123 MANAGE THREATENED, ENDANGERED AND SENSITIVE PLANTS AND ANIMALS IN A MORE CONSERVATIVE FASHION AND AS A HIGHER PRIORITY.

COMMENTS INCLUDED:

“These species should be given the benefit of the doubt by preserving maximum habitat.”

“More attention should be given to maintenance of ... individual species.”

“...wildlife studies ‘WHEN FUNDS BECOME AVAILABLE.’ Instead, THE HIGHEST PRIORITY SHOULD BE GIVEN.”

“Inventories for populations and distribution of threatened, endangered and sensitive species should be conducted as soon as possible.”

“...admitting your lack of data.”

“I am especially concerned about protecting the environment for endangered and other unique plant species.”

“I support increased protections for native plants...”

FOREST SERVICE RESPONSE:

The public is concerned that the Forest Service will not protect Threatened, Endangered and Sensitive species. As a result of input from the public and various agencies (including the Washington Department of Wildlife and Washington Department of Natural Resources) and in consultation with the US Fish and Wildlife Service, the Forest Service has re-written the Threatened, Endangered and Sensitive species sections. Changes have been made in allocation of habitat, prescriptions, goals, and Forest-wide standards and guidelines allowing more proactive management for these species. Some examples of changes draft to final include:

1. The goal of threatened, endangered and sensitive species management has changed from maintaining habitat for recovery to providing habitat to facilitate de-listing of listed species (see the Goal section of Chapter IV of Plan for specific wording).

2. The number of sites to be protected for bald eagle nesting has been increased from one to eight (see the Forest-wide Standards and Guidelines section of Chapter IV of the Forest Plan).
3. Old growth habitat for northern spotted owls is now managed without timber harvest where in the draft EIS management would have allowed some timber harvest (see the old growth prescription in Chapter IV of the Plan).
4. Species Management Guides will be developed to provide management direction and summarize available information for each sensitive species or for each threatened or endangered species for which a recovery plan has been written.
5. A "Plants" section has been added beneath the "ENDANGERED, THREATENED OR SENSITIVE SPECIES" category of the Forest-wide standards and guidelines.

The information available on threatened, endangered and sensitive species has been expanded between the draft EIS and the final EIS (e.g., spotted owl inventories have been done and more information has been gathered to allocate bald eagle nest sites). There is still a major need for research and maps of current and potential habitat and known population locations. Population models, especially for animal species, are also necessary. These have been identified as needs in the FEIS and Forest Plan.

Lack of inventories on species populations and habitat have the potential to cause losses of critical individuals or habitat. However, this should not happen because the standards and guidelines require (Forest-wide Standards and Guidelines, Chapter IV of Plan and Forest Service Regional Manual Direction) that all threatened, endangered and sensitive species be inventoried and assessed for all projects (Environmental Impact Statements, Environmental Assessments, Categorical Exclusions). This guidance helps assure that these species are not overlooked in projects and contributes to the development of a Forest-wide database.

Knowledge of individual species requirements, although currently limited, is recognized as necessary. Research is called for in the Plan and should help to address this need

124 WILL SPECIAL HABITAT AREAS BE SET ASIDE FOR THE PROTECTION OF RARE PLANTS?

COMMENTS INCLUDED:

"I urge preservation of areas where there are endangered species, and a strengthened protective system for them."

"These sensitive endemic plants must be protected in special areas"

"Critical areas must be identified and set aside"

"I also want to see areas in Wenatchee set aside for rare plants."

FOREST SERVICE RESPONSE:

Currently there are 50 species of plants on the Wenatchee National Forest sensitive plant list (up from 34 when the draft plan came out). None are federally classified as endangered or threatened although the plant species *Hackelia Venusta* has been proposed for recommendation as endangered or threatened. The Forest is committed to the protection of these species and coordination with appropriate federal and state agencies to assure this end.

The draft and final plans do not include areas specifically set-aside for species protection. There are several reasons for this:

- The location and extent of the populations of most of these species is unknown. Although the Forest actively consults with the Washington Natural Heritage Program on their database for element locations, the database is incomplete. "Completing" the database for a 2 million acre Forest would be a tremendous job and the inventory would be constantly changing as plants are dropped from the list and new plants are added or sighting of listed plants increase.

- Often the lands where the "best" populations of a species are found are not located on National Forest land.

- Species Management Guides are being developed (by priority with most threatened plants first) and these guides will provide an effective method of assuring protection of these species.

- One mechanism for setting aside areas for preservation of a plant is through the Special Interest Area designation. However, this recreational use classification may be inappropriate if it provides less protection to the species than the management guide requires.

In the relatively short time since the draft there has been an effort to delineate areas that are appropriate for Special Interest Area designation. Most of these are areas of old growth forest deemed unique for their aesthetic qualities, wildlife and plant habitat values or place in maintaining biological diversity. As part of this effort, a number of areas were included in several non-scheduled harvest prescriptions including: SI-2, OG-1 or SI-1.

A number of special interest areas including some of those proposed in Alternative F have been added to the preferred alternative either in the SI-2 or OG-1 prescriptions. Alternative F was based on environmental coalition recommendations. There is also the opportunity to include other areas in the future should they be proposed and found necessary. This is also true of Research Natural Areas. If the Research Natural Area Committee proposes an area for inclusion into the RNA system, the Forest will make every effort to fulfill that need.

New special interest areas to be included as a result of recommendations by the public and Forest Service employees include:

Of the proposed botanical and geological areas found in Alternative F, 5 have been added to the preferred alternative (one other-Lake Creek remains in both alternatives). Added to the botanical areas list was Hornet Ridge (for old growth Ponderosa Pine) and added to the geologic areas were all those proposed in Alternative F (Kloochman Rock, Goose Egg Mt., Rimrock and Blue Slide). Note: In some cases the acreage and proposed boundaries for these areas are not the same as those proposed in Alternative F.

The two botanical areas proposed in Alternative F but not added to the preferred alternative were Camas and Gene Creek. Camas (proposed to protect Wenatchee Larkspur) was not added because it was felt that an SI-2 designation, mainly recreational in focus, might not be appropriate for the preservation of that species. Further, the proposed 800 acre area was not all National Forest system land. Finally, it was felt that the Species Management Guide being developed for Wenatchee larkspur would protect the species. Although Gene Creek was proposed, another area, around Rattlesnake Springs, was deemed a better area.

125 WILL THE RESEARCH NATURAL AREAS FROM ALTERNATIVE F BE INCLUDED IN THE PREFERRED ALTERNATIVE? THEY SHOULD RECEIVE MORE EMPHASIS IN THE PLANNING PROCESS.

COMMENTS INCLUDED:

“I...support the Special Botanical Areas and Research Natural Areas provided for in Alternative F.”

“I strongly favor the RNA and Botanical Areas included in this Alternative.” [F]

“Botanical and Research Natural Areas, as outlined in Alt. F, should be established.”

“The Plan should list information needs related to RNA identification, selection and management.”

“I am disappointed that the issue of RNA’s is not given greater scope.”

