinning, disease and insect mortality, and stagnated stands also provide fiber sources. This material has a wide variety of present and potential uses for specialty building materials, energy production, pulp and fiber products, and home firewood.

10. Energy

An adequate supply of energy, as well as its conservation, is a high priority national objective. Forest lands play an important role in production and transmission of energy. Various types of energy resources exist on the Wenatchee National Forest. These include coal, hydroelectric power, and renewable forest products (wood and fiber). Energy resources also include potential oil and gas and geothermal resources.

The issue deals primarily with the extent, location, and availability of potential energy resources on the Forest and how they should be managed. The attainment of other resource goals in an energy conservative manner is a complimenting issue.

The resource conflicts associated with this issue are environmental concerns such as potential effects on water quality, instream flows, scenery, and special areas. Special areas include Research Natural Areas, cultural and historical sites, botanical, or scenic areas. It also includes the potential physical impacts of access roads, pipelines and transmission lines, such as on Stevens, Stampede, and Snoqualmie Passes, on commodity resources (e.g., timber and range).

Opportunities

There are opportunities to include additional transmission lines or pipelines within existing corridors. There is also an opportunity to plan needed access roads so that they serve multiple uses. Transmission lines can be located so that they have the least possible impact on forest scenery. Transmission line rights-of-way can provide products, such as Christmas trees, berries, forage, openings and edges for wildlife. There are opportunities to utilize wood fiber wastes for energy production while reducing fire hazard.

11. The Role of Fire

Fire was long considered the enemy of the Forest. For example, in 1970 about 130,000 acres of the Forest were burned by wildfire primarily in the Entiat Valley and Lake Chelan areas. However, excluding all fire from the Forest can have some undesirable consequences such as natural fuel build up, which may lead to more large scale fires in the future.

The issue deals with how and where to use prescribed fire as a tool to improve Forest conditions. It also considers the role naturally occurring fires should play in the Forest's management objectives.

This issue can have a complimentary relationship to wildlife habitat, timber management, and sometimes recreation management. There can be a conflict with the Clean Air Act, and current direction to allow fire to play a more natural role in the Forest may not be acceptable to some segments of the public.

Opportunities

If the timing, location, size, and frequency of fires can be controlled, then fire can be a tool to clean up natural fuels without damage to Forest resources while returning various ecosystems to a more natural condition.

There are opportunities to make more effective use of fire as a tool in wildlife, timber, and recreation management. Naturally occurring fires can also play a more effective part in maintaining ecosystems in wilderness and unroaded recreation areas. There is an opportunity to preplan and determine where fire can be used effectively to fulfill its role and to reduce the cost of fire management activities.

12. Range Management

Livestock grazing presently takes place on the Forest through grazing permits issued to 37 local livestock owners. Permitted livestock use has declined in recent years although it is still a significant activity on the Forest. As other uses have increased, potential conflicts with domestic grazing have become more apparent. At the same time, managers are concerned about development and management of grazing resources for use by livestock in the future.

Livestock grazing has the potential to conflict with recreation, water quality, wildlife, fish, and timber. When livestock use the same meadows, streams, and trails that recreationists use, conflicts may result. Livestock use of streamside (riparian) areas may cause damage from compaction of soils and reduced water quality from streambank disturbance. This issue received a large amount of comment to the DEIS, with most opposed to grazing on the Forest.

There may be competition between livestock and big game for available forage. Without careful management, concentrated livestock use can also result in the trampling of seedlings in young plantations and soil compaction.

Opportunities

Livestock grazing can compliment other activities including recreation, wildlife, and timber. Sheep grazing can retard brush growth in meadows and along trails. Wildlife forage areas can be maintained or improved through intensive grazing systems. Timber management activities such as clearcuts, partial cuts, and thinnings may provide temporary forage areas. Grazing use can also reduce brush and grass competition which will enhance tree establishment and growth.

13. Minerals

Mineral resource activities in the central part of the Wenatchee National Forest took a dramatic upturn in March 1983 following a major gold discovery in Dry Gulch, a few miles off the Forest near the city of Wenatchee. The response to this was the location of more than 6,000 lode claims on National Forest land in Chelan County and at least 1,000 new mining claims in Kittitas County. Forest Service managers predict an increased minerals work load over the first five years of the 10-year planning period as a result of industry exploration for metallic minerals (predominantly gold) and possible extraction activities.

In addition to the increased mining claim activity, there appears to be continuing interest in the oil and gas potential of the area. A total of more than one-half million acres of the Forest were leased for oil and gas exploration between 1979 and 1983. Of this total, the leases on nearly one-half of that acreage have terminated. As of February, 1985, however, there were still 79 existing oil and gas leases covering about 239,918 acres, while 94 oil and gas lease applications covering 365,491 acres were pending. To date, no exploratory wells have been drilled on the Forest. Off-Forest drilling in Yakima and Kittitas Counties has provided encouraging evidence, but only noncommercial quantities, of gas. The evidence encountered, however, will justify additional exploration and leasing activity, some of which may occur on Forest lands.

The issues expressed by the mining industry, as well as the recreational miner or hobbyist, are dominated by their concern that mineral potential lands will be allocated to uses which prohibit or severely limit exploration and mining opportunities. They are concerned that lands will be withdrawn from mineral entry, or unreasonable and costly constraints will be required in approved operating plans. Most of the comments to the DEIS repeated these concerns.

To the general public, the issue is the potential environmental impacts associated with exploration, extraction and processing operations, and whether successful mitigation and reclamation of those impacts on local communities would be successful, while others are especially concerned about possible air and water quality degradation.

Opportunities

By facilitating and encouraging mineral exploration and development activities, new mineral resources may be discovered and produced. Such development may not only improve the employment and economic condition of local communities, but the commodity produced may contribute to improvement in our national trade situation. When mining does occur, existing regulations ensure environmental impacts are minimized, undue degradation is prevented, and appropriate reclamation is successful. Through proper planning, reclamation objectives may be designed to benefit the management of other resources once the mining activity ceases.

14. Cultural Resource Management

There is an ongoing program to identify and evaluate the historic and prehistoric cultural resources which exist on National Forest lands. To date, over 500 cultural resource sites (archaeological sites, historic structures, etc.) have been reported within or adjacent to the Wenatchee National Forest. These sites represent a broad cross-section of uses, spanning a period of several thousand years. Decisions about how best to manage these sites relate to such issues as historic significance, local community interest, American Indian concerns, accessibility, compatibility with other management activities, and recreational, research, or interpretive values.

As land-modifying activities and public use increase within the Forest, so does the possibility of loss or degradation of the cultural resources. The degree of potential impact will depend upon the location and extent of land alteration, the nature of the site, and the concentration of public use. In these instances, appropriate mitigation methods may be necessary to reduce or eliminate the undesirable effects or to recover the historic values of the properties prior to their alteration. The most desirable management strategies, however, are those which effectively protect the site in place, are economically prudent, and are compatible with other resource management needs and uses. A central concern is to provide a balance between these other uses and the protection of cultural sites so as to provide adequately for their preservation.

Opportunities

Several opportunities exist in the management of cultural resources. Timber harvesting can compliment the cultural resource program by providing opportunities for the identification of previously unknown cultural properties. Field reconnaissance accelerates in proportion to the number of acres scheduled for harvesting. In addition, in heavily vegetated environments, removal of the understory and organic duff layer may provide the only means of locating archaeological sites (Lake Wenatchee, for instance).

Recreational use increases opportunities for interaction between the public and cultural resources. Interpretive programs through which the Forest visitor can both enjoy and appreciate the cultural resources can be planned and developed with community involvement. One such area is the Stevens Pass Historic District. An active effort to solicit public opinion well in advance of the development of a management direction for an area or property could help to define the level of anticipated demand for its use and preservation.

There is also an opportunity, in those instances where on-site preservation is not possible, to carry out data recovery which could contribute locally and regionally to significant research questions and, in some cases, could build a deeper awareness of the contributions of American Indians to the public heritage.

15. Cumulative Effects

“Cumulative effects” is a term which has been developed to describe the collective long-term environmental impacts which result from natural processes and human activities within a forest area. The principal areas of concern are the cumulative impacts of timber harvest activities on watersheds (soils, water quality, or quantity) and on fish and wildlife (numbers and habitat diversity). Other areas of concern are cumulative impacts on scenery and recreational resources. Any evaluation of the cumulative effects of activities on National Forest lands must consider the impacts of activities occurring on neighboring state and private lands as well. This is particularly important in areas of mixed ownership where timber harvest is occurring on private land, such as Cabin Creek near Snoqualmie Pass. Public comments to the DEIS on this issue were strongly concerned with the cumulative effects on soil and water.

Opportunities

There are opportunities to:

- a. Reduce negative cumulative impacts through timber harvest scheduling, coordination with other landowners, and land exchanges.
- b. Buffer the effects of accelerated timber harvest on adjoining ownership by delaying the timber harvest on National Forest system lands in sensitive drainages, such as Log and Cabin Creek on the Cle Elum District and Thompson Creek on the Leavenworth District.

16. Social/Economic

The Forest is primarily located in three central Washington State counties: Chelan, Kittitas, and Yakima. More than 250,000 people live in the three-county area (1983 Population Trends for Washington State). There are 16 cities within the three-county area that have more than 1,000 inhabitants. The Yakima Indian Nation occupies the southern part of Yakima County while the Colville Indian Reservation is 60 miles north of the Forest in Okanogan County.

Major basic industries of the three counties are agriculture, lumber and wood products, manufacture and services, and trade. Tourism and recreation are also important sources of revenue for the local economy. Total recreation use on the Forest in 1984 was about 4.5 million visitor days. The 1984 unemployment rate in the three-county area was 13 percent. This is more than 3 percent higher than the 9.5 percent average 1984 State-wide rate (Washington Employment Security Department, 1984).

Local mills are dependent on National Forest timber for 40-60 percent of their mill capacity. The ten-year average (1977-1986) timber harvest volume on the Forest was 162 million board feet per year. In 1983 a gold mine was developed near Wenatchee. Future gold mining exploration and mining is expected to be concentrated in Chelan and Kittitas Counties as a result of this discovery. Along with agriculture and recreation, these commodity producing activities affect the number of wholesale and retail positions, service and supply jobs, and much of the construction activity and other employment opportunities that occurs.

In as much as the local economy is based on commodities and recreation, residents are concerned as to the extent to which the Forest land uses will provide timber production, mining, and recreational opportunities which provide income. They are equally apprehensive regarding substantial changes in outdoor-oriented lifestyles. Many visitors live in or near the Forest while others must travel moderate distances (Seattle, Tacoma) to pursue their outdoor recreational interests.

Opportunities

There are opportunities to provide various levels of public benefits to local communities. There are opportunities to maximize revenues or stress benefits of wildlife habitat and recreation. There are also opportunities to strike a balance between commodity production and amenities.

17. Wild and Scenic Rivers Classification

Because of public input to the DEIS, the issue of Wild and Scenic Rivers was broken out into a separate topic. A total of 20 rivers were considered for an analysis of their eligibility. Some of these rivers were considered as suitable for classification and have received a preliminary administrative recommendation for classification.

There are concerns about what the effects of classification would have on timber harvest levels. The management of the scenic resource along the river and how it changes with the different proposed classifications is also a concern. A concern exists of which classification is most appropriate for specific segments of individual rivers. The major public concern is what effect classification would have on private lands within the river corridors.

Opportunities

The greatest opportunity with Wild and Scenic Rivers is for protecting the free-flowing nature of the proposed rivers by legislatively preventing the construction of dams. Associated with the dam prevention would be increased opportunities for maintaining or improving: recreational uses; scenery, through guidelines on timber harvest and shoreline development; and wildlife, fisheries, soils, and water resources, both through guidelines on management activities as well as through the maintenance of the free-flowing nature.

18. Old Growth

There is currently an estimated 319,000 acres of old growth on the Wenatchee National Forest. This issue has taken on regional and national importance because of its relationship to the spotted owl. The major concerns are the impacts on timber harvest levels and the associated jobs, and the impacts on the population levels of the spotted owls. There are also concerns in preserving old growth for aesthetic reasons as well as ecosystem diversity. Another concern is that there will be no old growth left in the future.

Opportunities

There are opportunities to provide for preservation of old growth which would mean further protection for water quality, wildlife, native plants, and scenery and for leaving old growth for future generations. There are also opportunities for maintaining a maximum amount of acreage for old growth while reducing the impact on timber harvest levels.

IV. ANALYSIS OF THE ISSUES

Each of the individual Issues were analyzed to determine if they can be addressed as a group in the planning process. There were no opportunities to group issues. Most issues can be addressed in the planning process to at least some degree (Table A). The next step was how to best address the issues. Three methods are possible.

1. The issue is resolved through the management prescription or Forest-wide standards and guidelines.
2. The issue is indirectly resolved through the land allocations made in the design and goals of the alternatives.
3. The issue is directly resolved through specific land allocations in the design and goals of the alternatives.

The first method is appropriate for issues that do not involve land allocation or scheduling decisions or where there are no choices. All issues could to some extent be resolved by this method. In the second method the issue is resolved indirectly through the land allocations that are made. The issue indirectly affects the choice of land allocations in the alternative. The third method directly resolves the issue through the development of alternatives which provide choices about how much of the resource will be provided over time. In nearly all instances, the issues are resolved through a combination of method 1 with either 2 or 3.

TABLE A-1
PRIMARY DISTRIBUTION OF ISSUES FOR RESOLUTION

1. The issue is not directly resolved through land allocations in the design and goals of the alternatives. It is resolved through the management prescription and/or Forest-wide guidelines.
2. The issue is resolved indirectly through land allocation made in the design and goals of the alternatives.
3. The issue is resolved through specific land allocations in the design and goals of the alternatives.

PUBLIC ISSUES	MANAGEMENT CONCERNS	OPPORTUNITIES	1 GUIDE- LINES	2 ALTERNATIVES INDIRECTLY	3 ALTERNATIVES DIRECTLY
1 Recreational Opportunities & Use Conflicts	The management options and which ones to adopt.	Reduce conflicts through land allocations	x		x
2 Management of Areas That Are Presently Undevelopment	Future needs for various resources—recreation, timber wildlife habitat.	Provide for the projected needs based on suitability	x		x
3 Transportation System Development and Management	The Forest's ultimate road and trail system	Match the proposed transportation system with the management of the selected alternative goals	x	x	
4 Water Quality and Quantity	Special management direction needed to insure water quality	Enhance fish and wildlife habitat while providing other uses through management of riparian areas.	x		x
5 Mixed Ownership Management	Effects of intermingled ownership on National Forest resources	Consolidate National Forest ownership where necessary to meet resource objectives	x	x	
6 Wilderness	Overuse in key areas	Utilize education programs and public involvement in care and rehabilitation of wilderness	x		x
7. Wildlife and Fish	The location of key wildlife and fish habitat (winter range, spawning beds).	Locate and manage key wildlife-fish habitat specifically for wildlife and fish in cooperation with the Dept. of Wildlife.	x		x
8 Visual Resource Management	Level of management for the visual resource.	Complement other resource goal (wildlife habitat, water, timber, recreation) through V R M	x	x	x
9 Timber Management	The location of the commercial forest land and annual harvest level for the Forest	Allocate the most suitable and productive lands to timber management Exclude problem areas	x		x

TABLE A-1 (continued)
PRIMARY DISTRIBUTION OF ISSUES FOR RESOLUTION

PUBLIC ISSUES	MANAGEMENT CONCERNS	OPPORTUNITIES	1 GUIDE- LINES	2 ALTERNATIVES INDIRECTLY	3 ALTERNATIVES DIRECTLY
10 Energy	Future utility corridor needs.	Increase the capacity of existing corridors when possible and provide multiple uses of corridors.	x	x	
11 The Role of Fire	The influence that cost effectiveness has on protection levels.	Use prescribed fire to enhance resource values and provide protection from wildfire	x		x
12 Range Management	The present and projected demand for range forage	Manage livestock use to enhance the forage resource.	x		x
13 Minerals	Location and extent of mineral resources on the Forest.	Provide options for mineral exploration and development	x	x	
14 Cultural Resource	Loss or degradation of cultural resource	Locate, protect, and enhance cultural sites as part of the support of other activities	x	x	x
15. Cumulative Effects	Cumulative effects of timber harvesting, road building, and other activities on the environment	Reduce negative cumulative impacts through timber harvest scheduling and through coordination with other landowners, and buffer the effects of accelerated timber harvest on adjoining ownership, for example, by delaying harvest on National Forest system lands in sensitive watersheds	x	x	
16. Social and Economic Effects	Effects on program and budgets and local communities and governments	Provide the greatest net public benefits to local communities.	x	x	
17 Wild and Scenic Rivers	Effects on free-flowing rivers, timber harvest levels, and on private land-holders	Increase recreation opportunities, further protection for wildlife, fisheries, plants, soil, scenery and water	x		x
18 Old Growth	Location and amounts of old growth to protect, effects on timber harvest levels	Preserve old growth for wildlife dependent species, biological diversity, aesthetic values, and for future generations	x	x	x

V. REDUCING THE ISSUES TO PLANNING PROBLEMS

The analysis in the previous section, Part IV and Table A, identified how issues are to be addressed. To make this information more usable in the formulation of alternatives, the issues can be stated in the form of basic planning problems needing resolution in the Forest Plan. The planning problems are as follows:

PLANNING PROBLEM:

1. Are Forest lands capable and suitable of meeting public demand for particular types of recreation use? Where are these lands located?

Opinions are divided on the quantity and type of recreational facilities and opportunities the Forest should be providing. Some people want increased opportunities for unroaded non-motorized recreation outside of wilderness while others want increased opportunities for motorized recreation and developed sites. Opinions also differ regarding the use and restrictions of off-road vehicles (ORV's).

Some people are strongly opposed to ORV use in any way because of incompatibility with their recreation experience including noise pollution in narrow canyons such as Devil's Gulch, Lake Clara, and the Teanaway. Other people feel that relatively unlimited use of ORV's is acceptable. They also feel that the remaining unroaded areas outside of wilderness should be open to ORV use.

There is a demand to expand existing or construct new developed sites such as Mission Ridge and White Pass Ski Areas and developed campsites. On the other hand, there are those who prefer minimum development sites and the expansion of cross-country skiing opportunities. There is interest in designating specific land areas such as Lake Chelan, the North Fork of the Entiat, and Rock Creek for unroaded recreation with fewer restrictions than those applied to wilderness.

Conflicts between recreation and other Forest values were frequently mentioned. For example: the visual effects of clearcutting are generally considered to be incompatible with recreationists while others feel roads are important for providing recreation access. Concerns are expressed about soil erosion caused by site overuse or misuse. Management of the Pacific Crest National Scenic Trail and the need and potential for special classification areas such as Research Natural Areas, Scenic areas, and Botanical areas were also mentioned.

PLANNING PROBLEM:

2. What kinds of recreational opportunities should the Forest provide in non-wilderness roadless areas and how much of the roadless area should be allocated to commodity production?

Even after the addition of 340,795 roadless acres to wilderness through the Washington State Wilderness Act of 1984, the public is strongly divided on the future management of the remaining 556,272 acres of roadless areas. Some people would like to develop the maximum timber and other commodity potentials of these areas. Others would like these areas including the North Fork of the Entiat, Rock Creek, Devil's Gulch, Blue Slide, etc., to remain roadless and undeveloped.

Some prefer a balance between commodity use and roadless recreation based on suitability and multiple use. Wilderness proponents support the management of the roadless areas to maintain their potential for future additions to the Wilderness Preservation System.

The rate and level of development and the need for undeveloped recreation are parts of this problem. Some people are concerned about the effect of non-development on timber harvest levels and the levels of other resources such as range and minerals. There are also conflicts about what types of recreation opportunities should be provided in roadless areas (motorized or non-motorized).

PLANNING PROBLEM:

3. What rivers and streams should be recommended to Congress for inclusion into the Wild and Scenic Rivers system, and at what level of classification?

This planning problem was considered a part of planning problem #1 (suitability of lands for recreation use) in the DEIS, but due to public response to the Draft, the Wild and Scenic Rivers section was greatly expanded in the 1988 Supplement to the DEIS.

Some people believe that all of the rivers and many streams on the Forest should be included in a preliminary administrative recommendation to Congress for consideration under the Wild And Scenic Rivers Act. Other people are strongly opposed to the recommendation of some or all rivers and streams (or certain segments), particularly rivers or segments of rivers with private lands within the river corridor. Some are also concerned with the level of classification proposed for those river segments outside wilderness.

Issues and concerns associated with this planning problem include: recreation use and opportunity, amount of timber harvest, management of scenery, and the protection of most amenity values including wildlife, fisheries, plants, soils and water. A very important issue is the perceived threat to land owners concerned with condemnation, zoning and/or acquisition of easements on their land within the eligible river(s).

PLANNING PROBLEM:

4. How should water quality and quantity be maintained or enhanced?

The public is sensitive of the need to protect soil and water resources. Many people realize that improperly conducted management activities can cause damage to these resources. Logging, road construction, and off-road vehicle use were the focus of the public's concerns. It was frequently suggested that these activities be limited or modified to reduce their damaging effects.

Issues involved in the problem are: proper management in municipal supply watersheds such as Domerie Creek; reduction or elimination of water quality degradation; and management direction needed to maintain or enhance water quality and quantity.

Although water quality and quantity is of particular concern to people living in or near the Forest it is also of concern to people living many miles downstream. These people may be dependent on water for irrigation, such as those in the Wenatchee and Yakima valleys. Other people, including the Yakima Indians, are concerned about fish habitat and instream needs for fish migration.

PLANNING PROBLEM:

5. Where are the essential wildlife habitats, how should they be managed, and what direction should be taken to maintain or enhance wildlife diversity?

Some people believe that wildlife and fish management has not received appropriate attention within the Forest. Others believe there should be more emphasis on wildlife needs through coordinated timber or range management activities. Some people are very concerned about the effects of roads on wildlife. The future management of anadromous fish habitat and old-growth forest dependent species such as the northern spotted owl, pileated woodpecker, and marten is a major concern of another segment of the public.

Other public issues and management concerns related to this planning problem include the identification of essential habitats; the need for a road closure program to protect and enhance wildlife; wildlife and fish habitat needs; wildlife diversity; and fishery management including enhancement of flood-damaged streams.

Wildlife management requires close coordination with the Washington Department of Wildlife. Many comments expressed the need to better coordinate other Forest management activities with wildlife. Prescribed burning, timber harvest, including clearcutting and road construction, and road and trail management were identified as specific activities needing consideration. There are opportunities to use these tools to enhance wildlife habitat and hunting opportunities.

PLANNING PROBLEM:

6. How should Old Growth be treated? How much should be preserved and how much should be made available for timber harvest?

This planning problem was originally considered a part of planning problem #5 (essential wildlife habitats) in the DEIS, but due to public response to the Draft and Supplement, it was decided to make this a separate planning problem.

Some people believe that all existing old growth on the Forest should be preserved for biological diversity, dependent wildlife species, scenery or aesthetic values, and/or because they feel that no more old-growth forest will remain in a few years. Others believe that both existing and potential old growth within designated wilderness is more than enough to meet all future needs.

Public issues and concerns related to the planning problem include: natural biological diversity, timing of timber harvest and the amount of timber that can be harvested, protection of scenery, and management of old-growth dependent wildlife species.

Many respondents to the DEIS either grouped old growth with a list of amenity values that they felt needed more protection, or felt that protection of old growth would add further protection to water quality, wildlife, native plants (Threatened, Endangered and Sensitive species), and would preserve old growth for future generations.

PLANNING PROBLEM:

7. Where are the key or unique scenic resources on the Forest and how should they be managed?

Recreation visitors to the Forest are concerned about maintaining or enhancing the visual quality of the environment. Others would like to see the Forest managed for wood fiber with no or very few visual considerations. Some favor the maintenance of visual quality only in key travel corridors such as the I-90, Highway 2 and 97 corridors and the Pacific Crest National Scenic Trail. Others stress the multiple use benefits of maintaining scenery in combination with wildlife habitat, timber, water, recreation, and cultural resources. This segment of the public often favors maximum protection of scenic values.

Public issues and management concerns associated with this planning problem include: the effect of visual resource objectives on other resource uses, the effect of differing management philosophies on National Forest scenery resulting from the effect of intermingled landowners on National Forest scenery, and opportunities to maintain, restore, or enhance scenery.

Timber harvesting can be used to improve the scenery along travel routes and recreation areas. Timber harvesting can also be used to improve wildlife habitat and at the same time enhance scenery. There are opportunities to improve views or develop views of nearby features such as lakes, rivers, and mountains by opening vistas along travel routes.

PLANNING PROBLEM:

8. How much timber should be produced and where should it be produced?

Most people support timber management and harvesting on the Wenatchee National Forest. However, there is a concern about harvest location and logging practices used and their effects on other resources. Some people want increased emphasis on protection or preservation of scenery with little or no development. Others want increased wildlife habitat emphasis while management of commercial timber species, with full development of consumptive uses.

Public issues and concerns related to this planning problem address: the timing of timber harvest; the volume of timber that can be produced, the logging system and type of regeneration to be used; potential deviation from non-declining even flow; and the identification of the commercial forest land base (CFL). Availability of firewood is included in the problem.

Some people are concerned about the effects of timber harvest on water runoff and hydrologic balance. This concern is greatest where there are large percentages of intermingled private land, such as the I-90 and U.S. 2 Highway corridors and the Little Naches River watershed. There are opportunities to enhance visual quality, wildlife habitat, and recreation sites and areas by using various planned intensities of timber harvest. Timber harvest also provides opportunities for developing transitory range for livestock and providing wood for home heating and campers.

PLANNING PROBLEM:

9. What level of livestock grazing should the Forest provide?

Opinions differ on the use of public land for livestock grazing. Some feel that cattle and sheep cause *unacceptable damage to Forest resources and that commercial grazing is not a cost-effective use of the Forest's resources*. Others strongly favor grazing as a viable use of available forage and would expand this use. Timber harvest practices to increase available forage are favored by some.

Public issues and management concerns related to this planning problem referred to the proper level and intensity of grazing use considering range suitability. The competition between livestock and wildlife for forage is a related issue. Another related issue is water quality maintenance and the effect of grazing on the riparian-aquatic protection zone. There are opportunities to utilize livestock to control undesirable plant (brush and grass) competition in forest plantations and along trails.

PLANNING PROBLEM:

10. Where are the cultural resource sites on the Forest and how should they be managed?

The Native American community has strong concerns about the preservation of Native American cultural resource sites and use areas. There are also local community concerns about the protection and interpretation of cultural resource sites. There are 597 known and suspected cultural sites that have been identified on the Forest. Many of these are unique and provide the sole record of former habitats, ways of life, and past human activities.

Public issues and management concerns on this problem relate to finding and evaluating cultural resource sites prior to any site disturbing activities. A central concern is to provide a balance between other resource uses and the protection of individual cultural resource sites.

Impacts to cultural properties may be natural, project related, or the consequence of public use. The probability of loss of the cultural resource increases as lands are designated to uses involving land modifying activities such as timber harvest, road construction, range improvements and use, mineral exploration and development, and recreation development.

11. Other Planning Problems

There are a number of other issues that can be addressed primarily through the development of standards and guidelines. Six of these issues, #3, "Transportation System Development and Management;" #5, "Mixed Ownership Management;" #10, "Energy;" #11, "The Role of Fire;" #13, "Minerals;" and #15, "Cumulative Effects" are partially affected by land allocation decisions and therefore, must be considered in making these decisions. For instance, the issue "Management Direction for the Proposed Naches Pass Road" is included in Issue #3. Such a question would be resolved through the allocations in the alternatives which set the management direction for this area.

APPENDIX B

DESCRIPTION OF THE ANALYSIS PROCESS

I. INTRODUCTION

A. The General Planning Problem

The Forest Service is responsible for determining how to best manage National Forest System lands based on public desires and land capabilities. The Wenatchee National Forest is a highly diverse area with an equally diverse mix of users.

The Forest is located on the east slope of the Cascade Mountains in Central Washington. It stretches 140 miles from upper Lake Chelan on the north to the Yakima Indian Reservation on the south. It varies from 25 to 55 miles east to west, with 2,457,379 acres of land within its boundaries. Of this, 2,164,180 acres are National Forest System lands, the remainder are private, State or other Federal lands.

Vegetation varies from grass-shrub along the lower east side to subalpine parkland and alpine meadows along the crest of the Cascades. Ponderosa pine - Douglas-fir forest lands are found in the drier areas in between. True firs, hemlock, and western red cedar are predominant in the wetter areas. More than 790,000 acres were found to be tentatively suitable for timber production.

The Wenatchee's clear eastside weather and proximity to large population centers account for its recreational popularity. It is one of the most heavily visited National Forests in the Nation with almost four and one-half million recreation visitor days recorded in 1984.

Major east-west highways on the Forest include U.S. 12 - White Pass, I-90 - Snoqualmie Pass, and U.S. 2 - Stevens Pass. U.S. Highway 97 is a major north-south route that crosses Swauk Pass and then parallels the east side of the Forest from Wenatchee to Chelan. Much of the Forest is less than a three hour drive for the 2,290,000 people who live in the Puget Sound region.

Major sources of employment and income in the local area (Chelan, Yakima, and Kittitas Counties) are agriculture, service, and trade industries. Recreational use of the Forest and timber harvesting make important contributions to the local economy. Some of the smaller communities are particularly dependent on the Forest.

Public interest includes divergent viewpoints about the use of market commodities such as timber, grazing, energy, and nonmarket commodities such as wilderness, unroaded recreation, scenery, wildlife, old-growth, and habitat diversity. The Forest's major planning goal is to provide enough information to help decision makers determine which combination of goods, services, and land uses will maximize net public benefit. (This concept is further discussed in Section IV of this Appendix.) The National Forest Management Act (NFMA) and the regulations developed under NFMA (36 CFR 219) provide the analytical framework to address this objective, they also state that the requirements of the National Environmental Policy Act (NEPA) and its regulations (40 CFR 1500-1508) must be applied in this analysis process.

B. Changes Made Between Draft and Final

A new Alternative, Alternative J, was added in response to public comment. This Alternative was developed by timber industry representatives who referred to it in the public input as the "Essential Alternative."

In all Alternatives the Mature/Old Growth MR network was revised. The number of Spotted Owl Habitat Areas (SOHA's) was increased in response to the Supplement to the Regional Guide EIS. Management of the SOHA's changed from a "managed" to a "dedicated" prescription which now allows no timber harvest at all.

Alternatives A, C, E, F, G, H, and I all have different proposals for Wild and Scenic Rivers classification than shown in the DEIS. Alternatives C, E, and F have the new prescription MP-1 for the Mather Memorial Parkway on the Naches Ranger District.

Alternative C, the preferred, has numerous changes in allocation boundaries as well as the addition of two additional prescriptions: RE-4 Roadless Harvest, and EW-3 Roadless Wildlife.

A number of changes were also made in the modeling used for analysis of the alternatives:

- a. Growth was updated on existing timber yield tables to reflect new growth since the original yield tables were constructed. Acres that were cut-over since the original model was built were changed to reflect this in the FORPLAN runs for the final.
- b. The original FORPLAN model had a commercial thinning constraint that limited commercial thinning volume to 29 percent of the total volume for the first decade. After the first decade, commercial thinning volume could not vary by more than ± 50 percent from the previous decade. It was discovered that this constraint also applied to shelterwood entries. After examination of this constraint, it was discovered that there was no need to limit shelterwood entries, and that commercial thinning entries were a very small portion of first decade harvest. This constraint was, therefore, dropped from the model for the FEIS.
- c. The 1978 version of IMPLAN was used to predict changes in jobs and income. For the FEIS, the updated 1982 version of IMPLAN was used.
- d. Deer and elk winter range (EW-1) was originally managed under Special Prescription Yield Tables 2 and 3. These yield tables included managing the timber on a fairly long rotation. Since cover and early forage production were considered more important, Yield Table RM-1 was considered to be more appropriate for winter range in the FEIS.
- e. In the DEIS, the spotted owl, pine marten, three-toed woodpecker, and pileated woodpecker were managed using the same prescription and modeled with the same yield table. For the FEIS, a separate prescription was written for the spotted owl. The Spotted Owl Yield Table changed from managed old growth to dedicated old growth (no scheduled timber harvest). The prescription for the pine marten, three-toed and pileated woodpeckers was changed to one that produces the mature timber requirements for these species.

C. Planning Process

The planning and environmental analysis process brings a new outlook and a new technology to National Forest land management. Principally: (1) processes formerly used to make individual resource decisions are now combined to help make integrated resource management decisions; and (2) new mathematical modeling techniques are used to analyze alternative land management scenarios, including identifying the most cost-efficient pattern of land management. The 10-step planning process is discussed in the NFMA regulations and in Chapter I of this document. The steps are briefly summarized below:

Step 1: Identification of issues, concerns, and opportunities (ICO'S) - In any systematic approach to problem solving, the first step is to identify the problem. In this step, the Interdisciplinary Team (ID Team) identifies and evaluates public issues, management concerns, and resource use and development opportunities. *What does the public want? What does the Forest Service want? What needs to be done?*

Step 2: Planning Criteria - Criteria are designed to guide collection and use of inventory data and information, analysis of the management situation, and the design, formulation, and evaluation of alternatives. *This step sets the guidelines for accomplishing the next 5 steps.*

Step 3: Inventory data and information collection - The type of data and information needed is determined in step 2 based on the ICO's. The data is then collected and assembled in a manner meaningful for answering planning problems.

Step 4: Analysis of the management situation - This step is a determination of the ability of the planning area to supply goods and services in response to society's demands. This provides a basis for formulating a broad range of reasonable alternatives.

Step 5: Formulation of alternatives - A broad range of reasonable alternatives is formulated according to NEPA procedures. Alternatives are formulated in a manner which provides an adequate basis for identifying the one that comes nearest to maximizing net public benefits.

Step 6: Estimated effects of alternatives - The physical, biological, economic and social effects of implementing each alternative considered in detail are estimated and compared according to NEPA procedures.

Step 7: Evaluation of alternatives - Significant physical, biological, economic and social effects of implementing alternatives are evaluated with respect to the planning criteria.

Step 8: Preferred alternative recommendation - The Forest Supervisor reviews the Interdisciplinary Team's evaluation and recommends a preferred alternative to the Regional Forester. This is identified in the Draft Environmental Impact Statement and displayed as the proposed Plan.

Step 9: Plan approval - The Regional Forester reviews the proposed plan and Final Environmental Impact Statement and either approves, or disapproves, the Plan

Step 10: Monitoring and evaluation - The plan establishes a system of monitoring at established intervals to determine how well objectives have been met and how closely management standards and guidelines have been followed. Based on these evaluations, the plan will be revised or amended as necessary.

Appendix B describes the analysis phase of the planning process, covering steps 3, 4, 5, and 6. The judgment phase, steps 1, 2, 7, and 8, is described in Chapters I, II, and IV and in Appendix A. The execution phase, steps 9 and 10, is presented in the Forest Plan.

The following is the change in the process used to develop the No-Change Alternative:

Step 1: A public issue is a subject of widespread public interest identified through public involvement. Management concerns and opportunities are identified by the Forest Service. After issues, concerns, and opportunities are identified, the interdisciplinary team evaluates the responses and decides which ones will be considered. Current issues of widespread interest and existing management concerns and opportunities were not used in the development of Alternative NC.

Step 2: Planning Criteria - Planning criteria used to develop the No Change Alternative were not necessarily the same as those used to develop other alternatives. Alternative NC is based upon the 1963 Wenatchee Timber Management Plan and the 1969 Naches-Tieton Timber Management Plan. These plans predate important guiding legislation such as the National Environmental Policy Act of 1969, the Resources Planning Act of 1974, and the National Forest Management Act of 1976.

Step 3: Inventory Data and Information Collection - The No Change Alternative was based on resource inventory data available prior to 1977. Estimates of suitable acres for timber management were revised following passage of the Washington State Wilderness Act of 1984.

Step 4: The visual resource for Alternative NC used the concept of Landscape Management Units rather than the Visual Resource Management System that was used to define the visual resource for the rest of the alternatives.

Step 5: Formulation of Alternatives - Alternative NC, unlike other alternatives, does not necessarily use the most "cost effective methods of achieving resource objectives." It did not consider priced and non-priced outputs in the same analytical approach as the other alternatives. Alternative NC was developed by combining the existing direction in the multiple-use and unit plans with the timber outputs projected in the 1963 Wenatchee Working Circle Timber Management Plan and the 1969 Naches-Tieton Working Circle Timber Management Plan.

Step 6: Estimated Effects of Alternatives - The current Forest Service Planning models were not used to estimate the physical and economic effects of Alternative NC. Because of the lack of data it is not possible to use the current planning models to estimate environmental effects for Alternative NC beyond the first decade of the planning horizon.

II. INVENTORY DATA FOR INFORMATION COLLECTION

A summarization of the processes, events and actions occurring during planning step 3, Inventory Data and Information Collection, is outlined below. Inventory items and information used in this planning process are the most current and reliable available at this time. The primary objective was to use the best available sources. New field data was collected only if such information was specifically lacking in existing sources and the data was required to address issues.

A. Forest Data Base

Inventory data was assembled for many resources so that issues could be addressed, limitations defined, and capabilities determined. A portion of this data was necessary to develop the Forest Planning Model (FORPLAN) and to determine management and analysis areas.

The Wenatchee National Forest is using a computer mapping system known as Land Inventory Mapping (LIM). This system provides two alternative mapping methods. Each is available for use through the USDA's Fort Collins Computer Center, Fort Collins, Colorado. One of these, the Polygon Mapping System, has not been fully operational and is not used by this Forest. The second, the "GRID" Mapping system, has been used extensively by the Forest Service and has been adopted by the Wenatchee National Forest as the primary data storage and retrieval system for the Forest Plan. This system, known as R2MAP, uses basic information layers as initial input, then by overlaying two or more basic layers, other layers can be generated. Data summaries and/or maps can be created from either the primary or "generated" layers.

The LIM-R2MAP System setup for the Wenatchee National Forest uses a base map scale of 1 inch = 1 mile. Each grid is composed of a two digit code. Using the standard printer format of 10 characters per inch on each line and six lines per inch, each two character grid equals approximately 21 acres. Therefore, 21 acres is the smallest size area represented by R2MAP without changing the primary map scale of 1 inch = 1 mile. To change the R2MAP primary map scale would require reconstructing all inventory layers.

Once the basic inventory layers are available in R2MAP, numerous combinations of machine generated layers can be developed within a day or so. Complex overlays requiring more than one R2MAP run take proportionately longer.

R2MAP can provide site specific data from various inventories such as timber size classes, slope and soil data, ownership, political boundaries, watersheds, livestock allotments, developed campgrounds, recreation sites, critical big game winter range, and many other inventory and computer generated items.

Inventory data used to develop Alternative NC was different from that which was used to develop all other alternatives. Data collected prior to 1969 for the Naches area and 1963 for the rest of the Forest was used to develop the No Change Alternative. Data collected between 1977 and 1982 was used for the other plan alternatives. Significant differences exist in the amount and accuracy between data used to develop Alternative NC and what was used to develop other alternatives.

1. Delineation of Capability Areas

Capability areas are specific, contiguous areas of land which respond similarly to management practices in terms of certain outputs and effects. They are developed by overlaying maps of various physical, biological and administrative characteristics. Capability areas were originally mapped for the Forest with the intention of aggregating similar, noncontiguous ones together to form analysis areas. These analysis areas would then be used as the basic land stratification in FORPLAN.

The use of capability areas was found to be an inefficient and unnecessary step in the process, however. Given the type of computer mapping system available to the Forest, it was more efficient to go directly from the basic characteristics from which capability areas were developed to analysis areas. The mapping system and its application in analysis area development is explained in the following paragraphs.

Capability areas were not used to develop Alternative NC.

2 Stratification of the Forest into Analysis Areas

The Forest was stratified into analysis areas by overlaying various R2MAP layers. The specific analysis areas are described in Section III.C of this appendix. The inventory data used to build them are described below.

The first level of analysis area identifiers in FORPLAN specifies management status and roading status. Existing utility corridors, administrative sites, special use areas, cultural sites of known significance, arterial and collector roads, bodies of water over 21 acres, Tumwater Botanical Area, Entiat Experimental Forest, and Wilderness areas were mapped in various R2MAP layers. Roading status was derived from the Recreation Opportunity Spectrum (ROS) R2MAP Layer.

The next two levels of analysis area identifiers specify vegetative type and, for tentatively suitable timber lands, size class. This information was derived from R2MAP. The Vegetative Condition Class Layer was created in R2MAP to represent the Forest ecoclass condition, including timber size class. Tentatively suitable timber lands are also identified in the second level of analysis area identifiers. Timber suitability analysis is described in Section II.A.4 of this appendix.

It was noted during the construction process of this layer that the amount of mapping detail lost by using a 21 acre minimum size mapping unit appears to represent the original inventory detail within reasonable limits of error.

The original ecoclass inventory used as the foundation of this layer was guided, in part, by the following minimum photo mapping acreages for contrasting types on the Wenatchee National Forest (an extract from an attachment to Jorgenson's July 16, 1975, 1630/2410 memo "Stand Mapping and Classification," dated July 15, 1975):

- between nonforest or unproductive forest and commercial forest land - two acres,
- between ecoclasses in commercial forest land - five acres; in nonforest and unproductive forest - 10 acres,
- between maturity classes, size classes, or stocking within ecoclasses - 10 acres,

The forest-wide ecoclass mapping project done during 1976 and 1977 utilized black and white aerial photos taken just before the destructive wildfires that occurred during the summer of 1970. These photos were used to map all the Forest except the 1970 burn areas. A special flight of color aerial photos was taken shortly after the 1970 fires. These photos were used to map the ecoclasses within the burned areas.

This initial ecoclass mapping identified a considerable number of acres of tentatively suitable land as bare ground (denuded of trees). Most of these acres lie within the burned over areas.

The combined effect of intense wildfire and after-burn site deterioration from surface erosion has caused a number of acres to change from a "tentatively suitable" condition to a "non-forest" or "unsuitable" condition. Also, the intensity of the wildfires was so great that the normal aids to photo identification of tentatively suitable lands (stumps, logs, and snags) are missing or not visible on the color aerial photography. Because of this, the potential for incorrectly classifying the severely burned areas was increased considerably. Early reforestation survey activities within the burned over areas indicated a need to remap the ecoclass potential of the burns.

Most of these burned areas are on the Chelan Ranger District. A District field survey of the burned-over areas was initiated in 1978 and continued through 1983. This survey provided new ecoclass designations which provided the basis for revising that portion of the Forest-wide ecoclass mapping project within the burned over areas. These revisions are included in the Vegetative Condition Class Layer in R2MAP.

The basis for this layer was the Total Resource Inventory (TRI) Ecoclass Subsystem. TRI is a System 2000 (S2K) computer database used to store site specific resource data.

The TRI Ecoclass Subsystem had to be updated from the photo mapping base of 1970. This was necessary to more accurately represent the actual conditions of timber removal or timber stand modification resulting from commercial timber sales since 1970.

All timber sale activity from 1970 through January 1, 1989, was included in the revised inventory base map used to update the Vegetative Condition Class Layer. The cutoff date of January 1, 1989, represents the most current inventory of harvest activity for this planning effort.

The Wenatchee developed a biological model for timber planning purposes early in 1976. A group consisting of the Forest Silviculturists, Timber Management Planner, and other timber management personnel developed the model with consultation and guidance from Allan Lampi, John Teply, Dave Bernstein and Carl Puuri of the Regional Office. Since its development, we have re-evaluated the model several times and feel confident in its applicability.

The foundation of the model is the stand and ecoclass mapping done during 1974 and 1975 under supervision of Tom Beebe, Silviculturist, with the guidance of Dave Bernstein, R.O Timber Planning and Photo Interpretation Specialist. This mapping process utilized the stand classification system, as developed by Dave Bernstein, entitled Stand Mapping and Classification, C.G. Jorgensen, 1630 (2410) memo dated July 16, 1975, and the ecoclass identification system, developed by Fred Hall, entitled Pacific Northwest Ecoclass Identification, USDA-FS-R6 Regional Guide 1-1 and Codes for Pacific Northwest Ecoclass Identification, USDA-FS-R6 Regional Guide 1-2. Both of these publications are dated January 1974. Also included in the mapping process was a study of methods to determine site productivity, so as to be better able to separate productive from non-productive forest land. Oral advice and written information on this subject were received from Fred Hall, Colin Maclean, and Charles Bolsinger, Pacific Northwest Experiment Station, Portland, Oregon. A further refinement of the mapped mature stands was done by Bob Pederson in 1977. It was determined that the mature stands as mapped were too broadly stratified. Under the advice of Al Lampi and John Teply, these stands were further delineated to break out areas containing photo identifiable immature seedlings and saplings, poles and small sawlogs under mature overstory. Immature understory had to meet minimum density levels considered to be fully stocked in order to qualify. Two storied stands with understocked immature trees were classified with mature stands without understory. Documentation of the stand mapping procedure and codes used is available at the Forest Supervisor's Office in Wenatchee.

Stand productivity was modeled by grouping ecoclasses of broadly similar capability. This method was decided upon because it is the best existing mapped data available. The preliminary model had three groupings:

I. Dry sites represented by CP and CD ecoclasses.

II. Moist, more productive sites represented by CE, CF, CH, CW and CS ecoclasses.

III. A group containing CL and CM found at higher elevations.

Legend:^{1/}

“C” - Conifer Climax Plant Community

“P” - Ponderosa Pine Major Climax Species

“D” - Douglas-Fir Major Climax Species

“E” - Alpine Fir/Englemann Spruce Closed Forest Major Climax Species

“F” - Silver or Noble Fir Major Climax Species

“H” - Western Hemlock Major Climax Species

“S” - Spruce Major Climax Species

“L” - Lodgepole Pine Major Climax Species

“M” - Mountain Hemlock Major Climax Species

^{1/} From “Ecoclass Coding System for Pacific Northwest Plant Associations, USDA FS, PNR, R6 ECOL 173-1984, January 1984.

Group III was subsequently combined with group II because of a very small acreage (approximately 5,000 acres) and because only one inventory plot is located within the group. The 1977 timber inventory plot layout used the previous Forest-as-a-whole sample plot locations. A description of the process used follows:

The 1977 timber management inventory utilized the Field Instructions for Timber Management Inventories Region 6, U.S.D.A., Forest Service, Portland, Oregon, 1976. On the Wenatchee National Forest the field sample consists of field plots located on a systematic grid 1.7 miles square. The inventory grid does not cover reserved forest lands. Reserved includes forest lands withdrawn from timber utilization by statute, administrative regulation (Code of Federal Regulations), or by designation in land use plans approved by the Regional Forester.

The field plot consists of 10 sample points distributed over approximately one acre and located at the apexes of equilateral triangles with 70 foot sides. At each of these points data are collected on the species, size, and quality characteristics of the trees present. If no trees are present at a point, a record is made of the ground conditions which influence current or prospective stocking.

Dispersion of the 10 sample points over the sample acre permits calculating not only the total or average stocking or other condition for the sample acre, but permits evaluation of the variation within the acre. This makes it possible to evaluate how effectively the trees present are using the available growing space.

At each field plot location, the land is first classified as commercial forest, noncommercial forest, or nonforest. If the land is commercial forest, a field plot is established; if not, no plot is taken.

A variable radius plot is taken at each of the 10 points. Trees 5.0 inches d.b.h. and larger are tallied.

A 1/300-acre fixed radius plot is established at each of the 10 points. Trees 1.0 inch d.b.h. to 4.9 inches d.b.h. are tallied.

A tally is made of all established seedlings (under 1.0 inch d.b.h.).

On sample points 1, 2, 3, extra data are taken to provide information on rates of growth and mortality. On these points diameter is recorded to the last 0.1 inch for all trees 1.0 inch d.b.h. and larger, and trees over 5.0 inches d.b.h. are bored to obtain growth data.

The last level of analysis area identifiers specifies slope and soil hazard. These factors were derived from Soil Resource Inventory (SRI) data which was mapped into R2MAP.

This layer was constructed from two Forest Soil Resource Inventory (SRI) mapping projects:

- The Naches/Tieton portion of the Mt. Baker-Snoqualmie Eastside SRI project was completed April 15, 1973. Field mapping was conducted from July through October 1970 by Soil Scientists Robert V. Snyder, John M. Wade, and Raymond Lavine.

- The Wenatchee SRI project was completed in 1976. Field mapping was conducted from April 1972 to October 1975 by Phillip D. McColley.

The Wenatchee National Forest's Soil Scientist, Phillip McColley, provided the expertise to assemble the soil codes from both of the above SRI's into groupings of similar soil types and to edge-match soil types along adjacent boundaries.

Analysis areas were not used to develop Alternative NC.

3. Determination of Production Coefficients

The processes used to develop production coefficients are described in Section III.F of this appendix. Data used in these processes are summarized below.

<u>R2MAP Layer</u>	<u>Activity/Output</u>
Vegetative Condition Class	timber livestock forage wildlife forage water sediment old-growth
Soil Resource Inventory	livestock forage wildlife forage sediment logging costs road construction
Recreation Opportunity Spectrum	dispersed recreation sediment

(See section 7B of this Appendix for sources of the data.)

4. Determination of Suitability for Management Practices

The suitability of specific areas of the Forest for various management practices was examined at several levels. When management prescriptions were developed, the types of areas to which they were applicable was specified. FORPLAN prescriptions were also screened to determine which analysis areas were appropriate. For example, a range management prescription emphasizing vegetative manipulation is inappropriate for non-vegetated analysis areas.

The NFMA Regulations require the identification of lands which are not suited for timber production (36 CFR 219.14). A three stage screening process is employed. The last two stages are determinations of economic efficiency and interactions with other resource objectives. The first stage is a determination of tentative suitability. Lands are eliminated based on four criteria. These are outlined below, along with the specific factors used to identify them on the Wenatchee National Forest:

a. The land is not Forest land.

This criteria was met through the use of the Forest timber inventory conducted in 1977.

b. Technology is not available to ensure timber production from the land without irreversible resource damage to soils productivity or watershed conditions.

Avalanche Paths:

-Areas that have a series of avalanche chutes which occupy more than 50 percent of the area.

Mass Failure Areas (Rotational Slump/Earth Flows):

-Areas where there is a well defined escarpment at the uppermost elevation where the slide mass has pulled away from the slope.

-Areas where the surface of the slide is irregular and undulating. Wet areas, springs, and ponds are also characteristic of this landform.

-Areas where the slide possesses a readily recognizable "toe" or "snout," rounded in form, and coming in contact with the underlying surface at a sharp break in the slope.

-Areas where the slide has not come to rest as defined by its position on the slope.

-Areas where management activities can be expected to increase the risk factor (WRENS) by two.

-Areas which are 20 acres or more in size.

Debris Flow:

-Areas which, when viewed stereoscopically, indicate slopes of 60 percent or greater adjacent to the stream channel.

-In association with the above criteria, areas where 40 percent or more of the area have active or previously active slides.

-Areas which are 20 acres or more in size.

c. There is no reasonable assurance that such lands can be adequately restocked within 5 years after final harvest.

Rocky Soils:

-Areas where the rock content of the soils exceeds the limits suggested by Boyer.

Droughty Soils:

- Areas of droughty soils with low field capacity or other indicators of moisture availability.