FOREST SERVICE RESPONSE:

The public expressed strong support for the RNAs proposed in Alternative F of the Draft Environmental Impact Statement. All of the RNAs proposed in that alternative are also listed in the preferred alternative. The Forest Service intends that all proposed Wenatchee Forest RNAs become established in the preferred alternative.

The Forest Service also fully supports and actively participates in the effort to locate needed cells in the Research Natural Area System on the Wenatchee Forest. These cell needs are determined from the Washington Natural Heritage Plan. Since the Draft Plan and EIS were published a number of changes have been made in those documents to better address the RNA program.

RANGE

126 WILL LIVESTOCK GRAZING INCREASE UNDER THE FOREST PLAN?

COMMENTS INCLUDED:

“The declining demand for beef nationwide, the minute amount of US beef contributed by National Forests at great cost to the taxpayer and ecosystem integrity, the small number of ranchers who benefit from grazing rights on the Wenatchee National Forest, and the breadth of impact of grazing to the Wenatchee National Forest add up to a general inability to justify maintained or increasing permissible AUMs.”

“Following my recommendations for increases in the GF allocation, increases in range outputs should occur. Grazing should be limited for 5-7 years after regeneration harvest, unless needed as a tool to accomplish regeneration goals.”

“Let me add my opposition to any increase in livestock grazing levels.”

“Allowing livestock grazing is fine and could slightly increase.”

“I oppose any increases in the level of livestock grazing.”

“My last suggestion would be to reduce the number of grazing permits allowed on National Forest land.”

FOREST SERVICE RESPONSE:

The Code of Federal Regulations (36 CFR 222) and Forest Service policy require that Forest Service administered lands that are suitable for livestock grazing be made available for use by qualified livestock operators. The decision to be made in view of regulation and policy is how much of the forage on suitable lands can be allocated to livestock use recognizing the forage needed by wildlife and the biological needs of the forage plants which provide protection for soil and water resources.

The total of 22,000 AUM's per year projected to be permitted in the first planning period is less than ten percent (10%) of the total forage produced on the Forest. The remaining ninety percent (90%) is left for wildlife, plant maintenance, and soil and watershed protection (see Chapter III in the DEIS and Chapter III and IV FEIS). The suitable acreage to be used by livestock is less than ten percent (10%) of the total Forest acres. Existing and expected future forage levels available for wildlife will exceed any expected use by wildlife. Available forage is not and will not become a limiting factor for wildlife using the Wenatchee National Forest.

Because the majority of respondents were concerned with proposed increases in permitted grazing use, the Forest examined the assumptions contained in the DEIS and reduced the use objectives for the Preferred Alternative.

As explained in Chapter III of the DEIS and Chapter III of the FEIS, estimates of the amount of increase in demand varied by source, but all agreed that there will be an increase in demand for livestock forage. Increase in use varies by alternative, but the increase for the life of this Forest Plan and for all alternatives is expected to be 400 AUM's which is approximately a two percent increase over the current use. Due to the uncertainty of demand we are projecting only an additional 1,000 AUM's increase in decades 2 through 5, or about a five percent increase above current levels. This is also expected to be accommodated on existing range allotments.

Some important standards used in the management of livestock forage include:

- Any increases in forage allocated to livestock will be preceded by site specific Range Allotment re-analysis. Forage needed for wildlife will be allocated to wildlife use before livestock increases are granted.

- Structural improvements needed for proper management of existing range areas will be in place and properly maintained before increased allocations are made to livestock.

Increases in grazing on existing allotments will emphasize the use of livestock as a tool for improving vegetation and promoting ecological diversity for a wider variety of uses.

127 GRAZING ADVERSELY AFFECTS WILDLIFE HABITAT, SOILS, WATER QUALITY AND NATIVE PLANT COMMUNITIES.

COMMENTS INCLUDED:

“Levels of livestock grazing must decrease in the interest of multiple use on the Wenatchee. It is critical that the diversity of native plants be maintained and that the invertebrate and vertebrate species which depend on non-grass species be maintained as mandated in the NFMA.”

“I take issue with the contention that grazing improves the habitat for native plants and wildlife. In fact I believe the Forest Service may be in violation of the law by endangering these species by doing so.”

“Grazing devastates the structure and composition of native plant communities.”

“34 species of plants on the Wenatchee are listed as endangered, threatened or sensitive species. The plan basically ignores the negative effects of its management activities.”

“Decrease grazing to allow regeneration of native plants and allocate more forage to wildlife. Livestock grazing at current levels is detrimental to wildlife and native plant species.”

“We oppose any increases in the level of livestock grazing and support increased protection for the native plants, including establishment of all botanical and research natural areas outlined in alternative F.”

“Your plan to increase livestock grazing is highly questionable and I would suggest further study on the impact of grazing on native plants, soils, and stream banks.”

“While we are dubious about the positive effects of cattle grazing on fisheries habitat, we do not see large scale impacts of grazing on fisheries in the forest at this time. However we feel that the amount of grazing (AUM’s) should be held constant.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

FOREST SERVICE RESPONSE:

The previous response also responds to many concerns in these comments. When properly implemented and administered, livestock use of range forage can be not only compatible, but also beneficial to other resource values. As the Forest Plan is implemented we envision a shift in historical practices to better unite range science techniques with grazing, so that livestock use becomes a tool for improving vegetation and promoting a diversity of vegetation for a wider variety of uses. Moreover, livestock grazing will continue to contribute to the social and economic well being of local communities.

There are many standards and guidelines contained in Chapter IV of the Forest Plan which require the protection of other resources. Unique and Sensitive Plants (referred to as Native Plants by many respondents) are required to be protected by law. The Forest Service will protect these plants from any management activities including grazing by livestock. Permitted grazing is coordinated through an Allotment Management Plan. These documents contain the specifics of management intensity and depict the level of outputs and coordinations measures necessary to meet Forest Plan objectives.

128 THERE ARE MANY POTENTIAL SOURCES OF CONFLICT BETWEEN LIVESTOCK AND WILDLIFE FROM DISEASE TRANSMISSION. DOMESTIC SHEEP CAN PASS PARASITES AND DISEASE TO BIGHORN SHEEP, AND CATTLE CAN TRANSMIT BRUCELLOSIS AND BLUE-TONGUE TO DEER

COMMENTS INCLUDED:

“Finally, domestic sheep should not be allowed to graze near bighorn sheep habitat. Diets overlap, and bighorn have no natural defense against diseases and parasites that can be passed.”

“Grazing lowers the water quality and transmits disease and parasites to wildlife.”

“No mention was made in the DEIS of protection of game from livestock diseases”

“Grazing by cattle is often a source of disease to the wild animals..”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0062, 0500, 0582, 2021, 2715, 2888, 2964, 3177, 3187, 3225, 3573, 3575, 3606, 3873, 3911, 4263, 4511

FOREST SERVICE RESPONSE:

While the potential for disease and parasite transmission between livestock and big game exists, for the most part, these species have coexisted for decades. Examples of this coexistence are common place on the Wenatchee National Forest as well as on lands of other ownership.

Although there are no known problems with transmission of disease and parasites between livestock and big game on the Wenatchee National Forest we are aware of the possibility of this occurring, particularly between domestic sheep and bighorn sheep. The key concentration areas of bighorn sheep are known on the Forest and we do not plan to expand grazing allotments into these concentration areas.

When properly implemented and administered, livestock use of range forage can be compatible. As explained in chapter III of the FEIS, in certain instances and with proper management grazing can be beneficial to other resources. Chapter IV of the FEIS indicates that some adverse impacts associated with grazing are expected. The Chapter describes the extent and degree of impacts, including those associated with grazing, and describes mitigation measures that will be taken. These mitigation measures are translated into Standards and Guidelines contained in Chapter IV of the Forest Plan. The Forest Plan also contains a monitoring plan to assure that the Standards and Guidelines are being implemented and are effective.

129 GRAZING SHOULD NOT BE ALLOWED TO CONTINUE IF THE FOREST DOES NOT REALIZE A PROFIT. WHY SHOULD THE PUBLIC LANDS BE USED TO SUPPORT THE INDUSTRY BY THE AMERICAN TAXPAYER?

COMMENTS INCLUDED:

“Rather than a small dependence, most grazing on the Wenatchee National Forest is done by rancher’s relying heavily on the Federal subsidy.”

“The values received for AUM’s are not based on market transactions, but are on grazing permit fees. Why is the value for grazing determined in this way rather than like the other resources.”

“Grazing appears to serve an economic need and provide revenue, but dues should approximate private holdings and not serve to subsidize ranchers.”

“...I believe the number of domestic animals using FS lands should not be increased, and a greater fee per animal should be collected to help off set FS expenses.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0062, 0063, 0066, 0147, 0577, 0579, 1950, 2036, 2131, 2715, 2753, 2789, 2856, 2897, 2956, 2996, 3127, 3140, 3177, 3232, 3355, 3374, 3394, 3429, 3462, 3518, 3572, 3803, 3867, 3872, 3873, 3911, 4089, 4142, 4169, 4261, 4302, 4415, 4457, 4465, 4485, 4498, 4511, 0018S

FOREST SERVICE RESPONSE:

Grazing fees on National Forest lands in the 16 Western States are calculated through the formula prescribed in Executive Order (EO) No. 12548 of February 14, 1986. This fee formula, in most respects, is the formula established in the Public Rangelands Improvement Act of 1978 (PRIA). The EO modified the PRIA formula by establishing a floor level of \$1.35 per Animal Unit Month (AUM). For fee purposes, the Forest Service has used Animal Month (AM) as the pricing unit rather than the AUM. Basically, the formula allows for adjustment of fees based on livestock prices and production costs during a given year. The important point to consider, however, is that grazing is a management tool for improving vegetation, promoting other resource objectives (such as site preparation for reforestation or suppression of vegetation which competes with young conifer trees). Administration of livestock grazing is only one of several activities (i.e., range vegetation management, wild horse and burro management, noxious weed inventory and management, and geographic systems inventory and analysis) which is appropriately funded by range management in general. To assess the total cost of the range management activity against the cost to administer livestock grazing is misleading.

130 LIVESTOCK CAN COMPETE FOR THE SAME FOOD SOURCES AS WILDLIFE, PARTICULARLY DURING THE WINTER.

COMMENTS INCLUDED:

“The DEIS states that approximately one half of the Forest’s winter big game range is located within commercial livestock allotments and there is competition in some areas. Big game winter range is very limited and competition in these areas is certainly not advisable.”

“With most winter range being located on private land, it would seem that wildlife would be forced to survive on winter range grazed down by cattle during the summer and fall.”

“We believe that any new grazing should be directed away from big game winter range.”

“I think some of the livestock grazing should be directed toward summer range, so that winter range can be improved to support wildlife increases.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0005, 0582, 2715, 3698, 4263, 4435, 4485

FOREST SERVICE RESPONSE:

In many instances, grazing can and will be used as an important tool in the management of forage vegetation to achieve wildlife habitat objectives. It is important to recognize that forage for livestock is also an important use of rangeland vegetation and in some instances allocation decisions between resource uses will need to be made. In the EW-1 (big game habitat) allocations, which includes winter range, forage will be allocated in favor of big game. Only excess forage would be made available to livestock. (See Chapter IV of the Forest Plan.)

131 THE DRAFT DOCUMENTS LACK QUANTITATIVE DATA CONCERNING THE CONDITIONS OF RANGELANDS ON THE FOREST. IN ORDER TO PROPERLY ASSESS THE PROPOSED FOREST PLAN, THE PUBLIC NEEDS TO HAVE A SITE SPECIFIC ANALYSIS OF RANGE CONDITIONS ON THE VARIOUS ALLOTMENTS.

COMMENTS INCLUDED:

“You are required to determine range condition and trend, 36 CFR 219.20 (a) Yet no information on condition or trend of existing rangelands is provided here.”

“The draft documents should include site-specific analyses of range conditions on the various allotments.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

3553, 4511, 4485

FOREST SERVICE RESPONSE:

Site specific data exists in Allotment Management Plans, copies of which are maintained at both Ranger District Offices and the Forest Supervisor's Office. Due to the extensive nature of these documents, it is simply not practical to include them as part of the Forest Plan or Environmental Impact Statement. Allotment planning is prioritized by vegetative condition and management concerns within the allotment, particularly the condition of the riparian zones. A part of this process includes the updating of the data base to insure the plans are based on current and accurate information.

The present condition and trend of existing allotments is summarized in Chapter III of the FEIS. Also Tables II-1 and II-3a in the DEIS and FEIS summarize the Condition and Trend of existing allotments in Alternative A/NFMA. Throughout the Wenatchee National Forest allotments are in fair or better condition. Overall trends are stable or upward.

132 GRAZING SHOULD NOT BE ALLOWED TO CONTINUE ON LANDS WITHIN WILDERNESS AREAS.

COMMENTS INCLUDED:

“It appears that wilderness will be grazed at high to moderate intensity. Why is this allowed? Are there wilderness allotments?”

“In wilderness, we believe it would be appropriate to phase out livestock allotments as they expire.”

“Permitted grazing within dedicated wilderness should be phased out as rapidly as possible, even though legally permitted to continue. Cattle and sheep, and the wilderness experience does not mix well.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0040, 0385, 0484, 0582, 2835, 2966, 2996, 3232, 3621, 4169, 4485, 4494, 4498

FOREST SERVICE RESPONSE:

Section 4(d)(4)(2) of the Wilderness Act states that grazing in wilderness areas, if established prior to designation of the area as wilderness, “shall be permitted to continue subject to such reasonable regulations as are deemed necessary by the Secretary of Agriculture.” To clarify any lingering doubts, legislative intent as expressed by the Congressional committee stressed that there would be no curtailment of grazing permits or privileges in an area simply because it is designated as wilderness. As stated in Forest Service regulations (36 CFR 293.7), grazing in wilderness areas ordinarily will be controlled under the general regulations governing grazing of livestock on National Forests. This includes the establishment of normal range allotments and allotment management plans. Within the goals of the Forest Plan, livestock grazing in Wilderness will continue to be a management tool available to meet range vegetation management objectives.