This criteria will apply only to dry forest and low productivity areas. It applies to soils where the available water holding capacity of the upper 18 inches of soil is 2.5 inches or less.

Wet Areas:

- Areas of wet soils and/or high water table.

Serpentine Soils:

- Areas where serpentine soils are found in over 45 percent of the area.

High Elevation:

- Areas above the 6,000 foot elevation.

Excessive Slopes:

- Areas having slopes greater than 10 percent.

Regeneration Problem Areas:

-Areas of "open park-like" subalpine larch, subalpine fir, and white bark pine mapped as unproductive CA type.

-All areas mapped as unproductive dry ecotypes "CD/U" and/or "CP/U".

-Dry types above 5,000 feet in elevation on slopes over 40 percent facing south, southwest, and west.

-Sites mapped as marginal due to regeneration difficulty in original ecotype mapping.

-Swampy soil and wetlands.

-All ecotypes above 6,000 feet.

-All mountain hemlock dominated ecotypes (not those with a minor component of mountain hemlock).

-Slopes over 99 percent.

- d. The land has been withdrawn from timber production by an Act of Congress, the Secretary of Agriculture or the Chief of the Forest Service.

This criteria was met by the delineation of the applicable lands.

The characteristics identified above were mapped into several different R2MAP layers. Lands which met the above criteria and the remaining lands which were tentatively suitable for timber production were identified by overlaying these layers. The results of this analysis are summarized in Table B-II-1.

The No Change Alternative was based on a different concept of suitability for timber management than the other alternatives. For Alternative NC, commercial forest land (land considered suitable for timber management) included all lands capable of producing crops of wood with growth in excess of 20 cubic feet per acre per year that were not withdrawn from timber production by statute or by administrative regulation. Biological criteria for regeneration of trees following harvesting, and consideration for avoiding irreversible or irretrievable damage, were not included in the definition of Commercial Forest Land used to develop Alternative NC.

TABLE B-II-1
LAND TENTATIVELY SUITABLE FOR TIMBER PRODUCTION

	Not Suited For Timber Production	Totals
I Total National Forest Area		2,457,379
Other Ownerships		293,199
II. Net National Forest		2,164,180
A Water	11,024	
B Non-Forest (not stocked with 10 percent tree cover)	666,828	
C. Lands developed for other than timber production purposes*		
Ski areas, developed recreation, administrative areas, improved roads, special uses.	35,230	
III Forested Lands		1,451,098
A.. 1. Wilderness	430,788	
2. Research Natural Areas	1,038	
3 Other such as:		
Tumwater Botanical Area	784	
Entiat Experimental Forest	<u>4,219</u>	
Subtotal	436,829	
B. Lands growing less than 20 cu ft./ac./yr.		
1. Lands classified as unsuitable	137,717	
2. Lands classified as suitable		(6,148)
3. Lands classified as separate suitability component	0	
C. Irreversible resource damage (219.14(a)(2))	18,720	
D. Regeneration Difficulty (Reforestation cannot be guaranteed) (219.14(a)(2))	65,933	
E. Regeneration difficulty (lands classified as a separate suitability component)	0	
IV Tentatively suitable Forest Land		791,899
	<u>Total Non-Suitable</u>	<u>Total Tentatively Suitable</u>
V. Totals of Suitable and Non-Suitable Lands	1,372,281 ^{1/}	791,899 ^{1/}
VI Land Status under Current Timber Management Plan Revised/Approved 10/19/84	<u>Timber Component</u>	<u>Acres</u>
	Standard	682,251
	Special	<u>105,500</u>
	Subtotal	787,751

^{1/} Includes Alpine Lakes Management Area Non-harvest land allocations

The second stage of the timber suitability analysis involves examining the present net value of all timber harvesting options on a per acre basis. Present net value was calculated for each analysis area/management prescription/timing option combination using only timber benefits and costs. The options for each analysis area were ranked in order of decreasing present net value. Examination of this information provided insights into which prescriptions were likely to be selected in FORPLAN runs with an objective of present net value maximization. Options which had negative present net values were noted.

GF-4, the General Forest Management Prescription involving clearcutting and planting with no precommercial or commercial thinnings, had the highest PNV in most cases. GF-3 and GF-1, more intensive versions of the General Forest Management Prescription, often had only slightly lower present net values. On seedling/sapling analysis areas, GF-4 and GF-6 were the only options with positive PNV's. Bare ground analysis areas had no positive PNV's.

5. Development of Allocations and Scheduling Alternatives

The Forest was stratified into analysis areas as described in Sections II.A.2 and III.C of this appendix. Management prescriptions were developed as described in Section III.D. Timing options and yield coefficients are described in Sections III.E and III.F, respectively. The application of different management prescriptions to analysis areas, with varying schedules of activities and outputs, defined the alternatives. The analysis process is detailed in Section III.B and alternative development is discussed in Section III.

6. Monitoring of Implementation

A Monitoring Plan is included as Chapter VI of the Forest Plan. It addresses monitoring of specific management prescription allocations and their associated practices to determine if they are causing a significant deviation from the predicted outputs, effects, and costs, and if standards, guidelines, and activity statements have been met.

7. Development of Subsequent Programs for Plan Implementation

Much of the data used to develop alternatives can be used to prepare programs and projects for implementing the plan. Some projects may need a higher degree of resolution than the 21 acre minimum size of much of the Forest planning data, however. Other inventory data is available for project purposes, particularly in the Total Resource Inventory (TRI) system.

B. Sources of Existing Data

The Wenatchee National Forest used or considered the following sources of data during the analysis process:

Recreation Information Management System (RIM)

This locally collected data provides recreation facility, site inventory and maintenance data as well as recreation activity use statistics. It also contains field estimates of hunting, fishing, and non-game wildlife use.

Visual Quality Objectives (VQO)

This R2MAP data shows inventoried visual resource data used for depicting the current situation June, 1980.

Existing Visual Condition (EVC)

This map shows the present state of visual alteration of the landscape measured in degrees of deviation from the natural appearing landscape (map overlay 2"/mile, used in conjunction with existing ROS classes). 1984

Visual Absorption Capacity (VAC)

This map overlay shows the relative ability of the landscape to absorb management manipulations without significantly affecting its visual character. 1980.

It was developed to provide data to rate viewsheds ability for long-term visual condition.

Viewsheds

Delineation of the Forest's 34 viewsheds was done to give more specificity of visual resource information for tracking how these changed in the alternatives (R2MAP). September, 1984.

Wildlife Habitats in Managed Forest's, the Blue Mountains of Oregon and Washington USDA Handbook No. 553. USDA, 1979

This report contains data on species distribution, use of forested habitats, and the influence of forest management on wildlife.

Wildlife of the Pacific Northwest: Occurrence and Distribution by Habitat, BLM District, and National Forest.

Guenther, Keith and Thomas E. Kucera, USDA, 1978.

This report features a table format that displays wildlife species occurrence in the Northwest

Inventory data used to develop Alternative NC differ greatly from data used to develop other alternatives.

Timber volume outputs for Alternative NC were based upon data collected in the 1961 inventory for the Wenatchee Working Circle and 1968 timber inventory for the Naches area. Management areas identified in District Multiple Use Plans were also used.

Strategies For Washington Wildlife

Washington Department of Game, 1982.

This report contains a comprehensive framework for the management of Washington wildlife and game fish resources until 1995. It sets statewide goals and objectives.

Big Game Status Reports, 1980-1981-1982.

Washington Department of Game, 1983.

Populations and harvest by management units are displayed.

Management Strategies for Region 3 Wildlife (Draft)

Washington Department of Game

This report establishes specific goals and objectives for herd units or management units.

Non-Game Data Base

Washington Department of Game, 1985

A computer printout of threatened, endangered, and sensitive species locations was obtained from this data base.

Threatened, Endangered, and Sensitive Plants.

Washington Natural Heritage Program, 1985.

This printout lists locations and sighting information for threatened, endangered, and sensitive species.

Maps of Anadromous and Resident Fish Distribution on the Wenatchee National Forest, by Ranger District

This map was prepared by Districts with coordination from Steve Kessler.

Estimated "existing," "current potential," and "potential with enhancement" fish production data for streams and lakes on the Wenatchee National Forest

Wischnofske, Merle (updated by Steve Kessler)

Information from this report was also updated based on input from the Washington Department of Fisheries, Washington Department of Game, Yakima Indian Nation and U.S. Fish and Wildlife Service.

-Plant Communities of the Blue Mountains in Eastern Oregon and Southeastern Washington

Hall, Frederick C., 1973

This publication describes plant communities in portions of Oregon and Washington, and includes production of forage within the communities.

Forested Plant Associations of the Okanogan National Forest

Williams, Clinton K. and Terry R. Lillybridge, 1983

This publication describes plant associations on the Okanogan National Forest and the amount of forage produced within these associations.

Coefficient Development for Forage Production

McCutchen, Edwin L., 1981

In a memo to the 1920 Land and Resource Management Planning files, the author describes a process used to develop Forage Production Coefficients for use with Version I FORPLAN for the Wenatchee National Forest.

Soil Survey of Chelan Area, Washington, Parts of Chelan and Kittitas Counties

USDA, Soil Conservation Service in cooperation with Washington Agricultural Experimental Station, 1969

This publication is a soil survey of lands within and adjacent to the Wenatchee National Forest and contains forage production on certain vegetative types in the lower elevations of the Forest.

Overstory - Understory Relationships in Western Forests

Western Regional Research Publication No. 1

This publication describes certain vegetative relationships resulting from timber harvest on National Forests in the West. Types of overstory and understory vegetation including the amount of forage produced depending on percent of overstory removed is discussed.

Total Resource Inventory (TRI)

This is a regional system for storing data on current stand conditions and activities planned or accomplished in those stands.

1977 Wenatchee Forest Inventory

This inventory provided data on tree volume, species, growth, age classes, and stand sizes. This information is the basis for the Forest's existing timber yield tables.

1984 Reforestation and Timber Stand Improvement Report

This report gives the amount of needed, proposed, and accomplished reforestation and timber stand improvement. It has also been used to annually track the progress of backlog reforestation.

1985 Timber Yield Table Documentation

Managed timber yield tables were based on Prognosis model variant 640 version 4.2 developed by Wykoff, Croohston and Stage.

Empirical Yield Tables for the Wenatchee

These were prepared by John Teply, Region 6 Biometrician, from 1977 timber inventory data.

Local Mill Capacities

Developed by telephone survey conducted by Timber Staff Officer Fred Walk in 1985.

An Approach to Water Resources Evaluation of Non-Point Silvicultural Sources (pp. 49-63).

E.P.A. - 600/8 - 80 - 012, August, 1980

This process was used in conjunction with the Warrington procedure, for estimating soil erosion for forest land management planning.

A Perspective on the Cumulative Effects of Logging on Streamflow and Sedimentation

Rice, Raymond M., Research Hydrologist, Pacific Southwest Forest and Range Experiment Station, Forest Service, USDA, Berkeley, Calif., 1980

This paper discusses strategies for mitigating cumulative effects. It also describes the synchronized effects and some of the causes of the problem.

A Watershed's Response to Logging and Roads

Rice, Raymond M., Forest B. Tilley, and Patricia A. Datzman, Pacific Southwest Forest and Range Experiment Station, Forest Service, USDA, Berkeley, Calif. 1979

This paper discusses the mechanics of soil movement and talks about soil loss and water quality. The focus is on road construction and selective timber harvest in watersheds.

Are Forest Residues Needed Assets for Soil Protection and Maintaining Future Site Productivity?

Klock, G.O., Research Soil Scientist, Pacific Northwest Forest and Range Experiment Station, Forest Service, USDA, Wenatchee, Wa.

This paper discusses the importance of maintaining some forest residues in place, nonwettability conditions, and other factors that may affect soil productivity.

Designing Skid Trail Systems to Reduce Soil Impacts from Tractor Logging Machines

Froehlich, H.A., Professor, Forest Engineering, OSU; D.E. Aulerich, President, Forest Engineering Incorporated, Corvallis, Ore; and R. Curtis, Forest Engineer, Land Management Services, Springfield, Ore., 1981

Effects of Logging and Logging Roads on Erosion and Sediment Deposition from Steep Terrain

Megahan, W.F., Forest Hydrologist, Intermountain Forest and Range Experiment Station, Forest Service, USDA, Ogden, Utah; and W.J.Kidd, N.E.Area, State and Private Forestry, Columbus, Ohio., 1972

This paper compares different ground disturbance activities associated with logging (skyline, jammer, and road construction).

Effects of Fire on the Long-Term Maintenance of Forest Productivity

Klock, G.O., Research Soil Scientist, Pacific Northwest Forest and Range Experiment Station, Forest Service, USDA, Wenatchee, Wa.; and C. C. Grier, College of Forestry, University of Washington, Seattle, Wa.

This paper discusses the effects that fire can have on the soil resource.

Erosion over Time on Severely Disturbed Granitic Soils: A Model, USDA, Forest Service Research Paper, INT - 156

Megahan, W.F., Forest Hydrologist, Intermountain Forest and Range Experiment Station, Forest Service, USDA, Ogden, Utah., 1974

This process was used in conjunction with the Warrington process for determination of the delivered sediment index values.

Erosion Processes and Control Methods in North America

Swanston, Douglas N., Principal Geologist, Pacific Northwest Forest and Range Experiment Station, Forest Service, USDA, Corvallis, Ore., 1978

This paper describes the different kinds of erosional processes that affect forested lands. It also discusses methods of controlling erosion.

Estimating Soil Erosion on Forest Land Management Planning: A Procedure: In Forest Soils and Land Use

Warrington, G.E., Soil Scientist, Forest Service, USDA, Fort Collins, Colo., 1978

This publication describes the process used for the determination of delivered sediment index values.

Logging, Erosion, Sedimentation - Are They Dirty Words?

Megahan, Walter F., Research Hydrologist, Intermountain Forest and Range Experiment Station, Forest Service, USDA, Ogden, Utah., 1972

This paper discusses the effect of road construction on the total amount of sediment produced.

Predicting Soil Compaction on Forested Land

Froehlich, Henry A., Professor, Forest Engineering; J. Azevedo, Research Assistant, Peter Cafferata, Graduate Research Assistant; and Dave Lysne, Graduate Research Assistant, Oregon State University, Corvallis, Ore., 1980

This publication discusses the mechanics of soil compaction, duration of effect, and tests for the determination of soil compaction.

Slope Stability Problems Associated With Timber Harvesting in Mountainous Regions of the Western States.

Swanston, D. N., Principal Geologist, Pacific Northwest Forest and Range Experiment Station, Forest Service, USDA, Portland, Ore., 1974

This publication discusses the classification of mass failures, and the interrelationships between principal factors that produce landslides on timbered slopes. It also covers the effect of different forest operations and some methods to use to predict, prevent, and control landslides.

Soil Monitoring Project Report on Payette National Forest and Boise Cascade Lands

Froehlich, Henry A., Professor, Forest Engineering Dept.; D.W.R. Miles, Research Assistant; R.W. Robbins, Graduate Research Assistant; and J.K. Lyons, Former Research Assistant, Oregon State University, Corvallis, Ore., 1983

This paper discusses the cumulative effect of repeated trips over a soil, and the duration of the compacted layers in several different textured soils.

Soil Resource Inventory (SRI), Wenatchee National Forest

McColley, Phillip D., Soil Scientist, Wenatchee National Forest, USDA, 1976

This publication presents broad soil information, identifies physiographic land types, and gives soil interpretations for planning purposes based on probable hazards or suitability for management.

Soil Resource Inventory (SRI), Snoqualmie National Forest - Eastside

Snyder Robert V., and John M. Wade, Soil Scientists, Snoqualmie National Forest, USDA, Seattle, Wa., 1973

This publication presents broad soil information, identifies physiographic land types, and gives soil interpretations for planning purposes based on probable hazards or suitability for management.

Soil, Vegetation and Watershed Management of the Douglas-Fir Region

Fredricksen, R.L., Research Soil Scientist, and R.D. Harr, Research Hydrologist, Pacific Northwest Forest and Range Experiment Station, Forest Service, USDA, Corvallis, Ore.

This publication describes the processes of mass failure and surface erosion processes in the forest environment.

Some Soil Erosion Effects on Forest Soil Productivity

Klock, G.O., Research Soil Scientist, Pacific Northwest Forest and Range Experiment Station, Forest Service, USDA, Wenatchee, Wa., 1982

This publication discusses the effects of soil erosion on nutrient availability, as well as the importance of maintaining the organic matter content in forest soils. It also discusses the location of most of the available plant nutrients in forested soils.

The Influence of Soil Compaction on Young Tree Growth on the Yakima Indian Reservation

Froehlich, Henry A., Professor, Forest Engineering, and Richard W. Robbins, Graduate Research Assistant, Oregon State University, Corvallis, Ore., 1983

This publication discusses changes in soil bulk density associated with logging. It also talks about the effect of soil displacement and the removal of the nutrient-rich surface soil during logging and slash disposal.

Water-Repellent Soils: Their Implications in Forestry

DeBano, L.F., Research Soil Scientist, and R.M. Rice, Research Hydrologist, Pacific Southwest Forest and Range Experiment Station, Forest Service, USDA, Berkeley, Calif.

This paper discusses the effect on increased runoff and soil erosion resulting from fire caused water-repellent soils.

U.S. Bureau of Mines Mineral Industry Location System (MILS)

U.S. Bureau of Mines, 1980

This is an inventory system which provides location and related information on metallic or non-metallic mineral occurrences, prospects, mines, geothermal wells, and on mineral processing plants

Availability of Federal Land for Mineral Exploration and Development in the State of Washington

Banister, D'Arcy, Donald J. Barnes, Warren D. Lungwill, State of Washington, Department of Natural Resources, Division of Geology and Earth Resources, 1984.

This reference provides maps depicting: (1) the availability of public lands for mineral exploration and development; and (2) the significant known metallic deposits with their associated geologic Terranes and areas underlain by reported coal deposits.

Inventory of Washington Minerals, Part I and Part II

Hutting, Marshall T., State of Washington Department of Conservation and Development Division of Mines and Geology Bulletin No. 36, 1956.

This publication provides a brief annotated list of all the metallic mineral occurrences in Washington known to the Division of Mines and Geology.

Mineral Resource Analysis Study on United States Forest Service Land, State of Washington

Grant, Alan Roberts, 1976

This provides a review of short and long range mineral potential on Forest Service lands in the State of Washington.

Map of the Economic Mineral Potential Areas, Wenatchee National Forest
Meschter, Daniel Y., Mining Engineer, 1983

This inventory provides broad mineral resource information and indicates, on a Forest-wide basis, the probability of mineral resource occurrences and their relative potential for development.

Map of Areas of Critical Mineral Potential, 1st Edition
Bee, S., 1983

The map indicates, on a scale of 1:500,000, those areas nominated as areas of "critical mineral potential" in a Bureau of Land Management nomination process.

U.S. Geological Survey Leasable Mineral Classification Maps
Lands Valuable for Geothermal Resources, Oct. 1979
Lands Valuable for Oil and Gas, Aug. 1979
Lands Valuable for Coal, February 1983.

Lands Valuable for Sodium and Potassium, February 1978

These maps show, on a scale of 1:500,000, those lands that are classified as being "prospectively valuable" for oil and gas, "prospectively valuable" for geothermal or are "known geothermal resource areas", "prospectively valuable" for coal or as a "coal" area and as being "prospectively valuable" for sodium and potassium resources.

Wilderness Mineral Potential Assessment of Mineral Resource Potential in U.S. Forest Service Lands Studied 1964-1884
U.S. Geological Survey, Professional Paper 1300, 1984

This report provides a summary of the mineral resource assessment completed on a number of the wilderness, primitive and roadless areas within the Wenatchee National Forest.

Mineral Resource Potential Map of the Glacier Peak Wilderness and Adjacent Areas, Chelan, Skagit and Snohomish Counties, Washington

Church and others, U.S. Geological Survey Miscellaneous Field Studies Map MF-1652-A, 1984)

This report provides a summary of the mineral resource evaluation of the subject area. The report includes a map (scale of 1:100,000) depicting the mineral resource potential of the area and a narrative summarizing the result of the evaluation.

Mineral Resources of the Cougar Lakes - Mount Aix Study Area, Yakima and Lewis Counties, Washington

Simmons, George C., Ronald M. Van Noy and Nicholas T. Zilka, U.S. Geological Survey Open-file Report 74-243, 1974.

This report provides a mineral resource evaluation of the subject area.

Mining Claim Recordation Index

Bureau of Land Management, May 10, 1985 (latest index)

This index provides an inventory of all mining claims located on the Wenatchee National Forest which have been recorded with the BLM as is required by law.

Economic Analysis Revision of November 10, 1983 Regional Direction Package
USDA, Region 6, April 27, 1984.

This direction package specifies benefit values, base year dollars and conversion factors, and a methodology for reflecting price-diameter relationships for timber values.

The Derivation of Cut Stumpage Values from the Timber Sale Statement of Accounts Data-Base for National Forests in Region 6 and Cut Stumpage Values provided by Hays and Barranco
Hays, James F. and Gary Barranco, unpublished manuscript, Rogue River National Forest, March 15, 1984.

These stumpage values by species were the basis of the timber values used in FORPLAN.

FORPLAN Harvest Costs

These were the basis of the logging costs used in FORPLAN. They were estimated by John Malone and Charlie Stansel, Wenatchee National Forest, by making hypothetical timber sale appraisals.

Wenatchee National Forest Cost Estimates

These are estimates of Forest Service costs by MIH code. They were estimated by Forest specialists for each resource and reviewed by the responsible staff officers. These costs were used in budget estimation and economic efficiency analysis.

1961 Timber Inventory Data for the Wenatchee Working Circle.

1968 Timber Inventory Data for the Naches-Tieton Working Circle.

The above documents are on file at the Wenatchee National Forest Supervisor's Office.

III. THE FOREST PLANNING MODEL

A. Overview

Forest Planning is a very complex process in which an enormous amount of information and interdependent decisions must be considered before an alternative management plan can be recommended as the one which best addresses the issues, concerns, and opportunities that were identified at the outset of the planning problem. Because of this, several interrelated computer models and analytical tools have been developed and utilized to help determine the decision space within which alternatives can be developed and to evaluate their associated outputs and effects. These tools are also helpful in determining the most efficient means of meeting the goals and objectives of alternatives.

The major model used is called FORPLAN, an acronym for FOREst PLANning model. FORPLAN is a linear programming based computer modeling system. It has its roots in earlier systems such as RAM (Resource Allocation Model) and MUSYC, (Multiple-Use Sustained Yield Calculations); however, it is much broader in scope. FORPLAN consists of three components:

- 1) a matrix generator to translate the Interdisciplinary Team's input into the proper format for the linear programming component to use,
- 2) a linear programming solution system (FMPS, Functional Mathematical Programming System),
- 3) a report writer to translate the linear programming solution into useful information for decision making.

The majority of the Forest's analysis, including the final alternative runs, was done using Version II, Release 12 of FORPLAN. The system is maintained and operated on the Department of Agriculture's Univac computer at Fort Collins, Colorado.

Linear Programming (LP) is a mathematical modeling technique used to solve a series of simultaneous linear equations, such that one criterion is maximized or minimized, subject to meeting all specified constraints. Pertinent information about the Forest must be translated into linear equations in order to apply linear programming to the planning problem. This task was performed by the Interdisciplinary Team.

The FORPLAN model for the Wenatchee was specifically designed to aid the Interdisciplinary Team in analyzing how the various alternatives addressed the identified issues, concerns, and opportunities.

The first step in building the FORPLAN model was deciding what factors needed to be incorporated to accomplish this. For example, land stratification included roading status because that was directly related to an issue and strongly influenced costs. On the other hand, land stratification didn't include elevation because that didn't relate to an issue and didn't strongly influence cost or output estimation.

The Forest was divided into "analysis areas." These are tracts of land with relatively homogeneous responses to management activities in terms of the outputs and effects that are being analyzed in the FORPLAN model. They are non-contiguous. A given analysis area can consist of a number of tracts of land scattered across the Forest.

Management prescriptions were developed to represent alternative ways of managing portions of the Forest. These prescriptions are unique combinations of scheduled activities and practices.

The application of management prescriptions to analysis areas results in various streams of costs, resource outputs, and associated benefits over time. These were estimated by the Interdisciplinary Team. FORPLAN's matrix generator translates these factors into coefficients for the linear programming model

Management prescriptions are allocated to analysis areas by FORPLAN, resulting in various mixes of goods and services. The mix of goods and services and the timing with which they are produced depends upon the constraints applied and the objective function specified. Constraints could be in the form of land allocations (e.g., a certain portion of the Forest must be assigned to a dispersed, non-motorized management prescription), output levels (e.g., a certain number of acres of old growth must exist), input levels (e.g., budget cannot exceed a certain amount), or fluctuation in output levels (e.g., timber harvested in one decade can't be less than the amount harvested in a previous decade). The objective function is one criterion (e.g., maximization of present net value) which is optimized subject to first meeting all constraints.

The final versions of all alternatives and benchmarks used an objective function of maximization of present net value over the 15 decade modeling horizon. Some alternatives and benchmarks were highly constrained, leaving little decision space available for meeting this criterion; others were not. In any case, the maximization of present net value, subject to meeting all constraints, provided a cost-efficient means of achieving objectives.

The FORPLAN model was not used to develop the No Change Alternative.

B. The Analysis Process and Analytical Tools

1. Analysis prior to FORPLAN

Public issues, management concerns, and resource use and development opportunities (ICO's) were identified over the entire period that the Land and Resource Management Plan was being developed. Most of the ensuing analysis was driven by these issues, concerns, and opportunities.