If a wilderness grazing permit is waived back to the government its continuation would be reviewed on its own merits.

133 NOXIOUS WEEDS ARE A PROBLEM CAUSED BY GRAZING, LOGGING, ROAD BUILDING TRAILS AND OTHER PHYSICAL DEVELOPMENTS.

COMMENTS INCLUDED:

“Domestic livestock introduce noxious weeds and carry parasites.”

“Grazing and increased campground development is likely to bring in weeds.”

“So it is prudent to withhold road building for a few years to avoid the problem of weed control with herbicides.”

“The weed species that benefit from logging are already too predominant due to the expansion of disturbed lands.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0063, 1972, 2021, 2073, 2888, 3067, 3177, 3187, 3208, 3210, 3225, 3911, 4511

FOREST SERVICE RESPONSE:

We agree that noxious weeds are a serious problem and the Forest Service is concerned about their proliferation. A programmatic Environmental Impact Statement for Vegetation Management in the Pacific Northwest Region of the Forest Service has recently been completed. Forest Plan directions and site specific projects involving integrated pest management techniques will be tiered to this programmatic document. An important part of our noxious weed control and management program is prevention by ensuring that available sites are occupied with desired native vegetation. Preventive management is critical to an effective control program.

134 HOW ARE PREDATORS AND PREDATION OF LIVESTOCK HANDLED?

COMMENTS INCLUDED:

“Do not allow grazing permittees, or others, to kill any wild animals to control predation of livestock.”

“Predator protection should be practiced as long as hunting continues to take a significant number of animals. Natural predation should not be hindered. Sheep and cattle ranchers should be made to bear the cost of any predation upon their animals.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

2353, 2956

FOREST SERVICE RESPONSE:

Control of predators through hunting or by other reduction programs is not under the authority of the Forest Service. Laws and policies concerning control of predators (other than hunting) on federal lands are administered by the U.S. Fish and Wildlife Service. Hunting of predators, and any other animals on National Forest lands, is allowed under the laws and policies of the State Game Departments within the state where the National Forest Lands occur. The Forest Plan Standards and Guidelines and decisions on administration and use of the Forest deal only with those resources and uses where the the Forest Service has been given that authority through Federal Law.

TIMBER AND FIREWOOD

135 WHAT HAS BECOME OF THE “MARGINAL COMPONENT” DEFINITION USED IN EARLIER TIMBER PLANS?

COMMENTS INCLUDED:

“Has the marginal timber component been programmed for harvest on the Wenatchee Forest?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0040, 0112, 4493

FOREST SERVICE RESPONSE:

The marginal component of the Timber Management Plan has been offered for sale in the past. Some “marginal” sales have gone without bid, others were logged successfully. Under the proposed plan “marginal” would be redefined as either “suitable” or “unsuitable” for timber management using the criteria from NFMA and regional guidance.

136 HARVEST LEVELS SHOULD BE LOWERED BECAUSE OF THE VOLUME OF TIMBER AL-READY UNDER CONTRACT.

COMMENTS INCLUDED:

“Immense volumes of Wenatchee National Forest timber already purchased, plus huge volumes being cut on private lands, there is an opportunity to reduce the annual sale volume without devastating impacts on timber companies.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0388, 0528, 0605, 1955, 1970, 1971, 2119, 2134, 2877, 2929, 2953, 3083, 3144, 3162, 3232, 3255, 3308, 3317, 3430, 3579, 3606, 3871, 3872, 4071, 4245, 4425, 4426, 4434, 4465, 4477, 4489, 4496, 4498

FOREST SERVICE RESPONSE:

Volumes under contract have declined from 850 million board feet to 370 million board feet as of October 1, 1988, as a result of increased harvest activity, “buy back,” and defaulted sales. The updated volume under contract was considered in the revised demand analysis for the final Plan and EIS. Volume under contract is continuing to decline as a result of harvest activity exceeding the volume being offered for sale.

The level of timber under contract normally needed by the industry to allow an even and continuous flow of logs is equal to 2 1/2 to 3 years of annual sale. This allows some time for planning and scheduling of harvest activities prior to the actual logging.

137 EXPLANATION OF THE GENERAL FOREST PRESCRIPTION AND HARVEST LEVELS.

COMMENTS INCLUDED:

“The specific degree or amount of timber harvesting under each of the GF-Management prescriptions is not clear. The specific nature and the difference between the prescriptions is difficult to ascertain. Indeed, the text appears to be purposefully vague.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0047, 0069, 0141, 0582, 0738, 0796, 0879, 0896, 1952, 1960, 2729, 2730, 2755, 2787, 2841, 2883, 2912, 3045, 3174, 3207, 3255, 3257, 3305, 3469, 3775, 4418, 4452, 4485, 4497, 4499,

FOREST SERVICE RESPONSE:

We agree that the different General Forest Prescriptions were confusing. Between the draft and final we have combined these into one General Forest Prescription. Variations in intensity will be determined by a site-by-site analysis. General guidelines on the management intensities is based on the ForPlan analysis. The details on the variations of intensity are found under the timber resource narrative in Chapter IV of the Forest Plan.

138 WHAT LEVEL OF HARVESTING SHOULD BE DONE ON THE WENATCHEE.

COMMENTS INCLUDED:

“I say no more cutting of old growth. In fact, let’s stop all logging in the National Forests.”

“Timber is like any other crop; if it becomes too old, it has no value for lumber or as a haven for wildlife. It has been demonstrated that it can be harvested and replanted allowing a suitable compromise for all situations.”

“When specific oriented groups and persons such as the Wenatchee Chamber of Commerce Wenatchee Economic Development Committee, Yakima Chamber of Commerce, Representative Clyde Ballard, Senator George Sellar and many others speak out clearly in favor of supporting the timber industry and our assertion that 138 MM Bd Ft. per year is not adequate, then I think the needs and interests of the general public are being distinctly and dramatically stated.”

“Allowable cut -- I have before me a July 1986 issue of Forest Industries Magazine showing U.S. lumber production and consumption over the last decade... Clearly the U.S. demand for softwood lumber is not being met by U.S. production at present levels.”

“While I cannot support a major reduction in timber harvest, I am also opposed to any increase in harvest. At our current level of harvest the economy & conservation efforts appear to be fairly well balanced.”

“Please don’t reduce the timber cutting if the mills really need it. If they can say timber is scarce--up goes the price of lumber. (We can’t afford to build a new house even at today’s prices.)”

LETTERS WITH COMMENTS OF THIS SUBJECT INCLUDE:

4121, 4127, 4131, 4139, 4144, 4147, 4153, 4167, 4183, 4185, 4188, 4190-4191, 4199, 4205, 4212, 4223-4224, 4226-4227, 4231, 4235-4238, 4240, 4243-4244, 4246, 4259, 4261, 4263-4264, 4281, 4287-4292, 4295-4296, 4298, 4300, 4303, 4312-4403, 4411, 4420, 4422-4424, 4427, 4430-4431, 4433, 4438-4439, 4445, 4447-4448, 4454, 4459, 4464-4465, 4467-4468, 4477, 4483-4484, 4488-4491, 4493, 4496-4497, 4501, 4507, 4511, 4534, 4551, 4676, 9000-9002, 9004-9005, 9009, 9011, 9013-9014, 9022, 9025, 9027, 9034, 9037-9038, 9040, 9045-9046, 9049-9050, 9052, 9054, 9060-9061, 9064-9066, 9070-9073, 9080, 9082, 9088-9089, 9092, 9095, 9102-9105, 9107-9110, 9112, 9520, 9804, 9862, 0005S, 0011S, 0021S, 0042S, 0068S, 0070S, 0074S, 0086S, 0104S, 0176S, 0183S, 0601S, 0663S, 0672S, 0675S, 0695S, 0715S, 0733S-1037S, 1039S-1051S, 1058S, 1144S, 1168S, 1176S-1177S, 1183S-1184S, 1193S, 1195S, 1203S-1204S, 1213S, 1215S-1216S, 1239S-1240S, 1360S-1368S, 1383S-1400S, 1438S-1570S, 1589S-2013S, 2052S, 2103S-2154S, 2202S-2238S, 2254S-2268S, 2278S-2302S, 2321S-2362S, 2368S-2389S, 2391S-2444S, 5000S-5004S, 5006S-5020S, 5022S-5040S, 5044S-5066S, 5111S-5112S

FOREST SERVICE RESPONSE:

Based on the large number of comments on the harvest level and on the "Essential Alternative," a new alternative, J, was added between the draft and final.

Determination of the allowable harvest level is a complex calculation based on biological, economic, and social/political factors.

In simple terms it is a calculation based on the amount of tree growth that can be perpetually sustained under a given set of conditions. This calculation takes into account the amount of volume existing on areas suitable for timber harvest. It subtracts the volume projected for harvest and then adds in the amount of growth expected on existing stands and newly regenerated stands. We propose to increase the level of planting of appropriate species of trees from parents selected for rapid growth and disease resistance.

Using these techniques we will produce more wood per acre managed than under current timber management plans.

A significant portion of the American people want more areas reserved from harvest especially in currently unroaded areas, while others want to either maintain or increase harvest levels. We propose to meet those seemingly opposing desires by increasing the yield per acre of land managed to provide timber production. We propose to increase the number of acres planted with appropriate species. Although the per acre yield will increase, the total harvest per year will be reduced from the current level, but above the preferred level shown in the draft Forest Plan.

In addition we will space and weed young trees so they have room to grow, but with little space wasted. Thinning and weeding to obtain optimum growth is now proposed on 50-70 percent of the new forest stands. This is a considerable increase in management intensity from the DEIS which will be more costly.

139 WHAT IS THE FOREST POLICY AND ACCOMPLISHMENT IN REFORESTATION?

COMMENTS INCLUDED:

"In areas where logging is permitted a program of reforestation should be initiated immediately."

"Please state what the current policy is regarding tree planting, and if it is effective."

↳
“I believe the best interests would be served if the Wenatchee would be reforested, rather than deforested.”

“Replanting and growth management should be high-level management priorities throughout the general Forest.”

“What minimum stocking levels are assumed for various species? What happens if a planted site does not meet minimum levels? Is there an obligation to replant sites on which previous planting efforts have failed? How have data on replanting success been used in scheduling timber harvest on sites on the WNF? That is, are there any combinations of slope, aspect, altitude, soil type, and annual precipitation which dictate special harvest restrictions or deny harvest at all because of regeneration problems?”

“Even subsequent tree planting is not very effective - very few of the young trees survive and weeds take over.”

“I am so angry when I see hillsides clearcut with obviously no attempts at reforestation- and then to find that I am paying subsidies because timber receipts do not cover the cost of building logging access roads!”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0066, 0150, 0415, 0434, 0582, 0748, 1681, 2036, 2120, 2123, 2742, 2842, 3020, 3052, 3100, 3101, 3162, 3267, 3515, 3649, 3746, 3773, 3890, 3991, 4132, 4173, 4174, 4296, 4485, 4497, 9034, 0030S, 0052S, 0342S, 0696S

FOREST SERVICE RESPONSE:

It is obvious from the comments we have not done an adequate job of presenting our policy and accomplishments in reforestation. More than 1 1/2 million seedling trees are planted each year on the Wenatchee National Forest.

As shown in Chapter IV of the Plan, it is the goal of the Forest to “Use silvicultural techniques that insure prompt and adequate regeneration of appropriate species.”

Areas such as north slopes that face away from direct sun, can typically be regenerated by clearcutting and planting. Usually a mix of species is planted to maintain diversity. On some areas, brush species are mixed with the conifers for wildlife use.

We have received ample funding for reforestation for the last several years. Most of the funding comes from deposits required of the timber purchaser to reforest the areas harvested. In addition, Congress has appropriated sufficient funds to plant all suitable burned areas deforested by wildfire.

Survival and growth of replanted seedlings are required the first fall after planting, and are checked again during the third growing season. Results from these examinations are summarized each year. The results for 1988 are:

1ST YEAR SURVIVAL AND GROWTH RESULTS

<u>Acres Planted</u>	<u>Avg. trees per acre planted</u>	<u>% Survival</u>	<u>%Satisfactory growth</u>
4,678	390	85%	89%

3RD YEAR SURVIVAL AND STOCKING RESULTS (Trees planted in 1986)

<u>Acres Planted</u>	<u>Avg. trees per acre planted</u>	<u>% Survival</u>	<u>%Satisfactory growth</u>
3,047	355	84%	93%

To the best of our knowledge all clearcut acres are planted or are reforested naturally five years after harvest. Sometimes these trees are hidden by other vegetation and may not be visible from casual or roadside observation. For this reason we do systematic examinations of our plantations to determine stocking of conifers and any need for replanting after both the first growing season and the third. Additional, less formal checks are made on most areas the 2nd and 4th seasons and periodically thereafter.

Our records show 93% of our three year old planted cutting areas are successfully reforested and the majority of the other 7% will be replanted to assure reforestation within five years of harvest. Any area we do not have reasonable assurance of successful reforestation within five years will not be part of our scheduled harvest base.

The area with existing trees where we do not plan regeneration harvest because we can not assure regeneration of a new forest stand is approximately 200,000 acres. See land suitability table in Chapter II of the Forest Plan.

140 WHAT LEVEL OF HARVEST CAN BE SUSTAINED.

COMMENTS INCLUDED:

“Sustained yield is just not happening. Timber is *slow* growing.”

“The actions proposed in the Wenatchee Draft Forest management Plan are more than a little horrifying. I am in favor of *sustained yield* timber harvesting, but the Draft Plan goes far beyond what would appear reasonable and prudent in terms of forest management.”