Much of the analysis prior to using the FORPLAN model involved determining how to build the model. Analysis areas were delineated, management prescriptions were developed, timing options were analyzed for prescriptions that harvested timber, and yield coefficients were developed. These processes are detailed in Subsections C, D, E, and F, respectively, of Section III of this Appendix. Costs, benefit values, and demands for various outputs were developed as described in Section IV. Minimum management requirements were developed as described in Section VI.B. The Forest was stratified according to its tentative suitability for timber harvest as described in Section II.A.

A socioeconomic overview of the Forest was prepared by a private consultant. Historic socioeconomic conditions were identified. IMPLAN, an input-output model for economic impact assessment, was developed. This is described and summarized in Section V.

Alternative NC is neither an integrated alternative, nor was cost efficiency explicitly addressed when it was developed. For this reason, requirements of 36 CFR 219.12(f)(8) may not be met.

Calculation of harvest level is based on the Austrian Formula for the ponderosa pine in the Wenatchee Working Circle. The Hanzlik's formula approach was used on the other species.

Stand table projection methods described later in this chapter were used to estimate timber yields and to develop harvest projection for Alternative NC on the Naches-Tieton Working Circle.

2 Use of FORPLAN in Analysis

FORPLAN was used to determine cost-efficient allocations and scheduling of resources for benchmarks and alternatives. Estimates of resource output levels, costs, benefits, and present net value were either derived directly from FORPLAN or in secondary models which used inputs derived from FORPLAN.

FORPLAN was used during the analysis of the management situation to determine the maximum production potentials of various Forest resources, the most cost-efficient ways of managing the Forest, and the impacts of certain laws, policies, and economic assumptions. This information was then used in the development of alternatives. FORPLAN was used to determine the most cost-efficient mix and timing of management activities, given certain land allocations, during the formulation and estimation of effects of alternatives. Both uses are explained in more detail below.

Some of the benchmarks examined during the analysis of the management situation determined the production level of Forest resources. A physical resource such as unroaded recreation capacity was first maximized. FORPLAN would then be constrained to produce that output level, while maximizing present net value. The first step determined the maximum ability of the Forest to produce a given resource. The second step determined the most cost-efficient allocation of management prescriptions and scheduling of activities and outputs necessary to achieve that production level.

Other benchmarks maximized present net value without having to first meet output targets. These benchmarks contained varied legal and policy constraints and economic assumptions in order to test their impacts. Among those things tested were minimum management requirements, nondeclining even flow and rotation age policies, and assumptions as to benefit values, costs, and price trends. Another benchmark was developed to simulate the current management of the Forest projected into the future.

Detailed descriptions of the benchmarks, their constraints and assumptions, and the results of the analysis can be found in Sections III and VIII of this appendix.

Preliminary work with the FORPLAN model indicated that it did not contain enough site-specific detail to make meaningful land allocation decisions. Inventory data was not available for every specific acre of the Forest. Much of the data available was accurate as an average over a broad area of the Forest but not for any one specific spot. Also, many of the factors important to allocation decisions, particularly those involving spatial juxtaposition, could not be meaningfully specified as linear equations for FORPLAN. Because of these reasons, land allocation decisions were made outside of the FORPLAN model.

The Forest Management Team, in some cases with input from various citizens groups and industry, developed six alternative land allocations. The alternatives are described in detail in Chapter II of the FEIS and in Section VII of this appendix. These were first drawn on paper, then input into R2MAP. The land allocations were overlaid with analysis areas in R2MAP to determine the number of acres of each analysis area which were allocated to a given management prescription in each alternative. This information was used to constrain the FORPLAN model to those allocations.

Choices as to management intensity and timing of management practices were still available within the more general land allocations. For example, lands allocated to the General Forest Management Prescription had five different intensities (different levels of precommercial thinning, commercial thinning, regeneration harvest, and reforestation) available and a broad range of timing choices within each intensity.

This technique ensured spatial feasibility and land allocation boundaries which made sense to the on-the-ground managers who would have to implement them. The land allocation decisions could be made

better outside of FORPLAN. Management intensity and scheduling choices involved information which could be more accurately portrayed in FORPLAN. Therefore FORPLAN was used to optimize management intensity and scheduling for each alternative's land allocation, given other goals and objectives.

A number of outputs and effects were directly estimated using FORPLAN. These include:

- allowable sale quantity (ASQ) by timber species
- total available forage
- livestock forage
- wildlife forage
- visual quality objectives (VQO's)
- recreation opportunity spectrum (ROS) class
- dispersed recreation capacity by ROS class
- background sediment
- activity sediment
- water yield increase

Much of this information was reported by Management Area, as well as Forest-wide. Timber management activities and outputs were reported by treatment type, working group, and in some cases, by species.

3. Analysis in Addition to FORPLAN Analysis

FORPLAN outputs were used as inputs for other analysis processes in some cases. Also some analysis was done totally independent from FORPLAN.

Changes in employment and income were estimated using IMPLAN, an input-output model. Changes in timber harvest, livestock forage production, and dispersed recreation use were developed with FORPLAN. Changes in developed recreation use and firewood gathering were estimated outside of FORPLAN. Changes in these physical outputs were translated into changes in employment and income using an electronic spreadsheet and coefficients generated with IMPLAN. The Forest's IMPLAN model is discussed in Section V of this appendix.

Discounted costs and benefits by major resource group and present net value were estimated using an electronic spreadsheet. The variable costs and benefits which influenced allocation and scheduling decisions were taken from FORPLAN. Other costs and benefits were handled outside of FORPLAN. Economic efficiency analysis is detailed in Section IV of this appendix.

Budgets, returns to the U.S. Treasury, and payments to local governments were estimated using electronic spreadsheets. Some of the inputs to these calculations were taken directly from FORPLAN, others were estimated by hand. More detail can be found in Sections IV and V of this appendix.

The arterial and collector road system was estimated outside of FORPLAN based on the land allocation of each alternative. A more generalized estimate was made for all benchmarks. Local road construction was adjusted after FORPLAN analysis to reflect additional access requirements of currently unroaded areas.

Other outputs and effects estimated outside of FORPLAN included:

- developed recreation capacity and use
- wilderness recreation capacity and use
- firewood
- trail construction and reconstruction
- wildlife and fish habitat, improvements, and populations
- range improvements
- watershed improvements
- human resource programs
- minerals and energy development and access
- fire effectiveness index

C. Identification of Analysis Areas

One of the first steps in the development of FORPLAN was to divide the Forest into analysis areas.

Analysis areas are tracts of land with relatively homogeneous characteristics in terms of the outputs and effects that are being analyzed within the FORPLAN model. They serve as the basic unit of land in the model, for which a range of prescriptions are developed to achieve various multiple use objectives. Their delineations were intended to capture the significant social, biological, and economic differences in the way the land responds to alternative management strategies, and to keep the model size reasonable so that projected analysis steps could be completed quickly and at a reasonable expense. The focus of delineating analysis areas was upon addressing certain issues, concerns, and opportunities identified at the outset of the planning process.

The following discussion presents the rationale behind the identification and delineation of the analysis areas according to six FORPLAN categories or levels of identifiers. The organization of identifiers within each level is designed to generate the least number of analysis areas consistent with the complexity of the Forest and the planning problem. Each FORPLAN level identifier becomes an increasingly more detailed description of the division of lands in the previous level.

Analysis areas were not used to develop Alternative NC as they were with other alternatives.

Level 1

Level 1 provides the legal and mutually exclusive management status identifier for each analysis area. The first 14 identifiers are for areas of the Forest that were not analyzed in detail by the subsequent identifier levels. The last two identifiers reflect the roading status of the remainder of the Forest.

<u>LEVEL 1</u>	<u>MANAGEMENT STATUS</u>
1	NATIONAL FOREST LAKES AND RIVERS WITHIN WILDERNESS
2	NATIONAL FOREST LAKES AND RIVERS WITHIN ROADED AREAS
3	NATIONAL FOREST LAKES AND RIVERS WITHIN UNROADED AREAS
4	WILDERNESS - TRAILLESS MANAGEMENT
5	WILDERNESS - TRAIL ASSOCIATED MANAGEMENT - PRIMITIVE
6	WILDERNESS - TRAIL ASSOCIATED MANAGEMENT - SEMI PRIMITIVE
7	WILDERNESS - TRAIL ASSOCIATED MANAGEMENT - TRANSITION
8	UTILITY CORRIDORS
9	ADMINISTRATIVE SITES - OTHER THAN UTILITY CORRIDORS
10	SPECIAL USES
11	ACRES IN ARTERIAL AND COLLECTOR ROADS AS OF 1984
12	BOTANICAL AREAS
13	EXPERIMENTAL FOREST
14	SIGNIFICANT CULTURAL SITES
15	UNROADED AREAS (EXISTING)
16	LANDS ACCESSIBLE BY ROADS

The "unroaded area" delineation indicates areas that would have to incur up-front road construction costs for access before any timber management activities could be scheduled in them. Unroaded areas have different roading costs based on slope and soil hazard conditions. Their delineation also facilitates the tracking of scheduled activities in unroaded areas.

Level 2

Level 2 is not used in this version of the Wenatchee model. This level was reserved for use in case the FORPLAN Coordinated Allocation Choice feature was used for geographic locators. Specific geographic areas such as Ranger Districts and watersheds were not used since yield coefficients available for this round of planning are not accurate to that level of detail.

Level 3

Level 3 provides the vegetative type identifier for each analysis area. These identifiers are important for predicting timber, forage, water, and sediment yields.

<u>LEVEL 3</u>	<u>VEGETATIVE TYPES</u>
1	NO ADDITIONAL VEGETATIVE TYPE SPECIFIED
2	NON-VEGETATED LANDS
3	VEGETATED NON-FOREST LANDS
4	FOREST LAND UNSUITABLE FOR TIMBER PRODUCTION
5	FOREST LAND - DRY MODEL COMPONENT
6	FOREST LAND - WET MODEL COMPONENT

Level 4

Level 4 provides the existing timber stand condition classification for lands tentatively suitable for timber production. This level describes the current status of both vegetated and nonvegetated lands. It is used primarily to identify which silvicultural systems and timing options were appropriate to consider on tentatively suitable and available forested lands. It also is used to help monitor the effects of alternative harvest schedules on the vegetative successional stages as related to wildlife habitat requirements.

<u>LEVEL 4</u>	<u>CONDITION CLASS</u>
1	NO ADDITIONAL CONDITION CLASS SPECIFIED
2	MATURE TIMBER STANDS - CFL
3	IMMATURE SINGLE STORY TIMBER STANDS - CFL
4	IMMATURE UNDERSTORY W/SCATTERED MATURE OVERSTORY TIMBER STANDS - CFL
5	SEEDLING AND SAPLING TIMBER STANDS - CFL
6	BARE GROUND AVAILABLE FOR REFORESTATION ACTIVITIES - CFL

Level 5

Level 5 provides three slope classifications and two soil hazard classifications for each analysis areas. Slope is included as an identifier due to it's effect on logging costs, sediment yields, wildlife and livestock AUM's, and costs and miles of road construction. Soil hazard influences sediment yields.

<u>LEVEL 5</u>	<u>SLOPE AND SOIL HAZARD</u>
1	NO ADDITIONAL SLOPE OR SOIL SPECIFIED
2	GENTLE SLOPE <40% - LOW TO MODERATE SOIL HAZARD
3	GENTLE SLOPE <40% - HIGH SOIL HAZARD
4	MODERATE SLOPE 40-60% - LOW TO MODERATE SOIL HAZARD
5	MODERATE SLOPE 40-60% - HIGH SOIL HAZARD
6	STEEP SLOPE >60% - LOW TO MODERATE SOIL HAZARD
7	STEEP SLOPE >60% - HIGH SOIL HAZARD

Level 6

Level 6 is not used in this version of the Wenatchee model. No further differentiation of land characteristics was needed.

Analysis areas used in the FORPLAN model are listed in Table B-III-1 Outputs and effects for the first 14 analysis areas were estimated outside of FORPLAN. These areas were subdivided as needed to estimate each output. They are also included in the FORPLAN model so that all net National Forest acres are accounted for.

Major factors which affected the delineation of analysis areas are summarized below.

1. Economic Factors

Timber working groups are composed of different mixes of species. Values vary by species. Splitting the tentatively suitable timber lands into two working groups allowed more specific values to be used. A more detailed split was not feasible due to the stratification of the timber inventory used.

An important function of slope class identifiers is to reflect cost differences. Logging costs are strongly influenced by slope due to its influence on the type of logging system used. Road construction costs vary significantly between slope classes.

2. Inventory and Data Reliability

Greater geographic specificity was not included in the analysis areas due partially to a lack of site specific data. Forest-wide yield coefficients were all that was available for many resources. It is important to have specific differences in coefficients between analysis areas. Otherwise an element of randomness is introduced into model linear programming solutions which can make interpretation difficult.

Timber vegetative types could not be stratified in greater detail due to the location of sample plots. A third vegetative type consisting of lodgepole pine and mountain hemlock was desired but only one inventory plot would have been located in this vegetative type. Approximately 5,000 acres of lodgepole pine and mountain hemlock was combined with the forest-wet vegetative type.

3. Computer Model Characteristics

The FORPLAN software placed no limitations on analysis area delineation. The Forest did not even approach the software limitations. The cost of processing FORPLAN on the USDA's Fort Collins Computer Center did influence analysis area delineation. Analysis areas of less than 1,000 acres were aggregated with other analysis areas with similar characteristics when possible.

A model size which allowed fairly quick computer turn-around time and reasonable cost was considered an advantage in being able to do more analysis within a given timeframe and budget. A small enough model to allow clear comprehension and analysis was also desired.

4. Reporting Needs

The roaded versus unroaded analysis area split is in response to the issue of roadless area management as well as to reflect cost differences. The working group and slope classes allow easier ties back to the ground.

5. Legal or Policy Constraints

Analysis area delineation was not influenced by legal or policy constraints.

6 Spatial versus Biological Factors

The analysis areas were considered to be the minimum necessary to reflect biological and economic factors which strongly influenced allocation and scheduling decisions. The addition of additional spatial information would have greatly increased model size and cost. The necessary data to reflect many spatial relationships was also not available.

D. Identification of Prescriptions

1. Overview

National Forest Management Act regulations define management prescriptions as “management practices selected and scheduled for application on a specific area to attain multiple use and other goals and objectives” (36 CFR 219.3). They consist of a goal statement which establishes the purpose of the prescription, and a compatible set of management practices designed to develop and/or protect some combination of resources and create or perpetuate a desired condition. They were constructed within the requirements specified in 36 CFR 219.27, which guide the development, analysis, approval, implementation, monitoring and evaluation of Forest Plans with regard to resource protection, vegetative manipulation, silvicultural practices, even-aged management, riparian areas, soil, water, and diversity.

The process of identifying and subsequently developing management prescriptions began with an Interdisciplinary Team review of the issues, concerns, and opportunities (ICO’s). Prescriptions were then identified which would help address those ICO’s which were related to decisions regarding standards and guidelines, scheduling, or land allocations. There were other ICO’s which were to be addressed through policy statements for which it was not appropriate to develop prescriptions.

Once the need and purpose for certain types of prescriptions was identified, goal statements for each management prescription were designed to respond to the questions raised by the ICO’s. The Interdisciplinary Team then used professional judgment, evaluated existing policy, legislative direction, and research for guidance in developing multiple use management prescriptions. Regional Office and Ranger District personnel, representatives from other agencies, and interested members of the public participated in this process. The resulting management prescriptions then received thorough review, with some modification, by the Forest Management Team.

The resulting set of prescriptions represents a broad range of resource management emphases, practices, and capital investment levels. Forest-wide standards and guidelines were also developed by the Interdisciplinary Team and Management Team to cover practices common to all prescriptions and resource management situations that are Forest-wide in scope.

In addition to addressing issues, concerns, and opportunities, the process of designing management prescriptions was also guided by the following criteria: (1) prescriptions should be achievable and contain realistic practices, (2) they are to be general enough to accommodate the variable site specific conditions on the ground, (3) they should be specific enough for the Interdisciplinary Team to develop accurate resource and economic output and effects coefficients, and (4) to the extent practical, they should be the most cost effective means of achieving the intent of the prescription.

Each management prescription developed by the Interdisciplinary Team was modeled in FORPLAN. Analysis areas were screened to determine which were appropriate to be managed under each prescription. The full range of prescriptions was available to most analysis areas, with the exception of specially designated areas and their prescriptions such as wilderness or administrative sites. FORPLAN was then used to evaluate the implications of alternative land allocation and scheduling choices.

Prescriptions were not developed for Alternative NC according to criteria in 36 CFR 219.11 and 36 CFR 219.27. Five classifications were used in the 1969 Naches-Tieton and 1963 Wenatchee Timber Management Plans. They corresponded with appropriate classifications in District Multiple Use Plans.

Industrial. Lands managed under “standard” rotations that have “a reasonable probability of demand under the accessibility and economic conditions projected for the plan period” and that “can be logged under the contract constraints necessary to protect the resource.”

Modified. Lands that should receive special attention mainly because of landscape management considerations. This component is divided into two classes:

Modified-Full Yield. Areas which require constraints on harvest associated with higher costs, but where full yield will occur.

Modified-Partial Yield. Areas which require constraints on harvest operations that will reduce per acre yields or lengthen rotations. For the 1969 Naches-Tieton Timber Management Plan, Modified-Partial Yield produced 50 percent of industrial yield volumes. The Wenatchee Timber Management Plan used estimated gross annual growth of 131 board feet per acre for landscape management areas.

Marginal. Areas where harvesting is silviculturally desirable but that has a low probability of being purchased. Lodgepole pine and commercial thinnings were placed in the Marginal component on the Wenatchee Working Circle. This cut component was not used on the Naches-Tieton Working Circle.

Deferred. The areas where harvesting is precluded pending legislation.

Unregulated. Areas where unscheduled harvest is permitted such as recreation sites, administrative areas, or experimental forests. Also included is material that does not meet utilization standards and presently economically inoperable areas.

2. Purpose, Criteria, and Assumptions

The activities composing each prescription represent the most cost efficient means of achieving the goals of the prescription. The use of cost efficient prescriptions in combination with maximizing present net value as an objective of FORPLAN, contributes to cost efficient alternatives. Each prescription, including standards and guidelines, and activity statements, is found in the Forest Plan. A detailed examination of prescriptions by analysis area can be found in the planning records at the Forest Supervisor's Office. The prescriptions are summarized below.

a. EF-1 (Experimental Forest)

GOAL STATEMENT: Provide opportunities to study the effects of Forest management and fire on vegetative, soil, and water resources occurring on the east side of the Cascade Mountains. Maintain the area in a form that will not compromise the opportunities for research.

DESCRIPTION: The Entiat Experimental Forest was designated under the authority of the Chief of the Forest Service in 1970. Burned by wildfire in 1970, and rehabilitated and reforested in subsequent years, the area has been the subject of numerous scientific investigations. Currently the Experimental Forest is being managed for a wide range of multiple uses in coordination with the Forestry Sciences Laboratory in Wenatchee. Periodic monitoring will occur until vegetation reaches such a size as to have a significant effect on water production. New studies will be initiated at that time.

Objectives following the Entiat Burn in August 1970 were to study the effects of fire on complete hydrologic units.

b. EW-1

GOAL STATEMENT: Manage deer and elk winter range to meet habitat requirements for sustaining optimum carrying capacity.

DESCRIPTION: Deer and elk winter ranges are generally on the edge of the Forest, adjacent to or intermingled with, other land ownerships, at low elevations, south and/or east facing slopes with reduced snow depth and early melt-off of snow. Because of these conditions these areas are highly desired for winter and/or early spring recreation activities and dry out early to become high fire danger areas. These habitats have openings covering 10 to 60 percent of the area (used by big game for foraging), containing shrubs, grasses, and forbs with scattered conifer trees, and 20 to 80 percent covered by conifer stands (used by big game for cover). The quality of the forage and the amount of thermal cover combined with the amount of human disturbance are the factors that determine the carrying capacity of these areas for big game in winter.

c. EW-2

GOAL STATEMENT: Maintain and enhance riparian management areas to perpetuate their distinctive resource values to (a) achieve and maintain habitat conditions necessary to maximize long-term natural production opportunities for desired fish species, (b) maintain water quality that meets or exceeds State Standards and (c) provide diverse wildlife habitat.

DESCRIPTION: This prescription applies to the land and vegetation adjacent to fish bearing streams, lakes and wetlands. The Riparian Management Area (RMA) shall correspond to at least the recognizable area dominated by riparian vegetation (true Riparian Zone) and sufficient upland area (influence area) to assure adequate protection to achieve riparian management objectives and standards. The minimum area of consideration is 100 feet horizontal distance from both the ordinary high water line associated with banks of fish bearing streams and the perimeter of lakes and wetlands.

Riparian Management Area boundaries and specific riparian management objectives will be established for all projects within an RMA. Riparian management objectives will be established based upon analysis of RMA habitat conditions, objectives and standards both within the sub-drainage (generally 1,000-10,000 acres) and at the project site.

Within Riparian Management Areas, management decisions will be made in favor of riparian dependent resources (water quality, fish and wildlife habitat) when conflicts exist with man's use.

Refer to the Forest-wide Standards and Guidelines for Riparian Areas for overall direction on the planning and administration of management activities in RMAs. The interim quantitative standards applicable to EW-2 are also listed under the heading RIPARIAN in the following prescription, along with some of the operational considerations associated with the standards (under "MANAGEMENT PRACTICE"). Refer to the "Administration" section in the Forest-wide Standards and Guidelines for Riparian Areas for a discussion of the use and refinement of these interim standards.

d. EW-3

GOAL STATEMENT: Manage deer, elk, and mountain goat winter range and key summer range to meet habitat requirements for sustaining optimum carrying capacity in an unroaded setting.

DESCRIPTION: Deer and elk winter ranges are generally at low elevations, on south and/or east facing slopes with reduced snow depth and early melt-off of snow. Because of these conditions, these areas are highly desirable for winter and early spring recreation activities, and dry out early to become high fire danger areas. These habitats have 10-60 percent of the area in openings (used by big game for foraging)

containing shrubs, grasses, and forbs with scattered conifer trees, and 20-80 percent of the area in conifer stands (used by big game for cover). The quality of the forage and the amount of thermal cover combined with the amount of human disturbance are the factors that determine the carrying capacity of these areas for big game in winter. Mountain goat summer and winter ranges are generally adjacent to each other at high elevations, well within the Forest, and just above and below the line separating suitable and unsuitable timber harvesting stands. Summer range consists of dense stands of old conifer trees intermingled with small meadows that provide food and shelter. Winter range consists of open, steep, rocky ridges with grasses, forbs, and shrubs dominating a landscape containing scattered conifer trees. Human activity, reductions in winter habitat, and lack of quality forage in summer range limit the populations of mountain goats.

e. GF (General Forest)

GOAL STATEMENT: Provide for the greatest long-term growth and production of commercially valuable wood products at a level of investment in timber cultural practices that maximizes net public benefits.

DESCRIPTION: Future stands will vary from intensive timber management typified by regular spacing, relatively even age and height, to those that are similar to natural stands. Regenerated stands will have a high ratio of genetically superior stock and may receive cultural treatments throughout the rotation. The cultural practices will be determined on a site specific basis depending on the biological and economic conditions of the stand. Regeneration harvest will generally occur at culmination of mean annual increment. Logging will be by the most economical methods compatible with silvicultural requirements, soil and water standards and landform. Road densities and standards would also be dependent upon these conditions. In the General Forest area, the relative intensity of management is set by the Forest Plan. However, site specific details and locations of treatments will be determined in the prescription written or field reviewed by a certified silviculturist.

e. MP-1

GOAL STATEMENT: Manage area to maintain and enhance its outstanding scenic and recreation qualities.

DESCRIPTION: This is an area classified by executive order, encompassing a zone extending 1/2 mile either side of U.S. Highway 410, to be managed primarily for scenic and recreational purposes. Developments and management activities within the allocation generally are not visually evident. The natural existing or established landscape will generally have vegetation on forested lands that is composed of large old growth trees in the overstory or in groves intermixed with a variety of age classes in the understory. The general perception of the landscape is a natural appearing environment. Motorized use is permitted within these areas to the extent it is compatible with the management intent.

f. OG-1

GOAL: Manage for old growth habitat to achieve "ecosystem diversity, preservation of aesthetic qualities", and/or "wildlife and plant habitat".

DESCRIPTION: The Regional Guide for the Pacific Northwest Region directs all Forests to use a standard definition of old growth. Following are the descriptions of the characteristics needed to meet the requirements of this prescription.

1. **ECOSYSTEM DIVERSITY:** Ecosystem diversity is a representation of the variety that exists in biotic communities and is characterized by the number of species on a site and by the number of communities at all sites. The variety of management prescriptions will provide many and varied stand conditions and species, helping to maintain ecosystem diversity in managed, younger stands. However, enough of all types of old growth are required to maintain species dependent on old growth and preserve the various kinds of old growth communities found on the Forest.

2. **PRESERVATION OF AESTHETIC QUALITIES:** People using the forest for recreation purposes enjoy old growth trees for their aesthetic and awe-inspiring qualities. Old trees represent a living link with the past and provide an important visual reference to the natural successional process of the forest environment.

Old growth stands are typically thought of as having an atmosphere that is peaceful, cathedral-like, and park-like or an atmosphere of being small, closed in, dominated and encompassed. The stand feels cool and refreshing, and smells musty from the decaying vegetation (rotting logs, snags, fruiting bodies of fungus and underbrush). The trees have deep furrowed bark, large diameters at the base of the tree (generally 21" in diameter or larger), tall and straight boles, (over 100 feet tall) rotten cracks, broken limbs, mosses, lichens, and rounded tops that create the illusion of being old.