“Timber--I strongly maintain that a long-term sustained yield is the only reasonable way to go. To take more timber off an area on an annual basis, than is being replaced by annual growth, is short-sighted and greedy.”

“I do not prefer the accelerated harvest for National Forest lands. I favor sustained yield because I feel current income is not as important as the even flow of income and its effects on the nearby communities as well as National Forest employment levels and related matters involved with these two factors.”

“It is my belief that every forest in the National Forest system should maximize the amount of sawtimber and other tangible forest products within the confines of the theory of sustained yield. The National Forest is a public timber resource which should stabilize.

Under the preferred alternative in the Wenatchee Forest Plan, little regard is given for these principles. On the contrary, the Plan has no regard for its long-term effects on wood supply and community well being in terms of employment and timber receipts to the counties. I implore you to review your Plan with the goal of increasing the harvest to a level of 180 MMBF or greater. This would be within the confines of the sustained yield of 211 MMBF.”

FOREST SERVICE RESPONSE:

Our timber yield calculations are based on growth and inventory plots scattered over the Forest. We are confident that the yields predicted can be achieved in perpetuity under the management prescriptions we have included in our Plan.

If yield decreases in the future it will be due to restrictions on acres available for timber management or limitations on methods of harvesting, not as a result of the biological growth potential of the Forest.

Our preferred alternative and all others, except Alternative I, are based on non-declining sustained yield. Alternative I describes a procedure for departing from the non-declining sustained yield by allowing timber harvest to remain at historic sell levels for 10 years followed by a reduction after the majority of the old growth stands are harvested. This would depart from the non-declining constraint but not from long-term sustained yield.

The definition of sustained yield of products and services is “The achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forest System without impairment of the productivity of the land.” 36 CFR 219.3

It is our judgement that our proposed harvest level can be sustained in perpetuity without impairment of the productivity of the land.

141 TIMBER SALES BENEFITS SHOULD ALWAYS EXCEED COSTS.

COMMENTS INCLUDED:

“No timber should be sold at a loss. Minimum requirements should be made for profits on all sales. If the timber sale does not meet these profitability requirements it should not be sold.”

“It is far more economical in the long run to promote recreational use of the Forest, rather than artificially supporting the timber industry by building roads that cost more than the value of the timber they lead to.”

“Leave uneconomical areas to the birds. Put extra effort into high yield areas and abandon slopes, rocks, poor soil, high altitude or dry locations.”

“We are not opposed to development of natural resources where that development make economic sense. That means the development must financially support itself without any subsidy. Logging is a business. Its not done as a favor to the Forest Service or the American Public. It’s done for profit! If it’s going to be done, then it should be self-supporting.”

“In most areas currently designated for clearcutting, such as Lake Creek Basin and Devil’s Gulch, the projected cost of road building alone far exceeds the value of the timber produced. Logging and clearcutting is not always justified by the number of board feet of lumber produced in such areas. Great care should be taken by those in authority to ensure a fair deal for our Forests-and its inhabitants.”

FOREST SERVICE RESPONSE:

36 CFR Ch II (7-1-87) 219.12 requires a schedule of outputs that will maximize the net public benefits over the area covered by the Forest Plan. There is no requirement that each sale return a profit. However, every sale must collect minimum appraised value rates. For Western White Pine and Ponderosa Pine the minimum base rate is \$20 per mm bd ft. The minimum for Douglas-fir, Western Larch and Cedar is \$10, and other species \$5. These rates must be collected regardless of the costs the timber purchaser may need to expend including roads.

In addition, the purchaser pays for the costs of debris disposals and reforestation. If the sale is appraised above these minimum rates some of the collected money may be used for other resource enhancement projects.

We have provided total timber receipt and total cost figures in Chapter III of the FEIS for the forest as a whole. There are still questions about how this applies to individual sales. Respondent #9007 brought up two specific areas. Perhaps values from Lake Creek and King Bee (Devil’s Gulch) would be helpful to clear up the misconception that roads cost more than the value of the timber produced on sales in these areas.

<u>Sale</u>	<u>Species</u>	<u>Additional Required Stumpage price</u>	<u>Slash Disposal Cost</u>
Lake Creek	Ponderosa Pine & White Pine	146.80	8.26
	Douglas-fir and other species	27.25	8.26
Total Sale Value	\$444,090.00		

The road costs for the timber sale above are \$16.96 per MM. Bd. Ft. or \$142,474.00. Remaining sale value after road costs is \$301,616.00

<u>Sale</u>	<u>Species</u>	<u>Additional Required Stumpage price</u>	<u>Slash Disposal Cost</u>
King Bee Resale	Lodgepole, White and Ponderosa Pine	165.75	5.61
	Douglas-fir and Western larch	109.00	5.61
	Grand fir and other species	112.00	5.61
Total revenue expected	\$1,588,336.00		

All roads were constructed under an earlier contract at a cost of \$544,003.00. This leaves over a million dollars in revenue after road costs from the King Bee Resale. In addition, the original purchaser paid buy-out costs. Some respondents recommend a switch from logging to recreation to reduce subsidy of a few at the expense of many. Wilderness and unroaded recreation currently bring in little revenue but do have costs. This could be considered a subsidy also. Developed campground users pay fees which may or may not cover the cost of a campground.

It is proposed that in the future all resource programs in the Forest Service display both costs and revenues. Currently only timber is required to do this. Values for 1987 and 1988 are on file at the Forest Supervisor's office. For a further discussion of this issue please refer to the timber costs and returns section in Chapter III of the FEIS.

142 THE FOREST HAS NOT CONSIDERED ALL THE FACTORS PRESENT IN DETERMINING WHAT LANDS ARE SUITABLE FOR SUSTAINED HARVEST.

COMMENTS INCLUDED:

“To me the single most important point is: All suitable lands for timber production must be bought under Forest Mgmt. The Forests for tomorrow (future generations) must be started today. I don't believe mature and over mature stands of timber can be `saved' for future Generations. Those stands will (and are now) eventually succumb to insects, disease, and/or fire. Nothing is to be gained by attempting to `save' a forest for the future. It is contrary to wise mgmt and we are losing the growth that those lands could be contributing now. The result of not managing or trying to save the forest is less total wood growth and less total timber production, making future timber supplies unnecessarily scarce and expensive. By reducing timber harvest now (Alt C), you are reducing future growth and timber for the future.”

“High altitude logging: Most areas have unstable slopes and poor soil quality. Logging in these areas is dangerous, very damaging to the plant communities and often unprofitable. Further, regeneration of trees is often difficult and expensive (the cost generally seems to fall on the taxpayer). These areas are worth more as attractions to outdoors users than as low-quality lumber or pulp.”

“Indications are that the new Forest Plans now being formulated are excluding large areas of commercial timberland which can be harvested by helicopter. These excluded lands appear to be in part the results of an outdated method of financial assessment now being used by the Forest Service Planning staff. These excluded lands are commercial timberlands and the use of an updated system of costing would place some, if not all, of these timberlands back into the timber base.”