3. **WILDLIFE AND PLANT HABITAT:** The indicator species for old growth and mature habitat is the spotted owl. Habitat for spotted owls includes mature and overmature trees dominant in the overstory, a multi-layered canopy, trees of several age classes, large amounts of standing dead trees and down material present, canopy crown closure of 45 percent or greater, and elevations between 1500 and 5000 feet

The 2200 acres (more or less depending upon local circumstances) of suitable habitat may be contiguous, or scattered over a area of about 9000 acres. There is usually unsuitable habitat (either naturally occurring or from harvest) intermingled with the suitable habitat. It is common to find logging activities next to suitable spotted owl habitat. Road use and recreation activities will often be taking place within the habitat site.

Maintenance of reproduction of spotted owls is of high concern. Therefore, activities that may affect reproduction will be limited.

g. OG-2

GOAL STATEMENT: Manage for mature to old growth habitat for wildlife and plant species dependent upon this habitat.

DESCRIPTION: The indicator species for this prescription are the marten/northern three-toed woodpecker and pileated woodpecker. These indicators plus the spotted owl are designed to provide a mature and old growth network. The network is to provide habitat for all species dependent upon mature or old growth habitat. The habitat for the marten/northern three-toed woodpecker and pileated woodpecker is described as mature or overmature trees in the overstory, a multi-layered canopy of trees in several age classes, large amounts of dead standing and down trees present, and a canopy closure of 45 percent or greater. Habitat for marten/northern three-toed woodpeckers is at elevations of about 2000 to 7000 feet, and for the pileated woodpecker, about 1500 to 5000 feet in elevation.

The marten/northern three-toed woodpecker habitat is a 160 acre contiguous habitat. One site will be found every 4000 to 5000 acres and it will be overlapped with spotted owl and pileated woodpecker sites when possible. An additional 160 acres of habitat is needed for developing future marten/northern three-toed woodpecker habitat. This additional acreage may be in any successional stages. The location of the 160 acres of mature habitat will change through time in the 320 acre site.

The pileated woodpecker habitat is 300 acres, made of stands of no less than 50 acres within a 1000 acre area. One site will be found every 12,000 acres and these sites should be overlapped with spotted owls when possible. An additional 300 acres of habitat is needed for pileated woodpecker sites that may be in any successional stage but must have a high number of snags to provide food. The location of the 300 acres of mature habitat will change through time in the 600 acre site.

h. RE-1

GOAL STATEMENT: Provide developed recreation in an Urban to Semi-Primitive Recreation Opportunity Spectrum (ROS) setting.

DESCRIPTION: This prescription is applicable to existing and potential developed recreation sites within the full spectrum of ROS settings. The areas allocated to this use include only the specific site on which development takes place. This prescription is also applicable to existing and potential Alpine (downhill) ski areas including runs, tows or lift facilities, shelters, lodges, services and parking lots. Associated developments such as skating rinks, toboggan runs, etc., may also be present. Potential sites allocated to this prescription will be managed to protect or enhance the future values and conditions desired.

i. RE-2

GOAL STATEMENT: Provide dispersed, unroaded recreation in a semi-primitive motorized recreation opportunity setting.

DESCRIPTION: This prescription is for application to unroaded areas in which trails are evident and maintained for the following types of uses:

RE-2A. Areas having existing or potential trails for motorbikes, hikers and horseback riders.

RE-2B. Areas having existing or potential 4x4 routes in addition to trails for motorbikes, hikers and horseback riders.

They are generally located in a natural appearing landscape setting. Winter motorized use is permitted where appropriate.

j. RE-3

GOAL STATEMENT: Provide dispersed recreation in an unroaded, semi-primitive, non-motorized or primitive setting.

DESCRIPTION: This prescription is for application to unroaded areas in which trails are evident and maintained for non-motorized users. Landscape changes are generally not evident to those walking through the area. The area is essentially a natural or natural appearing environment. There is little evidence on-site of other users.

k. RE-4

GOAL STATEMENT: Provide for dispersed recreation, as well as long-term growth and production of commercially valuable wood products at a very low level of investment in timber cultural practices while maintaining the unroaded characteristics.

DESCRIPTION: *Approximately 90 percent of future stands would come from natural regeneration. The remaining 10 percent would be regenerated by planting, after failure of natural regeneration to establish the stand. No stand improvements are planned between regeneration and harvest, future stands will closely resemble unmanaged conditions and will be typified by a tendency towards small irregularly spaced groups. Stands will generally have poor crown ratios and a wide range of age and height. Mortality due to tree competition, disease, and insects can be expected. Logging will generally be by aerial system to protect the unroaded characteristics of the area. Roads will not be constructed, except to protect adjacent resources.*

l. **RM-1**

GOAL STATEMENT: Provide for maximum forage production and utilization by commercial livestock with a high level of investment in range cultural practices.

DESCRIPTION: Management seeks to optimize production and utilization of forage allocated for livestock use consistent with maintaining the environment and providing for multiple use of the range. Cultural practices such as brush control or seeding may be combined with fencing and water developments to implement complex grazing systems.

m. **RN-1**

GOAL STATEMENT: Provide for; (1) Preservation of examples of all significant natural Ecosystems for comparison with the influenced by man, (2) educational research areas for ecological and environmental studies, and (3) preservation of gene pools for typical and rare and endangered plants and animals.

DESCRIPTION: Research Natural Areas (RNA) contain either examples of typical natural ecosystems or unique kinds of vegetation, animals, and land which are reserved for scientific and educational use. This use is restricted to non-manipulative and non-destructive research. On the Wenatchee National Forest there are two established RNAs: Meeks Table and Thompson Clover. Two additional areas have been studied and are candidates for addition to the system. They are: Fish Lake, a marsh-bog community, and Eldorado Creek, a montane serpentine community. Several new areas on the Forest are candidates as Research Natural areas to meet regional cell (ecosystem) needs. A Research Natural Area establishment report will be prepared for each recommended area when the Forest Plan is implemented. These reports will describe the boundaries of the areas. Until the reports are signed by the Chief of the Forest Service, the areas designated in this Plan are recommendations. They will be managed to maintain their suitability as RNAs.

n. **SI-1**

GOAL STATEMENT: Manage Special Areas for recreation use, substantially in their natural conditions.

DESCRIPTION: These areas are classified under 36 CFR 294.1 and managed for recreation use substantially in their natural condition. The purpose of classifying these areas is to protect the natural beauty and, where appropriate, foster public use and enjoyment of the feature or environment (scenic areas possess outstanding or unique natural beauty). They occupy large areas of land where some multiple use activities may be compatible. Motorized use is permitted within these areas to the extent it is compatible with the management intent. Developments such as resorts, parking areas, campgrounds, etc., are located outside of the Special Area whenever possible.

o. SI-2

GOAL STATEMENT: Manage areas of significant cultural, geological, botanical, zoological, paleontological, or other special characteristics so as to protect, preserve, and enhance their intrinsic values.

DESCRIPTION: Special Interest Areas are classified under 36 CFR 294.1 and managed for recreation use substantially in their natural condition. The purpose of classifying these areas is to protect, and where appropriate, foster public use and enjoyment of the feature or environment. This prescription includes the following:

- Cultural-Historic Area Lands possessing prehistoric or historical sites, buildings, or objects of National Register significance or having special cultural associations to the American Indian community.
- Geologic Area Lands having unique geologic features of the earth's development including caves and fossils.
- Botanical Area Lands containing specimens or group exhibits of plants, plant groups, and plant communities which are significant because of form, color occurrence, habitat location, life history, arrangement ecology, environment, rarity and/or other features.
- Zoological Area Those lands having authentic, significant and interesting evidence of our American National heritage as it pertains to fauna. The areas are meaningful because they embrace animals, animal groups, or animal communities which are natural and important because of occurrence, habitat, location, life history, ecology, environment, rarity or other features.
- Paleontological Areas Areas containing relic specimens of fauna and flora. These are the plant and animals (non-human) that span geologic time between periods when life first appeared on earth and the age of man. Significant specimens may include Precambrian rocks; shellfish, early vertebrates, coal swamp forest; early reptiles, dinosaurs; and Cenozoic mammals.

Management of these areas is aimed at preserving the features and environment of the area to be classified. Developments such as resorts, parking areas, campgrounds, etc., are located outside the special interest area whenever possible.

p. ST-1

GOAL STATEMENT: To retain or enhance the viewing and recreation experiences along scenic travel routes.

DESCRIPTION: Development and permitted uses will meet the "Retention" Visual Quality Objective in foreground and middleground areas viewed from developed recreation sites and designated roads and trails. Developments and management activities within the allocation generally are not visually evident. The natural existing or established landscape will generally have vegetation on forested lands that is composed of large old growth trees in the overstory or in groves intermixed with a variety of age classes in the understory. The general perception of the landscape is a natural appearing environment.

q. ST-2

GOAL STATEMENT: Provide a natural appearing foreground and middleground along scenic travel corridors.

DESCRIPTION: Development and permitted uses will meet the "Partial Retention" Visual Quality Objective in the foreground and middleground viewed from developed recreation sites and designated roads and trails. The foreground of the main use routes will generally have vegetation that is composed

of some large trees in the overstory or in groves intermixed with a variety of age classes in the understory. The middleground viewed areas from the main travel routes will generally have the perception of a natural appearing environment. The proposed uses and vegetation management within the allocation will be integrated with the natural landscape so that activities are visually subordinate to the characteristic landscape.

r. UC-1 (Utility Corridors)

GOAL STATEMENT: Provide and manage utility corridors to accommodate energy transmission needs.

DESCRIPTION: This prescription is applicable to existing and potential utility and transmission corridors. It includes the land directly under and adjacent to the pipeline or powerline facility (clearing limits). Compatible facilities are combined in the same corridor whenever possible. Resource uses, such as grazing, and dispersed recreation activities, such as camping, mushroom and berry picking, Christmas tree cutting, etc., may be compatible in some areas.

s. WI-1

GOAL STATEMENT: Preserve and protect the natural character for future generations, and provide opportunities for solitude, challenge, inspiration, and scientific study.

DESCRIPTION: This prescription is for application to the following Wildernesses: Alpine Lakes, Chelan-Sawtooth, Glacier Peak, Henry M. Jackson, Norse Peak, William O. Douglas, and Goat Rocks. Also, refer to the Alpine Lakes Area Management Plan for specific direction for the Alpine Lakes Wilderness.

Each wilderness is delineated into four wilderness Recreation opportunity classes. These classes are Pristine, Primitive, semi-primitive and transition. Each class represents a specific physical, biological, social and managerial setting and degree of isolation and solitude that can be experienced. Experiences range from the maximum solitude and freedom found in the Pristine Class to the more human impacted acres near wilderness boundaries and trailheads that are classified transition.

t. WS-1

GOAL STATEMENT: Preserve the Scenic River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

DESCRIPTION: This prescription is for application to those river segments on the Forest that are free of impoundments, and have largely primitive watersheds or shorelines but are accessible by road in places.

u. WS-2

GOAL STATEMENT: Preserve the Recreational River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

DESCRIPTION: This prescription is for application to those river segments on the Forest that are readily accessible by road or railroad, may have some development along their shorelines, and may have undergone some impoundment or diversion in the past.

GOAL STATEMENT: Preserve the Wild River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

DESCRIPTION: This prescription is applicable to those river segments that are free of impoundments and generally inaccessible except by trail, with watersheds or shoreline essentially primitive and waters unpolluted. These represent vestiges of primitive America.

E. Development of Timber Options

Timber harvest options and management intensities were developed to: (1) Portray a range of investment levels and silvicultural treatments that are technologically feasible and sound for each vegetative type and condition class; and (2) to evaluate the yield and economic consequences utilizing the FORPLAN model.

A range of silvicultural prescriptions was developed and analyzed for each vegetative type and management prescription combination. This included the development of both empirical and managed yield tables. Once the management prescriptions were identified which were needed to address issues, concerns, and opportunities, the Interdisciplinary Team determined which of them could have their objectives achieved through scheduled (regulated) timber harvesting.

Based on an analysis of the Continuous Forest Inventory (CFI) plot data, forested areas were stratified according to their existing inventory characteristics. Empirical yield tables are used to portray alternative silvicultural treatment options for existing mature sawtimber stands, immature two-storied stands, and immature pole stands. The silvicultural prescriptions, and their associated yield tables as developed, are based on regression analyses of the CFI plot data plus professional judgment. As would be expected, the older the stand, the fewer the silvicultural options that are realistically available to manage it. Managed yield tables were developed for existing seedling/sapling stands and future managed stands using a growth simulation model.

Once the vegetative management objectives were identified for each management area, the appropriate Interdisciplinary Team members worked together to develop a range of harvest scheduling options. The overriding criterion in this process was that the silvicultural prescription and its associated yield table achieve the vegetative management objectives of the management prescription in a cost-efficient manner.

FORPLAN prescriptions are identified and described in terms of "management emphasis" and "management intensity." In most cases, the management emphasis name in FORPLAN is the same as the management prescription name used in the FEIS and Forest Plan. For example, ST-1 (Scenic Travel Retention) is the name of a management prescription and a FORPLAN management emphasis.

FORPLAN timber management options were developed for every combination of management prescriptions which called for scheduled harvesting and analysis areas which contained tentatively suitable acres. For each prescription, the several timing combination of choices were available to implement various practices. Also, for each management emphasis and analysis area that allowed timber harvesting, an option was available which called for no programmed harvest.

The silvicultural options that were developed for each of the management emphasis are referred to as "management intensities" in FORPLAN. They reflect different combinations of practices. In essence, they represent alternative investment levels in timber management to achieve the objectives of a management prescription.

A range of timing choices, rotation ages, and investment levels was developed for regenerated stands and existing seedling/sapling stands. The growth Prognosis Model (Wykoff and others 1981) was utilized to predict timber yields for various silvicultural systems and intensities for each combination of vegetative type and condition class.

The management intensities developed for General Forest management emphases evolve from three basic silvicultural schemes:

Extensive: Following satisfactory reforestation, no further treatment would be planned until final harvest [GF-4 (clearcut) and GF-6 (shelterwood)].

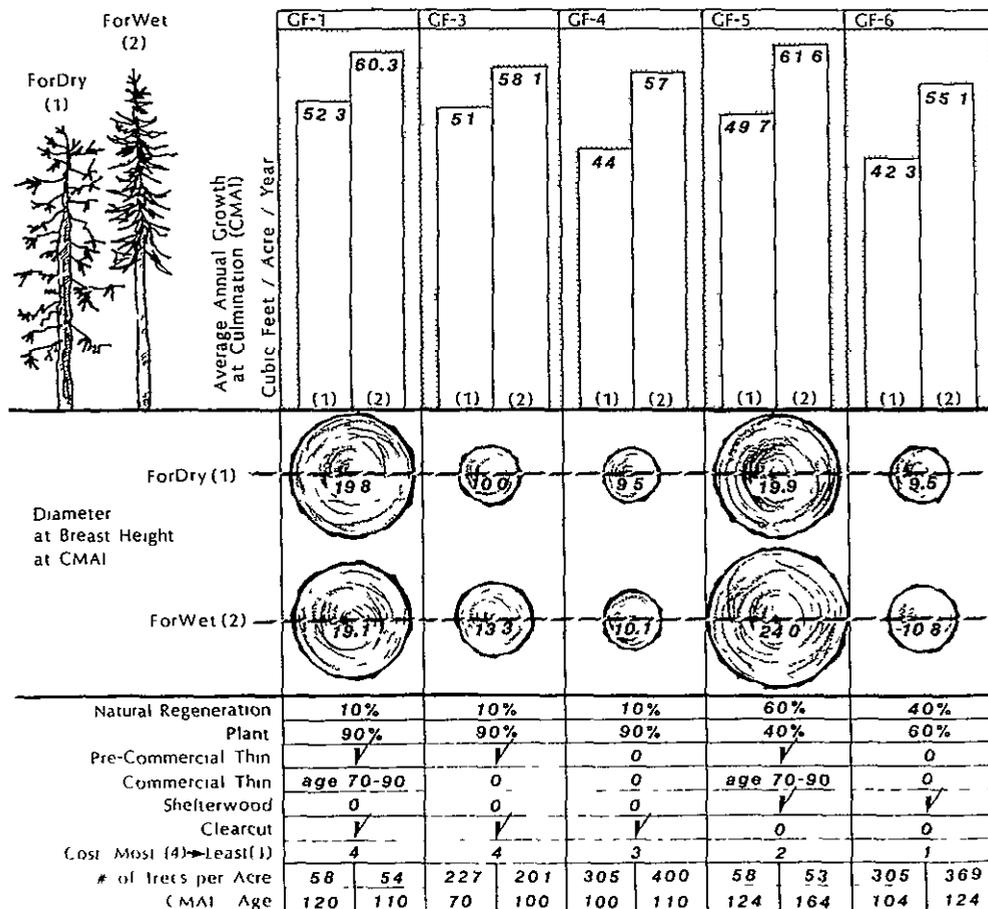

Moderate Intensity: Following satisfactory reforestation, stands would be precommercially thinned or weeded as needed to achieve early stocking level control; then no further treatment would be planned until final harvest [GF-3 (clearcut)].

Intensive: Management practices would include all reforestation treatments, removal of overtopping or severely competing brush or grass, precommercial thinning, and commercial thinning as needed to cost efficiently optimize timber production [GF-1 (clearcut) and GF-5 (shelterwood)].

Commercial thinning without prior precommercial thinning (originally labeled as GF-2) was investigated but was not among the options available for FORPLAN because of low yield, high cost, and operational problems. Stands would not reach an adequate size for commercial thinning in a reasonable time period without prior stocking control by precommercial thinning.

Figure B-III-1 depicts the General Forest Prescription timber regimes.

FIGURE B-III-1

Timber options for Alternative NC were developed in the 1963 and 1969 Timber Management Plans. They differ considerably from options developed for all other alternatives. Timber options for Alternative NC are very broadly described for specific treatments such as reforestation or timber stand improvement.

Management emphases other than General Forest were restricted to silvicultural regimes designed to achieve specific resource objectives such as wildlife habitat or scenic viewsheds.

The Intensive Range Management (RM-1) Prescription assumes the same silvicultural practices as GF-1, but with a 10 year regeneration lag. Three extended-rotation timber yield regimes were developed for use with the following prescriptions:

Prescription

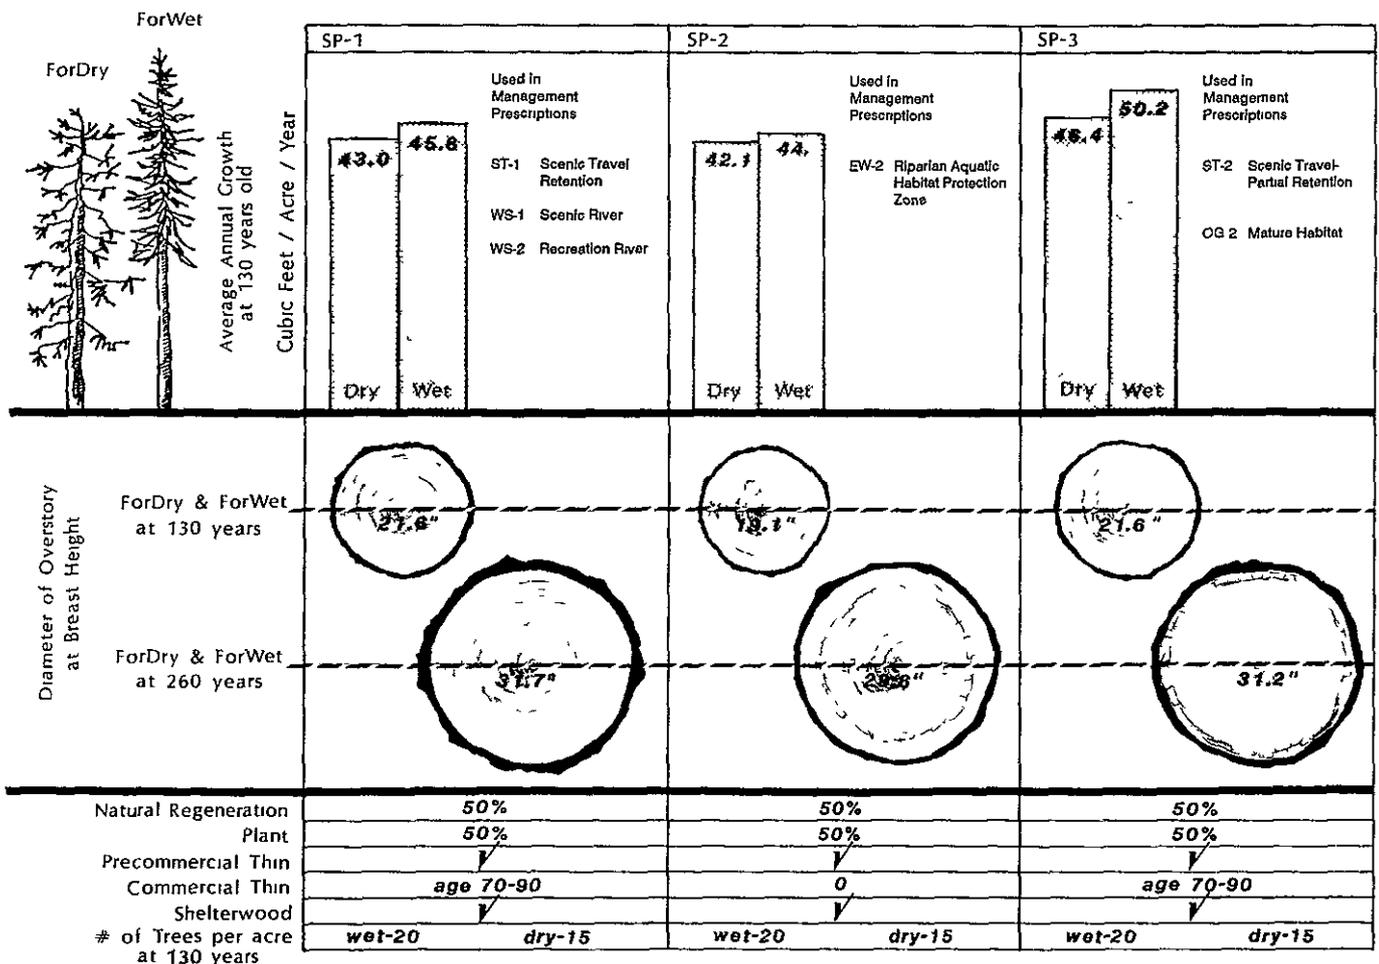

- Key Deer and Elk Habitat (EW-1)
- Riparian-Aquatic Habitat Protection Zone (EW-2)
- Old-Growth Dependent Species (OG-2)
- Scenic Travel-Retention (ST-1)
- Scenic Travel-Partial Retention (ST-2)
- Scenic River (WS-1)
- Recreational River (WS-2)

Yield Table

- RM-1(wet sites)
- SP-2
- SP-1
- SP-1
- SP-3
- SP-1
- SP-1

Figure B-III-2 depicts the extended-rotation timber yield regimes.

FIGURE B-III-2

A wide range of timing options for implementing silvicultural activities was available under the General Forest and Range Management Prescriptions so that harvest scheduling was not limited by a lack of available options. Stands could be regeneration harvested at any point from the period in which they reached culmination of mean annual increment (CMAI) through the end of the modeling horizon. Commercial thinning, if appropriate, could occur as soon as the minimum volume of economically feasible merchantable trees existed. The last entry age for commercial thinning was generally two decades prior to culmination of mean annual increment. Other management prescriptions had more restrictive timing options in order to meet other resource objectives. However, several timing choices were available for these prescriptions to reduce scheduling inflexibility.

As part of the benchmark analysis, rotations were also identified at the ages when stands first reach the minimum merchantability standards. These rotations were used to analyze the constraint of not harvesting prior to stands reaching 95 percent of CMAI.

Each of the management intensities include all management practices necessary to establish future stands; i.e., site preparation, animal control, reforestation (planting and natural), and release.

A list and brief description of the management intensities for timber harvesting emphases used in FORPLAN follows. A legend is presented first for clarification.

LEGEND:

FH	Final regeneration timber harvest
PLT	Reforest by planting and natural.
PCT	Stocking level control by precommercial thinning and release of competing vegetation
CT	Stocking level control by one or more commercial thinnings.
EXT. ROTATION	Extended rotation with shelterwood harvest occurring at age 130 years and final overstory removal at age 180 or 260 years
POR	Partial Overstory Removal

If an existing stand is mature, immature one-story, or immature two story, the management options are:

<u>EXISTING STAND</u>	<u>REGENERATED STAND</u>
FH	(GF-1) PLT,PCT,CT,FH
FH	(GF-3) PLT,PCT,FH
FH	(GF-4) PLT,FH
FH	(GF-5) PLT,PCT,CT,FH
FH	(GF-6) PLT,FH
FH	(RM-1) PLT,PCT,CT,FH
FH	(SP-1) PLT,PCT,CT,FH - EXT. ROTATION
FH	(SP-2) PLT,PCT,FH - EXT ROTATION
FH	(SP-3) PLT,PCT,CT,POR,FH - EXT ROTATION
EXTENSIVE MANAGEMENT (NO TIMBER HARVEST)	

If an existing stand is immature one or two-story, additional management options are:

<u>EXISTING STAND</u>	<u>REGENERATED STAND</u>
CT+FH	(GF-1) PLT,PCT,CT,FH
CT+FH	(GF-3) PLT,PCT,FH
CT+FH	(GF-4) PLT,FH
CT+FH	(GF-5) PLT,PCT,CT,FH
CT+FH	(GF-6) PLT,FH
CT+FH	(RM-1) PLT,PCT,CT,FH
CT+FH	(SP-1) PLT,PCT,CT,FH - EXT ROTATION
CT+FH	(SP-3) PLT,PCT,CT,POR,FH - EXT ROTATION
EXTENSIVE MANAGEMENT (NO TIMBER HARVEST)	

If an existing stand is seedling or sapling, the management options are:

<u>EXISTING STAND</u>	<u>REGENERATED STAND</u>
PCT+CT+FH	(GF-1) PLT,PCT,CT,FH
PCT+FH	(GF-3) PLT,PCT,FH
FH	(GF-4) PLT,FH
PCT+CT+FH	(GF-5) PLT,PCT,CT,FH
FH	(GF-6) PLT,FH
PCT+CT+FH	(RM-1) PLT,PCT,CT,FH
PCT+CT+FH	(SP-1) PLT,PCT,CT,FH - EXT ROTATION
PCT+FH	(SP-2) PLT,PCT,FH - EXT. ROTATION
PCT+CT+FH	(SP-3) PLT,PCT,CT,POR,FH - EXT. ROTATION
EXTENSIVE MANAGEMENT (NO TIMBER HARVEST)	

If an existing stand is bare ground, the management options are:

<u>EXISTING STAND</u>	<u>REGENERATED STAND</u>
PLT+PCT+CT+FH	(GF-1) PLT,PCT,CT,FH
PLT+PCT+FH	(GF-3) PLT,PCT,FH

PLT+FH	(GF-6) PLT,FH
PLT+PCT+CT+FH	(RM-1) PLT,PCT,CT,FH
PLT+PCT+CT+FH	(SP-1) PLT,PCT,CT,FH - EXT ROTATION
PLT+PCT+FH	(SP-2) PLT,PCT,FH - EXT. ROTATION
PLT+PCT+CT+FH	(SP-3) PLT,PCT,CT,POR,FH - EXT. ROTATION
EXTENSIVE MANAGEMENT (NO TIMBER HARVEST)	

The Wenatchee National Forest Tree Improvement Plan calls for a mixed level of tree improvement depending on species, tentatively suitable acres per seed zone, and cooperators interest. Availability of planting stock from select trees is expected to provide 85 percent of the total planting stock needed.

Planting of minor species not planned for tree improvement expenditures is expected to account for the remaining 15 percent. Planting grand-fir, Engelmann spruce, western red cedar, lodgepole pine, and subalpine fir as minor species is appropriate for the Wenatchee.

Natural regeneration is quite variable. According to regeneration surveys, stocking by natural regeneration ranges from zero to a high of almost 30 percent in the most favorable years with moisture following good seed production.

Assumptions as to natural regeneration versus planting were:

<u>Management Regime</u>	<u>Percent Natural</u>	<u>Percent Planted</u>
GF-1	10	90
GF-3	10	90
GF-4	10	90

GF-6	60	40
SP-1	50	50
SP-2	50	50
SP-3	50	50

F. Development of Yield Tables and Coefficients

This section describes how the yields for each resource, road construction, and sediment production were developed. Some yields were developed for analysis in FORPLAN and some were developed for analysis outside of the model. Only those yields used for analysis in FORPLAN are discussed here, except for portions of the recreation, water, and road yields, to clarify which yield segments were analyzed in the model and which were not.

1. Recreation Capacity

Recreation capacity by Recreation Opportunity Spectrum (ROS) class for dispersed recreation and wilderness was analyzed in the FORPLAN model.

Developed recreation was analyzed outside of FORPLAN. Capacity estimates were based on actual people at one time capacities for developed sites. Those capacities were converted to recreation visitor days through use of a formula developed to account for variables in demand for weekday versus weekend use, length of stay, and length of season.

Coefficients for Dispersed Recreation were developed first by tying the dispersed ROS classes to various recreation activities identified in the Recreation Information Management (RIM) System. Estimates of capacity by activity were made through consultation with specialists throughout the area in addition to experienced capacities on the Forest. A final check was made to determine if the results were within the range of capacities applicable to the Pacific Northwest Region.

The coefficients used for Alpine Lakes Wilderness were those developed for and used in the *Alpine Lakes Management Plan*.

For other wildernesses on the Forest, coefficients were similar to those used in Alpine Lakes except that further breakdowns in the trailed and trailless portions were based on updated ROS class terminology developed for wilderness.

A more detailed explanation of recreation coefficients is contained in the 1920 Land and Resource Management Files (14-4 Coefficient Analysis).

2 Forage Yields

In the development of forage yields, an average production was assigned to each vegetative type. The yield in pounds per acre was estimated from actual production measurements found on similar types on the Forest in addition to those documented in publications from Chelan County (S.C.S.), and Washington and Oregon ecotyping. The production figures were considered baseline production and were applied to analysis areas as background forage. Changes from baseline production levels due to vegetation manipulation were estimated. Yields were modeled to depict production after thinning, clearcut, shelterwood, or extended shelterwood silvicultural treatments.

Allowable utilization of forage by slope and soil hazard class was established. The percent utilization allowed was proportioned between wildlife and livestock based on the emphasis in a given management strategy. Some resource mitigation is reflected in the percent utilization allowed for other environmental factors such as scenery and recreation settings. In addition, the allowable utilization reflects needs for soil and watershed protection, as well as individual plant requirements. Yields produced through the analysis were measured in animal unit months (AUM's) for both wildlife and livestock.

A detailed description of the establishment of forage yields are contained in a March 29, 1985, memo to the Planning Team leader, subject 1920 (20-1), "Range Coefficients."

3. Timber Yields

An Interdisciplinary Team which included wildlife and fisheries biologists, landscape architects, soil scientists, hydrologists, economists, silviculturalists, and timber management personnel at the Ranger District, Forest, and Regional Office levels were involved in the process. The yield tables were reviewed at several points.

Yield coefficients were developed for each management prescription and analysis area combination which permitted regulated timber harvest. This involved the development of both empirical yield tables for existing mature, immature one-storied, and immature two-storied timber stands and managed yield tables for seedling/sapling stands and future stands created by harvesting existing stands. Each of these yield coefficient categories will be discussed separately in the following sections.

Prior to prescriptions being loaded into FORPLAN, economic analysis of timber prescription feasibility and efficiencies, (Stage II economic analysis) was done by Joan (Krzak) Zieglertrum, the Forest economist at that time. This analysis disclosed that it was uneconomical to reforest non-stocked lands. It also concluded that all analysis areas that were to be used for FORPLAN modeling that contained merchantable volume were economical to harvest and reforest.

After making the first trial FORPLAN runs, it became apparent that the yield table did not precommercially thin but attempted to commercial thin, which was not economical. At this point, that table (GF-2) was dropped from future consideration.

a. Timber Yield Coefficients for Existing Timber Stands

Volume projection for existing stands is very important because predicted yields are critical in the determination of allowable sale quantity. Allowable sale quantity (ASQ) is the quantity of timber that may be sold from the area of suitable land covered by the Forest Plan for a time period specified by the Plan. These yields, when stratified by specific silvicultural regimes are termed "empirical yields." Volumes were calculated in cubic feet. The associated cubic foot yield coefficients were entered into the relevant yield tables in the FORPLAN yield file. The cubic foot outputs were converted by FORPLAN to Scribner Decimal C board foot measurements based on vegetative type and diameter class specific conversion ratios. Harvest schedules were based on cubic foot measurements.

This section summarizes the empirical yield table estimation process. Additional details can be found in the forest planning document titled "Timber Yield Table Documentation", dated February 1985.

Empirical yield tables were computed by John Teply in the Regional Office using 1977 timber inventory data. Data was stratified according to Forest biological model components and yields were computed using a method developed by John Teply (J. L. Teply. October 6, 1976. Rough Draft: The Development and Projection of Standing Yield Tables, Region 6). Copies of Teply's rough draft, the biological model matrix showing inventory plot distribution, and the basic empirical tables are included in Jim Opdycke's 1920 (26-2) memo titled "Timber Yield Tables for Existing Stands", dated October 7, 1981.

The basic tables were reviewed by the Timber Management Planner and the Forest Silviculturist for reasonableness as suggested in Teply's paper. Projected basal areas, cubic foot volumes and rates of growth were compared with Technical Bulletins 201 (Douglas-fir) and 630 (ponderosa pine), P. H. Cochran's PNW 263 (Eastside Douglas-fir and white or grand fir), and local plot data. All tables except number 0301 were found to be reasonable.

A table was not produced for two-story stands with seedling and sapling understory in Model Group II (moist sites) because there were only two inventory plots in this component. These stands were combined with the two-story with the poles component of Group II (table 0402).

There was difficulty in developing regressions for the two-story/seedling and sapling understory in Group I (dry sites). The resulting table (0301) was found to be unsatisfactory because of an unaccounted for decline in growth in the early future decades. The Forest Silviculturist and Timber Management Planner examined stand exams and plot data and with phone consultations with John Teply, R6 Biometrician, decided to combine this component with the two story/poles. The examined data showed very little difference in understory sizes, plus there were only nine inventory plots in the seedling and sapling strata.

A combined table (0301-0401) was created. Upon examination, this table was found to be satisfactory for the first nine future decades. From the tenth decade on, the rate of volume decline was far too rapid and did not appear to be biologically sound. Jim Odycke, the Timber Management Planner, discussed this problem by phone with John Teply on September 1, 1981. It was decided that the problem was probably due to either a lack of plot data for a critical period, a few plots with extremely low volume, or both. Teply recommended that the table be adjusted by using the rate of decline of table 0402 for a similar period. This was done. The adjustment worksheet is included in Opdycke's October 7, 1981 memo on file in the Wenatchee National Forest Supervisor's Office.

Harvest projections for the No Change Alternative were developed using the Stand Table Projection Method. Briefly, this method involves the following steps.

1. The existing stand structure was developed and summarized from 1961 and 1968 inventory statistics. Stands are listed according to age and standing volume.
2. Growth and mortality rates were calculated for existing stands based upon measured plot data
3. Growth and mortality rates for future stands were projected from using normal yield table data.
4. Present and predicted future stand tables were developed by applying appropriate growth and mortality rates to the existing stand structures.
5. Periodic stand yields were estimated as the difference between the yield of existing stands and future stands under management.

Yields were adjusted in some instances where modified harvest practices were required to meet management objectives for maintaining visually appealing landscapes.

More specific details relating to the two different working circle methods are found in the allowable cut calculation descriptions in the Timber Management Plans.

(1) Basic Empirical Volumes

The empirical base tables represent all the net volume in trees, 9 inches DBH or larger, measured in the 1977 inventory. This volume does not differentiate by maturity of the trees or by their position in the stand. In two-story stands there is a need to separate residual overstory and excess tree volume from future crop tree volume and to establish crop tree age. In immature pole and small sawlog stands, the available excess tree volume has to be identified and an equivalent crop tree age established for application of managed yield tables. In addition, disease, insect, and logging damage have to be dealt with in both cases.

In consulting with Regional Timber Planners, we found there is no established method to develop empirical yield tables for existing two-story and immature stands. The Forest Timber Management Planner and Silviculturist therefore developed the process discussed in the following sections.

(a) Single-Story Mature Stands

Basic empirical volumes are used as originally computed. The first entry in these stands will be a regeneration harvest.

(b) Two-Story Stands

It appears as though, based on examination of inventory plots and timber stand examinations, the computed empirical volume includes all trees, 9 inches DBH and greater, in both overstory and understory. Analysis of timber stand examinations further indicates that understory in some stands is inadequate for further management because of low stocking, dwarf mistletoe, or severe insect damage. In addition, the overstory in some stands is so heavy most of the understory would be destroyed during removal of the overstory. These stands would require regeneration harvest on their first entry.

The Forest Silviculturist analyzed timber stand examinations taken during the 1977 inventory and determined what proportion of the stands should be regenerated without saving the understory for further management. This was done by considering the interrelationships of heavy overstory volume per acre (usually 25 MBF+), growth rate of crop trees, dwarf mistletoe, spruce budworm, and lack of sufficient stocking in the understory. Stands with more than 50 percent of the timber stand examination plots needing regeneration were classified as such in their entirety. The regeneration ratio was calculated as a percent of the total number of stands in the particular biological model component. Basic empirical volumes as computed by Teply are applicable to these stands.

The understory in other stands indicates a reasonably good expression of crop tree dominance. The understory in these stands is manageable as future crop trees. This may be due in part to differences in actual ages and species mixture. Level of crop tree stocking, equivalent crop tree age, and probable crop tree loss in the overstory removal operation must be estimated. The volume of merchantable understory excess trees which could be removed along with the overstory must also be determined. In addition, a point must be established at which overstory removal and further management of the understory will no longer be considered. This is done to allow for the prolonged effects of overstory suppression if not removed in a reasonable time.

The proportion of empirical volume available for harvest at first entry in stands suitable for understory management consists of overstory volume, merchantable excess understory volume, and merchantable crop trees lost in logging. Overstory and understory volume available is determined from stand exams

Crop tree loss during final overstory removal is commonly experienced on the Forest but we have no measured data. J. W. Barrett made and published a case study (PNW-273, 7/76) addressing a similar problem in ponderosa pine. He found that on an average in his study area, 20 percent of the crop trees on 75 percent of the area (25 percent not stocked) were lost in overstory removal. In the judgment of the Forest Silviculturist, this figure is also applicable to our conditions and is the best information available at this time. The first entry leave volume is reduced by 20 percent and this amount is added to the cut volume in anticipation of required removal of damaged merchantable trees.

It is necessary to determine effective crop tree age and stocking in order to estimate growth after the first entry. The Silviculturist used a combination of understory age, crop tree DBH, excess tree DBH and volume in comparison with the high intensity managed yield tables to establish stand characteristics between first entry and regeneration harvest. The crop tree stocking ratio was also estimated from the timber stand examinations. This allows for unstockable voids and lack of understory stocking due to overstory clumps, disease, etc. Losses from logging are also included.

Stands were only considered for further management of the understory for the first three decades. At this point, the average empirical age will have reached or exceeded the culmination of mean annual increment of managed stands, much of the understory will be of merchantable size (7 inches DBH), and the prolonged effect of overstory competition will have slowed understory growth to the point where regeneration is more feasible than management of the understory.

(c) Single-Story Immature Stands

Computed empirical volume for stands mapped as immature poles or small sawlogs is made up of crop tree volume, excess tree volume, and volume from unmapped mature sawlog inclusions. An analysis of inventory plots and timber stand examinations indicates that a portion of this type is not adequately stocked for further management and should be regenerated at the first entry.

The same general premises used in two-storied stands, for determination of regeneration needs and adaptation to management, were used here. One basic difference is the assumption used for determining the first entry volume for the further management stands. In this case, the proportion of the existing volume to be removed is considered to be similar to a commercial thinning instead of a combined overstory removal and thinning. Adjustments in gross yields are for crop tree stocking and estimated defect. No significant logging damage is anticipated in the first entry because of the size of the trees and the nature of the harvest.

Considering the average empirical age, these stands will be available for management of the understory for the first three decades only. The same basic rationale used for two-storied stands applies.

b. Timber Yield Coefficients for Managed Stands

“Managed yield tables” are built to reflect regeneration (natural or planted) after harvest, precommercial thinning when appropriate and early suppression of competing vegetation. No such stands exist that have been under such management throughout an entire rotation in eastern Oregon and Washington (P. H. Cochran 1979). Therefore, to predict growth of newly established stands, many assumptions must be made. These assumptions are derived from measurements of existing stands, research findings from other areas, and broad-based yield tables.

The purpose of managed yield tables is to estimate the standing inventory of wood fiber on existing plantations and future managed stands, and to predict how it would grow according to weighted average site conditions and alternative silvicultural regimes. Yield tables were developed for all management prescriptions which permit regulated timber harvest. They were calculated in cubic feet. This section summarizes the managed yield table development process. A more in-depth discussion can be found in a 1920 memo titled "Stand Prognosis Adjustment-Development of Managed Yield Tables, dated February 7, 1984."

For planning purposes, the timber inventory of the Wenatchee National Forest was categorized into two vegetative types, wet forest and dry forest.

A National group of experts studied the timber yield tables used for Forest planning during 1983. As a result of the group's findings it was decided to update Wenatchee National Forest's managed timber yield tables for regenerated stands by using the latest version of Prognosis.

On July 19, 1983, Ralph Johnson, Mensurationist assigned to State and Private Forestry in Missoula, Walt Knapp, Region 6 Yield Table Specialist, and Jim Opdycke, Timber Planner for the Okanogan and Wenatchee National Forests, met in the Regional Office to map out a process. The basic process was to: (1) establish a young stand data base individually for the wet forest and dry forest vegetation type, (2) predict the growth of the young stands using Prognosis and (3) calibrate Prognosis to reasonably fit known Forest data.

Documentation of Prognosis is in General Technical Report INT-133, "User's Guide to the Stand Prognosis Model", William R. Wykoff, Nicholas L. Crookston and Albert R. Stage, Intermountain Forest and Range Experiment Station, Ogden, Utah, September 1983.

The 1977 Continuous Forest Inventory (CFI) was used as a data source. The 1977 CFI computer file was screened for relatively even-aged plots using a computer routine developed by Ralph Johnson. The selection of plots from this inventory was not intended to provide a statistical sample, but rather to establish some actual data for use as a ground identified base from which to make Prognosis growth predictions for regenerated stands. The following plots were used in prognosis to develop all managed timber yield tables.

<u>Vegetative Type</u>	<u>1977 CFI Plot #</u>
Dry Forest	286
	459
	462
	607
Wet Forest	284
	1424

The following is the basic data used to develop managed timber yield tables for tentatively suitable timber lands.

DETAIL COMMON TO ALL PROGNOSIS RUNS:

<u>KEYWORD</u>	<u>GRP I (DRY)</u>				<u>GRP II (WET)</u>	
BAMAX	183				313	
HABITAT CODE	260				260	
VERSION	16				16	
NUMCYCLE	26				26	
PLOTS	286,459,462,607 ^{1/}				284,1424 ^{1/}	
INVYEAR	5	5	5	27	5	7
TIMEINT	+5	+5	+5	+1	+5	+3
TIMEINT	+10	+10	+10	+1	+10	+10
TIMEINT	+10	+10	+10	+1	+10	+10
	30	30	30	30	30	30 ^{2/}

^{1/} Species composition of plots 286, 459, 284, and 1424 was adjusted to represent Forest average conditions.

^{2/} The average age of the selected base plots were converged to a common age of 30 by making cycle length adjustments in the first three cycles in Prognosis

The selected plots were entered individually in Prognosis. Variant 16 with species habitat 260, was used as recommended by Johnson. Region 6 Variant 16 contains both cubic feet and board feet volume formulas but only cubic output was used. Variant 16 has been calibrated to North Central Washington even though no habitat types have been identified in North Central Washington at this time.

Prompt reforestation is the objective on the Wenatchee. The primary site preparation tool on many sites is YUM yarding, so there is no need for delay between harvest and planting. In addition, many sites have at least partial stocking of natural or residual seedlings or saplings after logging. On these sites there may be a slight minus regeneration lag. For these reasons, the Wenatchee doesn't show a regeneration lag when using the prognosis generated yield tables calling for planting.

A four year regeneration lag is used in yield tables calling for natural regeneration. Seed production of the principle species, especially ponderosa pine and Douglas-fir, is very unpredictable. The last large seed crop in ponderosa pine was 1971. The last good Douglas-fir crop was 1978. A poor crop is predicted again in 1984 for both species. Therefore, we think the four year total difference between regeneration by planting and waiting for natural regeneration, considering the cyclic nature of seed crops, is reasonable.

Several of the plots used for the basis tables were in areas of natural lodgepole regeneration. With low to moderate investment levels these stands would remain in lodgepole pine through the rotation. On plots where planting and precommercial thinning are proposed, Douglas-fir will be planted and a species preference against lodgepole pine will be used at commercial thinning entries.

On wet ecotypes, mortality rates for thinned plantations is historically low. Because adequate moisture is available, mortality rates are expected to be only 50 percent of the default level in Prognosis if competition is controlled. This would approximate the mortality rate found for Douglas-fir at a 12-foot spacing (Reukena, 1979).

In order to adjust the base age of the Prognosis tree lists to DBH age, 10 years were added. This is the average time found to get trees to a 4.5 foot height where the age for inventory plots was measured

The individual Prognosis predictions were run under the sums-to-date option which stores separate results and produces combined summary tables. A number of comparisons were then made to determine the reasonableness of the results.

The Prognosis analysis process was done by Monte Bickford, Forest Silviculturist, Bob Pederson, LMP Analyst, and Jim Opdycke. The height/DBH relationships for the various growth projections of the young stands compared very favorably with older stands.

All regenerated stand timber yield tables must be adjusted from the Prognosis predictions of gross volumes to net volumes. This is because Prognosis doesn't account for factors such as defect and break-age, less than 100 percent stocking, or greater growth of genetically superior planting stock.

Existing stand (empirical) timber yield tables for roaded analysis areas must be adjusted to account for a reduction in stocking due to roads. This is due to the design of the survey used to develop the empirical tables. Any plots which would have contained roads were relocated. Arterial and collector roads are coded in R2MAP. The acreage they encompass will be removed from the tentatively suitable timber lands during the analysis area sort process in R2MAP. Existing stand timber yield tables are reduced by a factor reflecting the average area of existing local roads

No adjustments are made to the existing tables for new local roads (i.e., additional roads in the roaded analysis areas and all roads constructed in the unroaded analysis areas). This assumes that trees removed for road rights-of-way are utilized. The regenerated stands on all analysis areas are adjusted to reflect the reduction in stocking due to these roads.

Tables B-III-2, B-III-3, and B-III-4 display the adjustments used to revise the appropriate yield tables developed using Prognosis.

**TABLE B-III-2
TIMBER YIELD TABLE ADJUSTMENTS**

Table	Ecotype	Defect and Breakage	Non-stocked Other Than Roads	Non-stocked Roads	Genetics	Total
Unroaded,existing Mature & Immature	Dry	0	0	0	0	0
	Wet	0	0	0	0	0
Unroaded,existing GF-1	Dry	-4.0	-4.0	0	+7.7	-0.3

* Defect increased 1 percent for trees left to 260 years.

**Defect and breakage increased 3 percent due to no intermediate harvest to salvage blowdown and mortality.

4. Sediment Yields

Sediment yield estimates were developed as part of the information used to determine the relative risk between alternatives. The Modified Universal Soil Loss Equation (MUSLE) was used as the basic process for determining soil losses. The Soil Resource Inventories for the Wenatchee National Forest (1976) and for the Snoqualmie National Forest-Eastside (1973) provided most of the basic data used in the sediment modeling process.

Sediment delivery factors were developed using percentages provided by the Intermountain Forest and Range Experiment Station located at Boise, Idaho. Background erosion rates (natural erosion from the forest without man's activities), were developed using data from published studies, in combination with local soil resource inventory information. Erosion rates were also developed for those management activities having the greatest potential for accelerated sedimentation (timber harvest activities and associated road construction).

A modeling process was developed to estimate both background and management induced sediment production, by alternative, within FORPLAN. Using the five biologic zone groupings in the forest planning process as a base, a fourteen step process was developed to estimate background and management activity sediment yields. Background sediment yield was obtained directly from FORPLAN. Basic output on management activity delivered sediment was obtained from FORPLAN and adjusted to reflect that most of the new road development on the Forest would be completed within the first three decades

This systematic approach was used to develop estimates of increased sediment yield from management activities in order to indicate trends and to compare alternatives. These model outputs do not represent absolute quantities of sediment. Natural systems are simply too complex for completely accurate predictions given our present state of knowledge. This modeling effort was just one of the tools that the Forest used in the analysis leading to a reasoned choice among alternatives.

Additional information on the sediment modeling process may be found in the planning records on file in the Supervisor's Office, Wenatchee National Forest.

5. Water Yields

The natural water production, or background water yield, was not analyzed in FORPLAN, but was developed by using experienced water yield data. The existing water yields were reduced to reflect the existing manipulated vegetation through man's activities, primarily timber harvest.

The basis for increased water yield due to vegetative manipulation was primarily from a series of reports prepared in 1974 by Washington State University and the University of Washington. The report titled "Model Development and System Analysis of the Yakima Basin" provided the data base.

The water yield increases are based on vegetation manipulation by silvicultural prescriptions only, and are directly proportional to the amount of vegetation removed. The water yield recovery assumed that reforestation would be achieved within a five-year period after timber harvest.

Additional formation on the water yield modeling process may be found in the Planning records and the document entitled "Coefficient Documentation for Water Yield Increases" (#2 Rough Drafts 1920, 11/9/81, Gran Rhodus).

6. Local Road Construction

Local road densities were developed from fiscal year 1980 and 1981 timber sale data. Average skidding distances were calculated for each logging method used in the timber sale, and used to model logging settings. Gentle slopes were modeled for 100 percent tractor logging, while moderate slopes were modeled for 75 percent skyline and 25 percent highlead settings. Steep slopes were modeled at 58 percent longspan skyline and 42 percent helicopter settings. The setting widths determined road spacing. Road spacing for the model settings was expanded to determine road density per section (640 acres) of land and per acre. Road construction was assumed to occur at these densities in currently unroaded areas during the first entry for timber harvesting. Currently roaded areas were assumed to need additional road construction to reach these densities during the first entry during the modeling horizon for timber harvesting. Twenty-five percent of the roads were assumed to need reconstruction during the first entry in currently roaded areas and subsequent entries in all areas.

Arterial and collector road outputs were analyzed outside of FORPLAN and were based on a transportation plan by alternative.

More detail on procedure for local roads can be found in a September 22, 1981, memo, subject 1920, "WNF FORPLAN Road Density Analysis" by John Malone.

7. Anadromous Fish

Anadromous fish outputs and smolt habitat capability were estimated using coefficients outlined in the April 22, 1987 letter to Regional Foresters, Regions 1,4,6 titled "Anadromous Fish Planning Coefficients". Coefficients outlined in this letter were used along with information obtained from other agencies to generate current and potential smolt habitat capability and associated outputs.

Increases in smolt production were based upon assumptions for adult returns, success of management prescriptions in maintaining habitat, and success of the habitat improvement program. A more detailed description is contained in a document by Ken MacDonald, titled "Documentation for the Formulation of Fisheries Outputs for the Wenatchee Forest Plan".