“Using available resources; both expertise and funds to more intensively manage the good sites that have already been cut over will yield higher returns in a fifty-year time frame than rapping sites with low productivity; low value species; poor soils; extreme slopes and high elevations of their timber.”

FOREST SERVICE RESPONSE:

36 CFR Ch II 219.14 is the basis for determining timber resource land suitability.

Of the allocations that have a scheduled timber harvest, there are approximately 140,000 acres judged to be unsuited for sustained timber production for commercial use. The reasons in order of importance are:

1. Areas where regeneration can not be reasonably assured. These include both low, dry and high elevation and mid-elevation areas where tree regeneration is questionable due to identified vegetative, aspect, elevated slope, and soil conditions.
2. Areas where unstable soils would likely cause irreversible resource damage.
3. Lands not cost efficient over the planning horizon. These are primarily burned over non-stocked unroaded lands where the cost of reforestation would exceed future discounted benefits. Also see the Social/Economic section in Appendix B of the FEIS.

Based on public input, a field review of randomly selected sites to validate the suitability determination was made in 1987 by the Forest Silviculturist. District personnel, the Forest Soil Scientist, interested conservationists and industry representatives were invited to attend.

The review judged the previous suitability calls to be 88 percent correct. Incorrect calls on lands judged to be unsuitable for timber management were offset by incorrect calls on lands judged to be suitable. Therefore, there was no adjustment in acres judged suitable for timber harvest. A record of acres checked for suitability and results, including some photos, are on file and can be viewed at the Forest Supervisor's office in Wenatchee, Washington.

143 HARVESTING RELIES TOO HEAVILY ON CLEARCUTTING.

COMMENTS INCLUDED:

“What logging has to be done, should be done with as little clearcutting as necessary.”

“Small (less than 20 acres) clearcuts are not very detrimental, also shelterwoods hold the character of the land. I've worked in the woods and I know them as a livelihood. I also love this Forest and don't want to see it ruined.”

“I want timber harvesting to be conducted in the following manner: Clear cut in lower elevations not visible from any state or interstate highways, selective cutting only in the higher elevations.”

“I am well pleased with the Forest Service's shelterwood cutting. Not only do I feel that this is a good Forest practice, but such a cut area is aesthetically pleasing.”

“All this clearcutting worries us! What's happening to our wildlife, our streams, and our fish. More important, what are we leaving for our future generations? People have to make a living in such away that a living is provided for coming generations. *Clearcutting isn't doing the job*”

“I applaud the examples of selective logging the Forest has conducted in the Snoqualmie Pass-Cle elum area. More logging in the Forest should be managed that way.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0023, 0040, 0047, 0062, 0069, 0150, 0239, 0262, 0286, 0298, 0386, 0442, 0484, 0541, 0562, 0579, 0601, 0722, 0736, 0744, 0793, 0796, 0869, 0879, 0896, 0901, 1939, 1940, 1960, 2030, 2032, 2037, 2070, 2081, 2131, 2358, 2397, 2729, 2740, 2749, 2765, 2775, 2785, 2787, 2791, 2841, 2845, 2851, 2872, 2879, 2883, 2915, 2916, 2940, 2942, 2956, 2964, 2981, 3010, 3015, 3017, 3032, 3050, 3057, 3065, 3107, 3141, 3156, 3186, 3207, 3209, 3255, 3257, 3305, 3311, 3322, 3347, 3383, 3394, 3408, 3469, 3520, 3521, 3532, 3576, 3588, 3602, 3610, 3632, 3642, 3670, 3704, 3706, 3767, 3768, 3793, 3808, 3814, 3817, 3862, 3876, 3914, 3940, 3950, 3989, 4069, 4149, 4235, 4236, 4271, 4295, 4418, 4421, 4447, 4449, 4452, 4453, 4485, 4488, 4490, 4494, 4497, 4498, 9005, 9065, 0018S, 0026S, 0040S, 0051S, 0054S, 0056S, 0060S, 0062S, 0065S, 0112S, 0176S, 0182S, 0721S, 0723S, 1055S, 1168S, 1176S, 1243S, 1246S, 1380S, 1406S, 1422S, 1585S, 2042S, 2046S, 2055S, 2061S, 2071S, 2240S, 2241S, 5071S

FOREST SERVICE RESPONSE:

Appendix H of the FEIS has a discussion of cutting methods. In general, clearcutting is to be prescribed on a site specific basis and only when it is the optimum method of regeneration to meet multiple use objectives.

Our expected harvesting by harvest type is shown in Appendix A of the Forest Plan. Approximately 60% of the harvested acres are some type of partial or shelterwood cut. The remaining area to be clearcut will have units averaging less than 20 acres in size. Requirements for clearcut harvest size based on National Forest Management Act guidelines and regional interpretation are detailed in Appendix H.

144 INTENSIVE MANAGEMENT SHOULD BE USED TO MAINTAIN OR INCREASE TIMBER HARVEST.

COMMENTS INCLUDED:

“Timber harvesting - where timber harvesting is the primary concern there should be more management of the stands such as commercial thinning, brush control when competing with young trees and tree planting-diversity must also be maintained.”

“I believe it is clear that the allowable harvest level on the Forest has been too high and must come down to comply with the direction and intent of NFMA and other Federal law. However, I think the levels envisioned in Alt. C may be too low. I think the Forest Service should increase harvest levels through intensive management on good growing sites throughout the Forest. I think the agency should plan on spending more money to produce timber from the Forest than a private landowner might because Congress and the administrations have consistently shown a willingness to fund high levels of timber management. They have a high concern for community stability and jobs, and I think we should too, so long as it can be accomplished without slighting other resources. I think these increase in selling should come from commitments to thinning, fertilization, and planting of superior seedlings.”

“GF-4 was chosen for 80% of the prescription for Alternative “C”. That prescription is clearcut - plant - clearcut at age 100 or 110. Such a scenario is ridiculous when viewed with your current on-the-ground management, and the proposed plan inclusion of 3,000 acres annual precommercial thinning. I favor intermediate treatments which accelerate the growth rate on the selected crop trees. Concern for root rots, insect resistance, and fire hazard encourages stand management through regular treatments. Total yield will also be increased and individual tree size will be larger than with the GF-4 scenario. GF-5 and GF-1 will both give better results for both timber and recreation values. There needs to be an injection of common sense into the for-plan process. Closer review by people on the ground should improve your program.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0066, 0409, 0411, 0412, 0577, 0582, 0635, 0724, 0844, 1313, 2123, 2264, 2781, 2785, 2879, 2919, 3228, 3427, 3459, 3462, 3487, 3596, 3742, 3760, 3793, 3991, 4011, 4092, 4156, 4179, 4180, 4181, 4235, 4271, 4450, 4494, 4497, 0074S, 0176S, 1193S, 1195S, 1250S, 2042S, 2055S

FOREST SERVICE RESPONSE:

We agree with your comments for the reasons you give. We have decreased the amount of GF-4 intensity area in the final plan. The clearcut only intensity has application and is being used extensively in some timber types by both private and public landowners. However, on the Wenatchee, the low demand for small diameter trees and the increased values for all resources appears to justify using common sense and increasing precommercial thinning acres.