IV. ECONOMIC EFFICIENCY ANALYSIS

This section describes the costs and benefits, as well as some concepts, involved in economic efficiency analysis, how they were derived, and how they were used in the Forest Planning process. Economic efficiency analysis is required by the National Forest Management Act Regulations (36 CFR 219) and played an important role in the development and evaluation of Forest Planning benchmarks and alternatives. Specifically, the Regulations (36 CFR 219.12(f)) state that:

“The primary goal in formulating alternatives, besides complying with NEPA procedures, is to provide an adequate basis for identifying the alternative that comes nearest to maximizing net public benefits.”

They follow up in 36 CFR 219.12(f)(8) by stating that:

“Each alternative shall represent to the extent practicable the most cost efficient combination of management prescriptions examined that can meet the objectives established in the alternative.”

The requirements of 36 CFR 219.12(f) may not be met by Alternative NC. It is not possible to evaluate the present net value of this alternative. Evaluation of non-priced benefits and costs may require use of different methods than for other alternatives.

A. Descriptions of Some Concepts Related to Efficiency Analysis

Before we get into the specifics of how economic efficiency analysis was used in the development of the FEIS and Forest Plan, a few concepts and terms related to efficiency analysis in general need to be explained.

1. Priced Outputs

Priced outputs are those that are, or can be, exchanged in the market place. The dollar values for these outputs fall into one of two categories: market or nonmarket (assigned). The market values constitute the unit price of an output normally exchanged in a market, and are expressed in terms of what people are willing to pay as evidenced by actual sales transactions. Nonmarket values constitute the unit price of an output not normally exchanged in a market and must be estimated by using some comparable sales transaction data in combination with various theoretical techniques. They are valued in terms of what reasonable people would be willing to pay (above participation costs) rather than go without the output.

Priced outputs with market values include timber, firewood, and non-recreation special uses. Priced outputs with nonmarket values include recreation, wildlife and fish, and range.

Timber values are expressed in terms of dollars per thousand cubic feet (MCF) paid by purchasers at the time of harvest. They are based upon transactions which occurred on the Wenatchee National Forest. Prices were developed for key individual species sold on the Forest. Prices vary by tree size as well as by species.

Firewood and non-recreation special uses are valued in terms of fees actually paid for these goods and services on the Forest. Permit fees are also charged for other goods and services such as grazing, camping, summer homes, and ski areas. These outputs have nonmarket values developed for them that are considered better estimates of their actual value. Permit fees are not included in benefit calculations for these outputs to avoid double-counting.

Forest-based recreation is not normally bought and sold in the market place. The values for recreation are based upon the 1985 RPA Program, and were ultimately determined by examining comparable market transaction data in conjunction with some theoretical estimation techniques. The values are expressed in terms of dollars per recreation visitor day (RVD), and were specific to different types and qualities of recreation activities that may be experienced on the Forest.

Range outputs represent the amount of forage permitted to be grazed and are measured in terms of animal unit months (AUMs). While the Forest receives grazing permit fees, the value received for the AUMs is not based on market transactions. Therefore, the dollar values per AUM used in the analysis of the benchmarks and alternatives were market price estimations based on the contribution of National Forest grazing to the net income of ranchers.

Priced outputs do not include minerals. Substantial mineral resources are known to exist on the Forest, but the timing of their development and the quantities that will be extracted are highly speculative. Variation in mineral benefits could possibly occur among alternatives, however. Water is also not priced in this analysis. The Forest contributes a great deal of water to the "water short" area of eastern Washington. Increases in water yield above naturally occurring levels vary between alternatives but their benefits were not quantified.

2. Nonpriced Outputs

Nonpriced outputs are those for which there is no available market transaction evidence and no reasonable basis for estimating a dollar value commensurate with the market values associated with the priced outputs. Subjective non-dollar values must be attributed to the production of these outputs.

Present net value is used to compare alternatives with regard to their output levels for priced resources, and their efficiency in producing them. However, the production of nonpriced outputs also influences the decision making process. The importance of the need to consider these subjectively valued benefits is addressed in the NFMA Regulations which charge the Forest Service with identifying the alternative which comes nearest to maximizing net public benefits (36 CFR 219.12(f)). Net public benefits (NPB) include both priced and nonpriced resource outputs, less all costs associated with managing the area. As stated earlier, all priced outputs and all costs associated with managing the Forest are included in the calculation of present net value. To this, the net subjective values of the nonpriced outputs must be added in order to arrive at the overall net public benefit of an alternative.

In some cases, the importance of providing nonpriced benefits can outweigh the advantages of producing higher levels of priced outputs. The provision for many of the nonpriced benefits is achieved by applying constraints to the production of priced outputs (i.e., such as timber harvesting constraints in FORPLAN). These constraints usually result in a decrease in PNV based upon the priced outputs. Subjective judgments are then necessary in assessing whether the benefits of producing the nonpriced outputs exceed the opportunity costs associated with producing fewer priced outputs. If a PNV tradeoff induced by the provision of a nonpriced output is judged acceptable, then a positive contribution to net public benefit has resulted, and the alternative is more efficient overall.

The nonpriced outputs considered during the development and evaluation of alternatives are discussed below. These are outputs and effects which are influenced to a large degree by decisions regarding how to manage the Forest. They are the topic of one or more issues and concerns which were identified at the outset of the planning process. While the quantitative dollar values of each cannot be determined, they can generally be evaluated by examining such quantitative indicators as acres of appropriate allocations, resource inventories, or timber production related activities and outputs. Some of the most important nonpriced outputs and effects addressed during the Wenatchee National Forest planning process revolve around maintaining or enhancing the following:

Water Quality and Quantity - A number of cities and towns near the Forest use water coming from the Wenatchee National Forest for domestic purposes. This use is expected to increase in the future as the area's population increases. The demand for sediment-free irrigation water is increasing as new lands are cultivated. The quantity of water flowing off the Forest is affected somewhat by vegetative manipulation on the Forest. Water quality is also affected by vegetative manipulation and road construction.

Wildlife Habitat and Diversity - The Forest sustains a wide variety of fish and wildlife species because of its variety of habitats. Activities which affect habitat can have a direct influence on fish and wildlife. Timber harvesting, recreation, livestock grazing, road management and fire management can affect wildlife habitat. Small hydroelectric projects and irrigation impoundments can affect fish habitat. Water quality also greatly affects fish habitat. Recreational use of wildlife and fish, and commercial harvest of anadromous fish, are priced outputs. The issue of wildlife habitat and diversity is broader than what is represented by the priced outputs. The manner in which alternatives maintain wildlife habitat and diversity is reflected as a nonpriced component of net public benefit.

Visual Quality - The Forest is well known for its variety of scenery and natural appearing environment. About 13 percent of the recreational use on the Forest is driving for pleasure and viewing scenery. The quality of most other types of recreational use is also strongly affected by the scenic quality of the recreational setting. The visual quality of alternatives has been quantified in terms of the number of acres meeting various visual quality objectives. Visual quality is also strongly correlated to estimates of each alternatives capacity to provide various types of recreational experiences.

Minerals and Energy Resources - Interest in mineral resources on the Forest has been high since a major gold discovery took place in March 1983. There is also continuing interest in energy resources. More than one-fourth of the Forest had existing or pending oil and gas leases as of February 1985. Recreational mining also takes place on the Forest. The alternatives will be ranked according to their mineral potential and accessibility.

Cultural Resources - There is an ongoing program to identify and evaluate historic and prehistoric cultural resources. Over 500 cultural resource sites have been identified to date within, or adjacent to, the Forest. These sites represent a broad cross-section of uses, spanning a period of several thousand years. Possible loss or degradation of these sites increases with land modifying activities and increased public use of the Forest.

3. Discounting

Financial analyses of alternative investment options usually involve cash flows over different periods of time in the future. Inherently, there is a time value associated with money. Due to man's propensity to consume now, a dollar today is worth more than a dollar ten years from now. Discounting is a process for adjusting the dollar values of costs and benefits which occur at different periods in the future to dollar values for a common time period so that they may be compared. Usually the common time period is the present, in which case, the discounted cash flow is referred to as the present value. The primary discount rate used for the PNV calculations was four percent. An alternate rate of 7 1/8 percent was also used to evaluate the sensitivity of the results to higher discount rates.

4. Present Net Value

Present net value (PNV), on the other hand, is a dollar measure of economic efficiency. It was the quantitative criterion used to help ensure that each alternative consisted of the most economically efficient combination of priced outputs and management activities needed to meet the objectives of the alternatives. Present net value is the difference between the discounted value of all priced outputs (benefits) less all costs associated with managing the planning area, regardless of whether they were incurred for the production of priced outputs, nonpriced outputs, or overhead expenses for general maintenance of the organization. Therefore, PNV is an estimate of the current value of the priced Forest resources after all costs of producing both priced and nonpriced outputs and meeting other multiple-use objectives have been considered.

5. Opportunity Costs

Opportunity costs are defined as the value of a resource's foregone net benefit in its most economically efficient alternative use (FSM 1970.5). In relation to the economic analysis performed for Forest Planning, it represents the decrease in PNV of an alternative or benchmark when some alternative level of resource outputs are forced into solution. Therefore, opportunity costs measure the change in PNV for priced resource outputs, and can be used to measure the relative value traded off in order to produce the nonpriced benefits included in net public benefits.

6. Net Public Benefits

The maximization of net public benefits is a goal of the Forest Planning process. Net public benefits is the overall value to the nation of all outputs and positive effects (benefits) less all inputs and negative effects (costs), whether they can be quantitatively valued or not. Conceptually, net public benefits is the sum of the present net value of priced outputs plus the net value of all nonpriced outputs. Net public benefits are maximized by the alternative which has the greatest excess of priced and nonpriced benefits over costs. A major objective of the Forest Planning process is to provide information that helps determine which alternative provides the mix of outputs and effects that best responds to the ICO's while maximizing the net public benefit of managing the National Forest. Net public benefits cannot be expressed as a numeric quantity because it includes the qualitatively valued nonpriced outputs. Therefore, identifying the alternative which maximizes net public benefits is a subjective decision.

7. Net Cash Flow

Cash payments are actually received for some Forest outputs such as timber, livestock forage, camping at some developed sites, mineral leases, and special uses. These payments represent a return to the U.S. Treasury as opposed to other benefits, such as those for dispersed recreation, which represent a value to society in general. Cash payments can be contrasted to the Forest Service budget to examine net cash flows to the U.S. Treasury.

8. Welfare Distribution Effects and Impacts

There is another level of effects which is also a concern of National Forest Policy and Management. These are the welfare distribution effects influenced by the mix and level of outputs produced by the National Forest. They can be either positive or negative. Their impacts can also be local, regional, or national in scope. Some distributive effects such as changes in consumer prices or taxpayer costs have

national level impacts. Others, such as induced jobs and income, or payments in lieu of taxes are more local or regional in nature. They are more related to questions of equity (i.e., who pays and who benefits) rather than efficiency. They are not assessed in the context of the efficiency criteria associated with the PNV and net public benefit concepts. However, these positive and negative distributive effects need to be assessed in conjunction with the net public benefit measures, since equity objectives often influence efficiency objectives and vice versa. These will be discussed in more detail in Section V of this appendix.

B. Parameters and Assumptions Used For Economic Efficiency Analysis

In order to calculate the present net value for each alternative, several assumptions had to be made regarding discount rates, demand curves, real dollar adjustments, and real price and cost trends. This section will summarize these decisions and their resulting parameters. A more detailed discussion can be found in various process records in the Supervisor's Office.

1. Discount Rates

Discounting requires the use of a discount rate, an interest rate that represents the cost or time value of money, in determining the present value of future costs and benefits. Two discount rates were used to calculate the present net values for each benchmark and alternative. Both of them were real discount rates meaning that they were adjusted to exclude the effects of inflation (Real dollar adjustments will be discussed more below). According to FSM 1971.71:

For evaluations of long-term investments and operation in land and resource management in the 1980-1985 planning period, a four percent real discount rate shall be used. Evaluations should also discount benefits and costs at the real discount rate used in the most recent RPA to determine sensitivity of alternatives to variations in the discount rate.

The four percent rate approximates the "real" return on corporate long-range investments above the rate of inflation (Row and others 1981). The four percent rate was used to solve FORPLAN and calculate the PNV for each benchmark and alternative. The 1985 RPA program used a real discount rate of 7-1/8 percent. An analysis of the sensitivity of the Preferred Alternative to the discount rate was performed by solving FORPLAN using both the four percent and the 7-1/8 percent discount rates. For all other benchmarks and alternatives, the present net values were merely recalculated using this second discount rate (FSM 1971.71). Finally, all costs and benefits were discounted from the midpoint of the decade in which they were incurred.

2. Demand Curves and Real Price Trends

As specified by the Washington Office (1920 letter to Regional Forester, "Downward Sloping Demand curves", 2/3/81) and in keeping with FSM 1971.65, horizontal demand curves for timber and nontimber resources were used to analyze the benchmarks and alternatives for the FEIS. Many factors can influence the demand for stumpage from any one Forest (Adams and Haynes 1985). Some of these factors include trends in (1) interest rates, (2) the species and products mix of forest products consumption, (3) use of wood for energy, (4) forest products exports, (5) the cost of wood in Canada, (6) the rate of technical improvements in wood and fiber processing, and (7) the levels of other National Forests harvests. All of these contain some degree of uncertainty regarding their future states. Neither the empirical nor the theoretical bases have been well enough developed to derive reasonable estimates of the demand functions for the resources offered at the Forest level. Evidence does exist, however, that suggests that the elasticity in the the portion of the timber demand curve for which the Forest can

influence output levels is such that prices would be relatively insensitive to some “reasonable” range of quantity offerings. In other words, it appears that the timber demand curve for the range of output levels analyzed during the development of alternatives is nearly horizontal.

Real price trends were developed and used to represent the rate at which resource values will change over time as a result of anticipated supply and demand interactions in the market place. As specified by the Regional Office (1920 letter to Forest Supervisors, “Timber Price Trends, Values, and Costs”, 9/15/84), a one percent per year real price trend for stumpage was used for FORPLAN harvest scheduling analysis. These were applied for the first 50 years, and then a zero percent price trend was assumed for the remaining 100 years of the harvest scheduling planning horizon. These imply that nominal stumpage prices (i.e., those which include the effects of inflation) will increase during the next 50 years at a rate of one percent greater than the general rate of inflation, and equal to the general rate of inflation after that.

Since price trends are reflections of expected futures, there is an inherent uncertainty involved with making such projections. In recognition of this uncertainty, we performed a sensitivity analysis by rerunning RUN #3 of the benchmarks using alternative stumpage price trends of zero, two, and three percent. The results of these runs are quite complex and are discussed in detail in the Forest Planning Document titled “Analysis of the Management Situation.” Generally, higher price trends make silvicultural investments economically more attractive, but they also tend to delay timber harvest until later decades.

Based on Washington Office direction, a zero percent real price trend for all other resources was used during the development of the benchmarks and the alternatives. In other words, their future nominal values will change at rates equal to inflation.

3. Real Cost Trends

Based on Washington Office direction, zero percent real cost trends were used for all future costs used in the development of the benchmarks and alternatives. In other words, the costs of labor, fuels, materials, and all other factors of production involved with managing the Forest are assumed to change at a rate equal to the rate of inflation.

4. Real Dollar Adjustments

Future prices and costs can be expressed in both nominal and real terms. The projection of nominal values includes the effects of inflation on these values. The projection of real values does not. For example, assume that the future prices for a commodity are projected to increase annually by eight percent. Also assume that the rate of inflation is anticipated to be five percent. In real terms, the prices are increasing by only three percent per year above and beyond the rate of inflation. Real value changes are the result of the interactions of supply and demand forces in the market place. They do not include the effects of inflation.

All future values and costs used in the Forest Planning process were expressed in real 1982 dollars, consistent with the 1985 RPA program. The GNP implicit price deflator index was used to convert both historical and future nominal prices and costs to this common base (FSM 1971.32b).

C. Costs Considered for Economic Efficiency Analysis

The cost of an alternative or benchmark is the sum of the costs of implementing the various mixes of management prescriptions over the Forest plus additional fixed costs and overhead. The cost of implementing a management prescription is the sum of the costs of the activities (i.e., road construction, fence building, cultural resource inventory, etc.) which would occur. Many of these costs for a given activity vary depending on characteristics of the land or the overall goals of the management prescription. Costs for disposal of logging slash, for instance, are higher in prescriptions emphasizing visual quality in scenic corridors. Road construction is more expensive on steeper slopes.

Costs were identified by their Management Information Handbook (MIH) codes as described in FSH 1309.11a. Each cost was categorized as either fixed or variable. Costs were also categorized as either capital investments or operational and maintenance. For budget estimates, costs were further categorized according to the source of funding, whether appropriated from Congress or allocated from other sources.

Costs were estimated by the Interdisciplinary Team using historical data, projections made for the 1985 RPA, and contract estimates. Professional judgment was an important factor in assessing the relationship between historical costs and anticipated future costs. Costs were originally estimated in 1982. They were re-estimated in June 1984. Costs were reviewed by the appropriate staff officers.

1. Costs in FORPLAN

No fixed costs were included in FORPLAN. These costs do not vary by alternative or benchmark. Therefore they have no effect on model solution. All variable costs which were associated with activities modeled in FORPLAN were included in the model. Variable costs associated with timber management were directly included.

2. Costs Outside of FORPLAN

All overhead and fixed costs were handled outside of FORPLAN. Variable costs which did not relate to activities modeled in FORPLAN were also handled outside. Computer spreadsheets were used to estimate total present net value, discounted costs, and budgets. The spreadsheets included costs derived from FORPLAN runs as well as all other costs.

3. Real Cost Increases

Based on Washington Office direction, zero percent real cost increases were used for all future costs in both benchmarks and alternatives. In other words, all costs were assumed to change at a rate equal to the general rate of inflation.

4. Cost Summary

Table B-IV-1 summarizes Forest Service budget costs considered in economic efficiency analysis and calculation of budgets. Each cost item is summarized as to whether or not it is included in FORPLAN, varies significantly between alternatives, and is categorized as a capital investment or operations and maintenance cost. Items which are indicated as being both inside FORPLAN and outside FORPLAN, have only a portion of their cost in FORPLAN.

5. Logging Costs

The point of valuation for timber in economic efficiency analysis for the FEIS is before harvesting; in other words, as stumpage. However, logging costs cannot be ignored because they occur after the point of valuation. The value of stumpage (i.e., the price consumers would be willing to pay for the timber still standing on the stump) is indirectly influenced by how much it would cost to harvest it and transport it to the mill for further processing. Two identical logs would be worth the same amount when in the mill yard. If one log cost significantly more to deliver to the mill than the other (perhaps due to helicopter logging versus tractor logging), a timber purchaser would be willing to pay less for the unharvested tree. Therefore, stumpage values are a function of logging costs, as well as values of finished products derived from the logs.

The Wenatchee National Forest's FORPLAN model portrays timber mill values rather than stumpage values. Analysis area and prescription specific logging costs are also included. The net effect is to value timber as stumpage, with adjustments for analysis area characteristics and harvest methods.

Logging costs were developed by the Forest's Logging Engineer by making hypothetical timber sale appraisals. Cost estimates varied by slope class, harvest method, logging system, and average size of harvested trees. These factors were all portrayed in FORPLAN.

Logging costs were trended at the same rate as mill values. This adjustment was necessary to net out price trends applied to average logging costs included in the mill values. The net result is to have price trends apply to high bid stumpage.

D. Benefits Considered for Economic Efficiency Analysis

This section describes both the prices and nonpriced benefits which were incorporated in the economic efficiency analyses for each benchmark and alternative considered during the development of the FEIS.

Resource outputs to which dollar values were assigned constitute the priced benefits included in the present net value calculations. Like all of the costs included in the analyses, only those benefits incurred during the 50 year RPA planning horizon were incorporated in the PNV calculations. The economic efficiency analysis for each alternative also considered nonpriced benefits. These are outputs for which there is no available market transaction evidence and no reasonable basis for estimating a dollar value commensurate with the market values associated with the priced outputs. In these cases, a subjective qualitative value must be attributed to their production. Conceptually, the addition of the nonpriced benefits to PNV is used to derive the net public benefits associated with each alternative. Both priced and nonpriced outputs and their associated values are summarized below.

Priced outputs are those that are, or can be, exchanged in the market place. The dollar values for these outputs fall into one of two categories: market or nonmarket (assigned). The market values constitute the unit price of an output normally exchanged in a market, and are expressed in terms of what people are willing to pay as evidenced by actual sales transactions. Nonmarket values constitute the unit price of an output not normally exchanged in a market and must be estimated by using some comparable sales transaction data in combination with various theoretical techniques. They are valued in terms of what reasonable people would be willing to pay (above participation costs) rather than go without the output.

Benefits are based on the value of outputs on the production site. If off-site values are used for an output, all costs incurred and profits earned after the output leaves the site are deducted.

Priced outputs with market values include timber, firewood and non-recreation special uses. Priced outputs with nonmarket values include recreation, wildlife and fish, and range.

Nonpriced outputs are those for which there is no available market transaction evidence and no reasonable basis for estimating a dollar value commensurate with the market values associated with the priced outputs. Subjective non-dollar values must be attributed to the production of these outputs. Nonpriced outputs include such things as water quantity and quality, wildlife habitat, visual quality, minerals and energy resources, and cultural resources.

1. Benefits in FORPLAN

Timber, livestock forage, and unroaded dispersed recreation were valued in the FORPLAN model. Other benefits were added to these, after FORPLAN analysis in computer spreadsheet programs, to calculate total present net value. Outputs which were valued in FORPLAN are discussed below. Outputs which were valued outside of FORPLAN are discussed in the subsequent section. More detailed documentation of the specific values and the process used to develop them can be found at the Supervisor's Office.

Timber values were expressed in terms of dollars per thousand cubic feet (MCF) paid by purchasers at time of final harvest. Timber values were market prices based on transactions which occurred on the Forest. Values were developed for key tree species found on the Forest and by two inch diameter classes.

Timber stumpage prices were calculated based on prices paid for timber on the Wenatchee National Forest at the time of harvest during the period April 1977 through September 1983 (Hays and Barranco 1984). The source of this data was computer tapes from the Timber Sale Statement of Accounts. All prices were converted to constant 1982 dollars. Prices per thousand board feet (MBF) were developed by individual species by weight-averaging prices by the volume sold at that price.

Stumpage prices based on actual payments at time of harvest, as above, are sometimes referred to as "cut" values. "Sold" values, on the other hand, reflect the original bid price of the contract. The two sometimes vary due to escalation clauses in contracts which vary the price of timber through time. Cut values were used to maintain consistency with the 1985 RPA assumptions.

The stumpage values were converted from dollars per MBF to dollars per MCF using a conversion factor of 5.45 board feet per cubic foot. Average logging costs, determined from a statistical analysis of 2400-17 Timber Sale Report data for 1973 to 1982, were added to stumpage values to derive the value of timber delivered to the mill. Species specific values were then further refined by two inch diameter classes based on assumptions as to the average diameters of timber used in the stumpage valuation and price/diameter relationships developed by the Pacific Northwest Forest and Range Experiment Station. Timber values were expressed in FORPLAN as mill values by species by diameter class. These were tied to the two timber working groups in FORPLAN, dry forest and wet forest, by assumptions as to the species composition of each working group. Dry forest was assumed to consist of 40 percent Douglas-fir, 40 percent ponderosa pine, and 20 percent other coniferous species. Wet forest was assumed to consist of 34 percent Douglas-fir, 22 percent true firs, and 44 percent other coniferous species.

Site specific logging costs were developed as explained in Section IV.C.5 of this appendix. These costs were included in the FORPLAN model. The net effect of including mill values and logging costs in FORPLAN is to value the timber as stumpage. This point of valuation is consistent with that of other outputs included in the present net value calculations.

Table B-IV-2 below presents average working group stumpage prices by diameter class. These values are based on Forest-wide average logging costs and are shown here just as a frame of reference. Much more specific logging costs, reflecting analysis area and tree size characteristics, were used in the FORPLAN model. This resulted in a wide variation in stumpage values.

**TABLE B-IV-2
WORKING GROUP STUMPAGE VALUES (\$/MCF)**

<u>DBH Class</u>	<u>Dry Forest</u>	<u>Wet Forest</u>
7-9	150.48	222 44
9-11	225.51	287 36
11-13	300.53	329 65
13-15	363.27	399.85
15-17	419 86	447.49
17-19	471.59	490 98
19-21	514.61	525.50
21-23	558.89	555.87
23-25	587 34	577.98
25-27	604.75	595.96
27-29	619.61	604 95
29-31	634.46	613 94
31-33	646.75	613 94
33-35	652.90	613.94
35+	659.05	613 94

A financial analysis of yield tables and prescription combinations completed in 1982 found that all existing stands used in modeling were economically feasible if a regeneration harvest method was used. Later analysis in the FORPLAN model showed that commercial thinning in overstocked stands that had not been previously thinned was uneconomical. As a result, the GF-2 yield table which proposed commercial thinning without a previous precommercial thinning was no longer used in FORPLAN. The general forest yield table that maximizes Present Net Value on a per acre basis is GF-3. This is also the most biologically sound prescription for tree species where precommercial thinning is needed for early stocking control. Stands where commercial thinning is economically and biologically sound include those on relatively level ground and especially where ponderosa pine and Douglas-fir are the major species.

Special management areas where large trees are desired, such as travel corridors, must be thinned in order to achieve the desired size. No other options were entered in FORPLAN. An analysis was done to determine whether longer rotations or increased entries were the most feasible. It was determined that for visual management areas mandatory thinning instead of long rotations was the best approach to creating large diameter trees.

Under maximum Present Net Value, some densely stocked stands in special management areas which require precommercial thinning, and some non-stocked or bareground acres, do not go into FORPLAN solution under the costs and benefits used.

Range outputs represent the amount of forage permitted to be grazed and are measured in terms of animal unit months (AUMs). While the Forest receives grazing permit fees, the value received for the AUMs is not based on market transactions. Therefore, the dollar values per AUM used in the analysis of the benchmarks and alternatives were market price estimations based on the contribution of National Forest grazing to the net income of ranchers.

The Forest Service entered into a cooperative agreement with the USDA, Economic Research Service to develop livestock enterprise budgets for each National Forest. The range budget approach was used for this analysis. Because Forest AUMs are not actually priced in a free competitive market, the calculated price is an estimate of market value. First, returns from all ranch products were determined. Then, all costs of production were subtracted. The remaining returns plus the cost of the Forest Service permits became the residual value of the AUM. The residual value of an AUM to ranch livestock production is comparable to conversion surplus timber value. Based on the information provided in the RPA 1985 Program analysis for the DEIS, and a Regional Office Memo (2340, 9/30/83), the AUM value for the Forest in 1982 dollars is \$7.31.

Range benefits were entered into FORPLAN as net values rather than entering benefits and costs per AUM separately. This was done to utilize the "demand" feature in FORPLAN Version II. A horizontal demand curve was used which depicted one benefit value over the full range of AUMs which would be consumed, and a value of zero for any AUM production beyond that point. Net benefits were utilized so that per AUM costs would also be cut off at this point.

The non-wildlife related recreation and wilderness outputs represent the amount of use consumed on the Forest and are measured in terms of recreation visitor days (RVDs). The wildlife related recreation use is measured in terms of wildlife and fish user days (WFUDs). The values used for these priced outputs were derived directly from the 1985 RPA program assessment. This discussion is a summary of the write-up found in Appendix F the 1985 RPA DEIS.

The development of recreation, wilderness, and wildlife values for the 1985 RPA Program analysis consisted of two steps: (1) development of recreation and wildlife benefit values by activity per RVD or WFUD; and (2) adjustment of values to reflect standard and less-than-standard levels of management.

The Resource Evaluation Group at the Rocky Mountain Forest and Range Experiment Station conducted an extensive literature search to develop the 1985 activity values for recreation. Benefit values for recreation, wilderness, and wildlife activities were developed from recent travel cost models and contingent valuation research (Loomis and Sorg 1982). In-service and academic specialists reviewed the research and activity values and adjusted the initial values to achieve methodological consistency to apply them to regional conditions. The values represent total willingness-to-pay for an additional recreation site, herd unit, or wilderness area. The RVD value by recreation activity that were generated by this study can be found in Table F.4 of the 1985 RPA DEIS.

For program evaluation purposes, these values were subsequently adjusted downwards because:

- The travel cost method represents a total willingness-to-pay. Other resource values in the RPA evaluation represent market price or value of the marginal product. Consequently, the willingness to-pay values were adjusted in an effort to make the recreation values more compatible with values used for other resource outputs.
- The travel cost method estimates values on a site-by-site basis. The method does not address the question of whether regionally or nationally a given quantity of RVDs will, in fact, be consumed if that price were changed.

-It is believed that the travel cost studies are typically done at higher quality sites, do not take into account substitutes to individual sites, and do not accurately measure trip length; consequently, values from these studies may be on the high side when applied to average situations on a region-wide basis.

In response to the first concerns, the values were adjusted based on the relationship between the proportion of recreation provided by the Forest Service and estimates of an average nation-wide demand elasticity for outdoor recreation. It is estimated that nationally, roughly a five percent increase in price will result in a one percent decrease in quantity demanded (Levis 1977). It is also estimated that in 1982 the Forest Service provided 7.5 percent of all outdoor recreation. Consequently, it is roughly estimated that there will be a five percent decrease in price for each percent of the 7.5 percent Forest Service market share or a total decrease of 37.5 percent for clearing the market. Therefore, the initial willingness-to-pay values were reduced 37.5 percent for use in comparing resource allocation choices.

In response to the quality factor, the concept of standard and less-than-standard service was introduced, and the resulting impact on the value of the experience to the recreationist was estimated. If recreation facilities are not fully maintained, the quality of the experience will be lowered. Two different sets of values were developed to account for the standard and less-than-standard outputs. A special study showed that on the average the less-than-standard RVDs are valued at about 53 percent of the value of standard RVDs.

Finally, these values were expressed in terms of the recreation opportunity spectrum (ROS) activity categories in accordance with the way were developed and tracked during the process of analyzing alternatives. The resulting values are depicted in the following table.

TABLE B-IV-3
1985 RPA RECREATION BENEFIT VALUES (1982 \$)

<u>Recreation</u>	Value(\$/RVD)
Primitive (STD)	11.25
Primitive (LSTD)	5.96
Semi-Primitive Non-Motorized (STD)	13.25
Semi-Primitive Non-Motorized (LSTD)	7.02
Semi-Primitive Motorized (STD)	12.13
Semi-Primitive Motorized (LSTD)	6.43
Roaded Natural (STD)	4.97
Rural (STD)	8.47
Rural (LSTD)	4.49
Urban (STD)	11.38
Urban (LSTD)	6.03
<u>Wilderness</u>	<u>Value(\$/RVD)</u>
Primitive (STD)	17.50
Primitive (LSTD)	9.28
Semi-Primitive Non-Motorized (STD)	17.50
Semi-Primitive Non-Motorized (LSTD)	9.28
<u>Wildlife and Fish</u>	<u>Value(\$/WFUD)</u>
Big Game	30.00
Nongame	25.00
Resident Fish	15.00
Other Game	19.00
Wildlife and Fish (STD)	21.00
Wildlife and Fish (LSTD)	14.00

Roaded recreation was not valued in FORPLAN because all alternatives had a greater capacity to supply roaded recreation than was demanded throughout the planning horizon. Therefore it had no effect on allocation or scheduling.

Unroaded recreation, including wildlife and fish related recreation, was valued in FORPLAN. Separate values were used for primitive, semi-primitive non-motorized and semi-primitive motorized recreation. The values in the model reflect the recreation values plus the wildlife and fish values listed above, weight averaged based on historical levels of participation. Per RVD costs were subtracted from these values to produce net benefits. This was done to make better use of the "demand" feature in FORPLAN as explained above for range values.

2. Benefits Outside FORPLAN

Priced benefits not included in FORPLAN were added to FORPLAN benefits using computer spreadsheet programs. Nonpriced benefits were considered in addition to present net value to determine present net benefit.

Wilderness and roaded recreation, including wildlife and fish related recreation, were valued outside of FORPLAN. The values developed for RPA, described in the preceding section, were used.

Commercial harvest of anadromous fish was valued at \$1,050 per thousand pounds of fish harvested. The source of this value was the 1985 RPA.

Firewood was valued at \$2.50 per cord. This is the price charged by the Forest for firewood.

Non-recreation special uses were valued in terms of fees actually paid for these goods and services. These same total benefits for non-recreation special uses were used in all alternatives based on historical data.

Permit fees are also charged for other goods and services such as grazing, camping, summer homes and ski areas. These outputs have nonmarket values developed for them that are considered better estimates of their actual value. Permit fees are not included in benefit calculations for these outputs to avoid double-counting.

The priced outputs, whether included in FORPLAN or added later in a spreadsheet, are used to calculate present net value. Not all benefits can be quantified in dollar terms for use in PNV calculations, however. These benefits must be subjectively evaluated in conjunction with present net value to determine present net benefit. Nonpriced outputs are discussed in more detail in Section A.2 of this chapter.

V. SOCIAL AND ECONOMIC IMPACT ANALYSIS

A. Overview

1. Forest Influence Zone

A "Forest Influence Zone" was delineated to assess current social and economic conditions and to estimate potential changes. The Forest Influence Zone is the geographic area where the majority of forest resources such as recreation, range, timber, water, and wildlife are first used and where public concern is concentrated. Chelan, Kittitas, and Yakima Counties comprise the Forest Influence Zone for this analysis.

2. Population

The 1983 population of the Forest Influence Zone was 248,400 persons. This is almost six percent of the State's population. About one-half of the population lives in rural settings; the other half lives in urban settings. This area has an older age distribution than the State average. Chelan and Kittitas counties have proportionately lower minority populations than the State. Yakima County has a proportionately higher minority population due to the Yakima Indian Nation and a large Spanish-American population. The rate of population growth in the three-county area has been slower than Statewide over the last 40 years. This trend is expected to continue in the future.

3. Economy

Economic activities in Chelan, Kittitas, and Yakima Counties are closely tied to the activities of the Wenatchee National Forest. A large proportion of the residents of this area rely on the commodity and amenity resources of the Forest. Economic activities affecting local individuals include logging, sawmill operations, commercial livestock operations, tourism, and various recreational pursuits. Residents of the study area also have the unique opportunity to participate in nearby forest recreation activities such as hunting, fishing, hiking, and a range of winter sports; thereby generating demand for recreation-related goods and services.

The service, government, agriculture, forest products, and construction industries are the most important in Central Washington. Because the make-up of the service-related and government sectors is influenced to a large extent by the composition and relative influence of the primary (agriculture and forestry) and secondary (manufacturing and processing) sectors, emphasis is placed on describing the importance of these latter industries in the region.

Employment and income data on Central Washington's economy are presented in the following sections. Additional information is provided on the agricultural sector, the region's most important; forest industries, an important sector that is highly influenced by the Wenatchee National Forest, and the local tourist industry, which is related to the recreation influence of the Forest.

In 1984, about 1,575,314 individuals were employed in Washington State. Combined employment for Chelan, Kittitas, and Yakima Counties of about 83,872 people represented six percent of the State's total work force. Employment data for major industrial sectors in the State and the Central Washington counties are presented in Table B-V-1.

TABLE B-V-1
EMPLOYMENT IN MAJOR INDUSTRIAL SECTORS - 1984
 (Number of Persons)

<u>Industrial Sector</u>	<u>Washington</u>	<u>Chelan County</u>	<u>Kittitas County</u>	<u>Yakima County</u>
Total Employment	1,575,314	20,649	7,216	56,007
Agriculture, Forestry and Fishing	32,965	2,241	--	8,017
General Building Construction	64,002	740	128	1,764
Manufacturing (Total)	270,184	2,552	531	6,708
Food and Kindred Products	28,356	644	284	2,530
Lumber and Wood Products	38,367	325	82	1,145
Furniture and Fixtures	2,981	N/A	N/A	143
Paper and Allied Products	15,406	N/A	N/A	436
Primary Metals	11,969	Not listed separately	N/A	N/A

The unemployment rate is an important indicator of the health of a local economy. Due to the relative shortage of jobs in the Forest Influence Zone, the unemployment rates in Chelan, Kittitas, and Yakima Counties were consistently higher than the unemployment rate Statewide (Table B-V-2). (These data on unemployment are recorded by county of residence, not by county of work place. Data on Chelan and Douglas Counties have been aggregated because these two counties represent one labor market.)

TABLE B-V-2
UNEMPLOYMENT RATES 1970, 1975, 1979, 1981, 1983, 1984
 (Percent)

<u>Year</u>	<u>Washington</u>	<u>Chelan-Douglas Counties</u>	<u>Kittitas County</u>	<u>Yakima County</u>
1970	9.1	10.9	9.5	10.7
1975	9.6	10.8	10.5	10.4
1979	6.8	10.5	9.0	9.7
*1981	9.5	12.8	12.7	12.0
*1983	11.2	14.5	13.1	14.9
*1984	9.5	12.3	13.0	14.4

Source: Washington Employment Security Department, Research and Statistics Section. 1980. Personal Communication.

*Washington Employment Security Department, Wenatchee, Personal Communication 1981, 1983, 1984.

Per capita personal income data are available for 1970 and 1978 from the Bureau of Economic Analysis (U.S. Department of Commerce, Bureau of Economic Analysis 1980). In 1970 the per capita income in Washington was \$3,997. Personal income in the Forest Influence Zone was lower. Chelan County ranked highest at \$3,665. The 1970 Kittitas County figure was well below this at \$2,975.

Since 1970 per capita personal income Statewide increased by 178 percent to \$11,110 in 1981. The rank order among the three counties has remained constant, but all three registered larger percentage increases than the State. Personal income increased at a rate of 195 percent in Chelan and Kittitas counties, 192 percent in Yakima County. Table B-V-3 contains data on per capita income for the years 1970, 1978, and 1981.

TABLE B-V-3
PER CAPITA PERSONAL INCOME
(Dollars)

Source: U.S. Department of Commerce, Bureau of Economic Analysis. 1980. Regional Economics Information System. Washington State Data Book, 1983

The economy in the area east of the Wenatchee National Forest rests heavily upon agricultural production. Yakima County is the State's leading agricultural county with a diversified farm base. Its principal products include apples and soft fruit, cattle, hops, potatoes, and wheat. The economy of Chelan County depends primarily upon deciduous orchard crops, with apples being the predominant crop. Kittitas is primarily an agricultural county producing crops and livestock.

The Central Washington area is very important to the State's economy because of its agricultural base. These counties support 36 percent of the State's agricultural employment with Yakima County alone supporting 27 percent (ESD 1984).

The agricultural sector will remain the dominant force in the economy of Central Washington. The strong demand for agricultural products abroad as well as the anticipated strength of domestic demand will, if anything, increase the importance of agriculture in Central Washington. This trend should continue at least through 1990 and may become even more pronounced in the future.

The lumber and wood products industry in the Forest Influence Zone represented 3.7 percent of the State's employment for that industry in 1983 (ESD 1984). Yakima County has the largest lumber and wood products work force among the Central Washington counties, with 1,048 workers in 1983. This represented 17 percent of manufacturing employment in the county, and two percent of total employment. Chelan County's lumber and wood products industry employed 293 workers in 1983, for respective manufacturing and total county employment shares of 14 percent and 1.5 percent. The lumber and wood products work force of 72 in Kittitas County was much smaller in absolute terms, but still accounted for 17 percent of all manufacturing jobs in the county and 1.1 percent of total employment.

Industries in the Forest Influence Zone accounted for eight percent of the State's timber consumption. Specifically, seven percent of all timber used in the Washington lumber industry was consumed by the

seven sawmills located in Chelan, Kittitas, and Yakima Counties. The veneer and plywood industry has a relatively small economic importance in the study area since one mill is located in each Kittitas and Yakima Counties.

The forest products sector of the economy will likely decrease in importance in the future. The extent of this decline, however, will be influenced by several factors. Most notably, the reduction in timber available from private land may cause an overall slump in timber production in the region, and could very likely contribute to a reduction in capacity or closure of local mills. This reduction could lead to further pressure for increasing the harvest from National Forest System lands. This pressure could become particularly intense in the 1990's, or earlier, should housing demand rebound substantially from its low levels in the early 1980's.

Visitors to the Wenatchee National Forest have an impact on the local economy because of expenditures they make for goods and services at establishments nearby. Data on the number of retail trade establishments are available from the U.S. Census Bureau for States and counties. The variables selected as indicators of local economic dependency on recreational use include the following: 1) hotels, motels, and recreational vehicle parks; and 2) eating and drinking establishments. While these components of the services industry receive a significant amount of business from nontourists, the trends in these two service industries reflect growth or decline in the tourist industry.

In Chelan County, there were 44 hotels and motels and 108 eating and drinking establishments in 1972. In 1983, the number of restaurants increased by 16 percent to 125 and the number of hotels/motels increased by 6 percent to 45 establishments. Most growth has been concentrated in the Wenatchee area. Collectively, these establishments supported about 1,890 jobs, or about 10 percent of total employment in the county. Most of the additions include larger motels and restaurants employing more personnel than in 1972. There were only 1,400 jobs in these categories in 1978.

In Kittitas County, the number of eating/drinking establishments decreased in the period during the 1972 to 1983 period, from 78 to 67 establishments in 1983. The number of hotels/motels decreased from 27 to 19. Total employment supported by these retail and service outlets was approximately 1,020 jobs, up from 900 in 1978, or nearly 13 percent of all Kittitas County employment.

In Yakima County, the number of eating and drinking establishments decreased in the period from 1972 to 1983. There were 44 hotels and motels and 309 eating and drinking establishments in 1983. This decrease is misleading, however, because a number of facilities have expanded their capacity. This is particularly true in the City of Yakima where increased capacity has resulted from attempts to increase convention activity.

A particularly active sector of the regional economy will be the tourism sector. An increase in summer and winter recreation activities, particularly along the major travel routes, is expected in the 1980's. The increase in the cost of energy will likely focus the greatest recreational demand near the transportation corridors leading from the Puget Sound area population centers. Recreational demand will be greatest in those areas closest to the Everett-Seattle-Tacoma metropolitan area.

4. Social Structure

The social system surrounding the Wenatchee National Forest is best characterized by its complexity and propensity for change. The complexity is due to the size of the Forest and its proximity to a major metropolitan area in the Puget Sound region, diverse manufacturing and agricultural communities in the Central Washington region, and recent nonmetropolitan growth in the immediate vicinity of the Forest. Change is attributable to rapid metropolitan and nonmetropolitan population growth in the Puget Sound

region and localized growth in nonmetropolitan areas and towns in the Central Washington region. But more significant than population growth is the rapidly changing character of the traditional rural and wildland communities immediately adjacent to the Forest.

The influence of a changing society upon the Wenatchee National Forest can be interpreted by viewing these ongoing changes against those of an emerging advanced-industrial social system. An advanced-industrial social system is a type of society based on advanced complex technology, theoretical knowledge, extensive public regulation of private property and markets, pervasive communication, and social services (Bradshaw and Blakely, 1976).

The original migrants to Washington were drawn by opportunities in extractive industries associated with ranching, mining, agriculture, and wood production, as well as the transportation, trade, and service industries which facilitated resource extraction and industrial development (Johansen and Gates, 1957). Farming, ranching, wood production, and some mining provided the primary economic base for the formation of towns along the eastern base of the Cascades in the major stream drainages. Communities such as Ellensburg, Yakima, Wenatchee, Cle Elum, and Chelan grew in response to markets for basic materials that could be produced from an abundant stock of fertile soils, forage, wood, and coal or minerals.

The populations of these small communities fluctuated with the viability of extraction-based economies. Farming and ranching were relatively stable. Early population growth based upon timber and mining on private land subsided when these natural resources were exhausted.

The Yakima River Project brought about the development of irrigation and hydroelectric power beginning in the first decade of this century, and may have been the single most important factor in the growth of the region. The economic base established by the Yakima Project and other agricultural development provided the basis for long-term population changes in the region. As agricultural production increased, creating additional activity in processing, distribution and services, small towns such as Yakima and Wenatchee grew into regional manufacturing and service centers. Expanding trade, facilitated by rail and water transport, provided increased access to markets for farm products and other regional exports.

Over the last century, the proportion of employment in the primary extractive industries, particularly agriculture, forest utilization, and mining, has declined sharply in contrast with the service sector of the economy. *The shift in emphasis from resource extraction to services has made recreation and tourism a new economic base for some communities.* This shift also places increasing emphasis on public goods such as recreation resources, clean air and water, scenery, and wilderness preservation. *Emphasis on consumption of public goods and services necessitates greater use of political processes for allocating resources.* Government increasingly supercedes market institutions for purposes of allocating public goods, delivering services, and regulating the use of wildland resources.

The dynamic evolutionary status of the advanced-industrial social system also transforms the social environments of many communities in the Forest Influence Zone. Communities demonstrate a mixture of attitudes, some more closely associated with an advanced, emerging technology-oriented social system and others with maintaining their former position as "extractive-industrial" communities. Conflicts within communities often occur as areas grow because of such a mixture of attitudes.

Traditional ranching, farming, and logging communities in the Central Washington region were typified by a way of life in which most people knew one another personally and interacted frequently. Self-reliance and individualism were central values of people living in these communities; outsiders were mistrusted and formal procedures or organizations were not automatically used to resolve differences or local problems.

Residents of agricultural and timber based communities also exhibit certain patterns of behavior that are different from their advanced-industrial counterparts. Specifically, recreational activities of this group tend to be focused on active pursuits such as hunting, fishing, and snowmobiling. The Forest Service has traditionally responded to these local interests in its day-to-day management activities. The favored activities of these groups contrast with advanced-industrial interests in activities such as hiking, cross-county skiing, river rafting, and wilderness camping. Obviously, many urban and suburban residents hunt and fish and otherwise engage in activities similar to those undertaken by the local population, but to a lesser degree.

Pursuit of recreational activities becomes one of the primary means by which citizens in an advanced-industrial social system are exposed to forest lands and management activities. A view of forests emphasizing mainly recreation or tourism is typical for metropolitan residents and even for some of the most recent immigrants to rural and wildland communities. Therefore, it is not surprising that there are often conflicts in rural communities between locals and outsiders, including newcomers. Local residents often feel they have a greater right than outsiders to use the National Forests for recreation, firewood, Christmas trees, and hunting.

The conflict between local and non-local residents over restrictions on traditional private property rights illustrates a key feature of the emerging advanced-industrial social system. The challenge to traditional property rights, whether they are held by the government or by a private person, represents the assertion of the concept of rights found in an advanced-industrial social system. Members of the public increasingly claim common rights to environmental quality, recreation, public health, and other collective goods. These claims are often asserted by organizations which claim to represent the public's interest in the environment. Thus, members of a public interest group or class of citizens may feel they can legitimately make claims which supercede those of the private or public landowner.

Intermixed ("checkerboard") land ownership patterns on the Wenatchee National Forest could increasingly become a source of conflict. The expanding set of public goods assigned to National Forest lands by an advanced-industrial social system will be increasingly inconsistent with intensive forest management on adjacent private lands. Forest users and interest groups are likely to become increasingly concerned with inconsistent land uses along these ownership boundaries.

Emergence of an advanced-industrial social system in the Puget Sound and Central Washington regions has also changed decision-making institutions. Non-market political and administrative processes have enjoyed expansion in both their jurisdiction and authority. While the role of markets in allocating resources has suffered from increasing regulatory limitation, this trend is closely related to the changing concepts of land tenure and signals the increasing success of groups organized to pursue particular interests. Interest group formation and political action has increasingly replaced economic behavior as the force driving resource decisions. The Forest Service has accommodated this trend by incorporating opportunities for public involvement in its planning and decision-making processes.

Use of interest groups and political influence as instruments to shape decisions related to environmental quality and other public goods is not simply an urban or suburban phenomenon. Interest group action has replaced traditional person-to-person influence on resource allocation in many rural communities.

Most of the preceding information in this chapter is excerpted from a socio-economic overview of the Wenatchee National Forest, updated in 1984, that was prepared by the Envirosphere Company of Bellevue, Washington. This document is on file in the Forest Supervisor's Office.

B. Sources of Data

Impacts of alternatives and benchmarks on employment and income in the Forest Influence Zone were estimated using input-output analysis. Returns to the federal Treasury and payments to counties were estimated based on anticipated receipts for goods and services.

1. Economic Impact Analysis

IMPLAN was used to perform the economic impact analysis for the FEIS. IMPLAN is an input-output model software program which resides on the micro computer at the Wenatchee National Forest Supervisor's Office in Wenatchee. It is not the purpose of this discussion to describe IMPLAN in detail. This can be ascertained in the User's Manual (August 1982) and several other papers which describe the IMPLAN system in detail.

Economic input-output (I-O) analysis is a procedure for describing the structure of inter-industry dependencies in a regional economy. The region, in this case, is Chelan, Kittitas, Douglas and Yakima Counties. I-O analysis is based upon the interdependence of the production and consumption sectors of the economy for the area being studied. Its foundation rests on the concept that industries must purchase inputs from other industries, as well as from primary sources (e.g., natural resources), for use in the production of outputs which are then sold either to other industries or to final consumers. Thus, a set of I-O accounts can be thought of as a "picture" of an impact areas economic structure at one point in time. In this case, the point in time is 1982. This structure is represented as a mathematical transactions matrix of buyers and sellers in the economy.

The proposed output levels associated with each alternative are represented as changes in the current levels of final demand for these outputs in the IMPLAN model. The resulting production requirements needed to satisfy these changes in final demand and the flow of industrial inputs and outputs can then be traced via the I-O accounts to show the linkages between, and the impacts on the different industries composing the regional economy. Through mathematical matrix manipulations, the estimated direct, indirect, and induced impacts can be evaluated. The impacts concerning most people in the local economy are those dealing with the changes in employment and personal income.

a. IMPLAN Data Base

The IMPLAN model has a database consisting of: (a) a national level technology matrix, and (b) a file of estimated activity levels for total gross output, 6 final demand components, 3 final payment indicators, and employment estimates for 466 industrial/business sectors (Alward and Palmer, date unknown). The national level technology matrix is based on a 1972 Department of Commerce I-O model that was converted to an "industry by industry" basis and updated to 1977 using the RAS procedure (Clopper, Almon, and others, 1974).

b. National Data Base Reduction to Impact Area

The county level information is based on a 1982 data set constructed by Engineering Economics Associates of Berkeley, California. Utilizing the national technology matrix and the control totals for Chelan, Kittitas, Douglas, and Yakima Counties, a data reduction method is employed to develop the input-output table for the economic impact area. The method used exploits the property of "openness" displayed by smaller regional economies when compared to the National economy (Richardson, H.W 1972). Smaller regional economies exhibit much greater tendencies to import and export goods and services than does the national economy. Therefore, they are more "open" than the national economy. Based on the assumption that trade balances are the principal difference between national and regional purchase patterns (e.g., industry production functions are identical but regional imports and exports make local inter-industry transactions different), the supply-demand pool technique for data reduction was adopted

Once this step was done, input-output model of the 1982 local economy was compared against alternate sources of information regarding employment by sector in order to verify its reasonableness.

c. Final Demand Expenditures

For each alternative, the I-O model was used to translate proposed changes in resource output levels from their current levels of production into changes in employment and income for the Forest Influence Zone.