The amount of commercial thinning that will be economical is uncertain. Our current analysis shows that commercial thinning in previously unmanaged stands often results in blowdown and increased disease, without substantial increase in wood production.

145 WILL PLANTING CLEARCUTS WITH TREE IMPROVEMENT STOCK RESULT IN MONO CULTURES, REDUCTION OF SOME SPECIES, OR TREES TOO WEAK TO STAND UP TO WIND STORMS?

COMMENTS INCLUDED:

“Only 6 of 16 tree species on the Wenatchee National Forest are considered important enough commercially to warrant investment in tree improvement (DEIS-III-60) Even though revegetation will be done by mixed planting, it would seem that with the enormous acreages involved that some tree species which are presently in low densities will become even rarer. Cedars for example are in high demand and were once common in Riparian Zones. How will this and other species fare in the future and how will demand for these trees be met?”

“Silvicultural systems must promote stand structure and species composition which avoids risk of environmental damage (Plan IV-94). Does this mean that in replanting that a diverse mixture of tree species will be used and that selective harvest methods will be favored?”

“Super trees grow fast but research reveals that what you gain in growth you lose in wind damage (trees weaker).”

0577, 0901, 2138, 3622, 3813, 4498, 9018

FOREST SERVICE RESPONSE:

We are planting western redcedar in riparian and other wet areas where they are the best suited species. Natural regeneration is also favored by leaving western redcedar along streams for seed and stream shade.

We plant ponderosa pine, Douglas-fir, noble fir, Pacific silver fir, western larch, lodgepole pine, western red cedar, and engelman spruce every year. We, on occasion, plant grand fir, sub-alpine fir, western hemlock, and black cottonwood. However, these last species are prolific natural seeders, and wherever present tend to increase with fire protection and any type of partial cutting methods. These species also tend to be somewhat less desirable for structural timber and are not favored in high recreation use areas, due to root and stem diseases.

Our cutting methods are designed to encourage natural regeneration. Reforestation emphasizes using a variety of planting stock selected from better than average parent trees. We do not at this time have plans for any clonal seedlings. All of our seed orchards are wind pollinated and resulting progeny are a wide mixture of (adjacent) better than average parent trees. A minimum of 50 different parent trees are used in each seed orchard to insure genetic diversity. In addition, wild pollen from adjacent rogued stands will add even more genetic diversity.

We select seed only from parent trees that are proven wind firm, so our future trees should not be weaker. We have seen some added top damage following fertilization, but that was primarily from feeding by porcupines and wood rats, not wind.

146 WE QUESTION YOUR YIELD PROJECTIONS FOR TIMBER GROWTH.

COMMENTS INCLUDED:

“The process of yield table development for both existing and future stands builds on this uncertain foundation. Empirical yields are no better than the inventory from which they are drawn. This puts them in a questionable light regardless of what technique was used to derive them.”

“Managed stand yield tables on the WNF need additional careful evaluation. The analysis is plagued with unknowns and there is a high potential for bias in the data and the model as used. These tables are extremely difficult to support as they stand.”

“I project the current annual growth for the Wenatchee National Forest may be significantly less than given in the proposed Forest Plan.”

“Yield tables are overly conservative. Initial stocking levels are too high and rings per inch growth is too low for managed stands. GF-1 FORDRY Regime is illogical and should be eliminated. Our intent is to produce sawtimber, so GF-3, 4, and 6 are economically undesirable.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0583, 1127, 3085, 4483, 4484, 4485, 4489, 4490, 4534, 1370S, 1578S, 2042S

FOREST SERVICE RESPONSE:

Yield tables use existing Wenatchee inventory plots for initial trees per acre. These compare very favorably with numbers of trees and overall volume production shown by the timber inventory.

GF-1 Fordry is currently being used to represent north slope dry area sales such as Forest Mountain and Barrett Creek, GF-5 is being used on these same sales on south slopes where suitable ponderosa pine seed or shelterwood trees are available and needed. GF-5 utilizes shelterwood cuttings to encourage natural regeneration but allows for planting on approximately 50 percent of the area to encourage rapid regeneration of preferred species.

Using our best estimation of costs and values, the ForPlan computer model selects mostly GF-3 and GF-4, with some GF-1 and GF-6. We believe that GF-5 has more silvicultural application than indicated by economics alone. GF-5 is an excellent silvicultural practice for many hard to regenerate south slope stands.

147 YIELD TABLES

COMMENTS INCLUDED:

“On the surface it appears that it would be worth treating more land with the GF-1 prescription because in wet Forest, 7 to 9 inch trees are worth \$222 and 19 inch trees are \$535.50. Even larger trees can be worth up to \$613.94. Will local mills be able to retool to handle the much smaller logs and will these logs satisfy the full range of future demand for wood products?”

“Is the low timber production in the EW-2 area compared with GF areas solely a result of the different stand used (110 years for GF-1 and 130 years for SP-2)? What is the growth rate in EW-2 areas at 110 years?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

4483, 4484, 4485, 4496

FOREST SERVICE RESPONSE:

We agree with your comment on increased value for larger trees. Larger trees also provide for increased wildlife, recreation and visual values. For these reasons, we have increased the application of thinning strategies to produce larger tree sizes on a majority of the Forest acres.

The timber production in EW-1 is lower than GF-1 due to longer rotations and no commercial thinning. EW-1 equals GF-3 at 110 years.

148 INVENTORY - THE TIMBER INVENTORY IS OUTDATED AND INSUFFICIENT. STRATIFICATION OF THE FOREST DOES NOT REFLECT THE TRUE VARIETY OF OPPORTUNITIES OR OTHER RESOURCES RELATIONSHIPS ON THE FOREST.

COMMENTS INCLUDED:

“Why evaluate the Alternative NC when it inflates timber outputs by using obsolete inventory data, outdated yield tables and ignores other resource interrelationships?”

“FORDRY and FORWET: These terms refer to ecotypes that are too broad to be lumped together and cannot be incorporated into intensive forest management schemes. A vegetation map of the forest management land base would be a much more powerful planning tool.”

“There has never been assessment of the reliability of the Wenatchee’s inventory data either as a whole or as it was stratified for planning. Suspicion arises from a comparison of measured tree ages on a given plot with the stand age assigned. Discrepancies range above 160 years. Such errors bring into question other data such as timber type.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

3241, 4419, 4484, 4497, 4498, 1578S, 2168S

FOREST SERVICE RESPONSE:

The inventory of the timber resource was completed in 1977. We have attempted to update it by subtracting areas harvested or sold up through Dec. 31, 1988.

We have also shown growth of trees for the period from 1977 to 1994, the mid point of the forest plan period. The "growth" is an extension of the growth rate found in 1976 when the trees were measured. Negative impacts such as three years of drought, woodcutting, salvage logging, and areas of more than "normal" mortality are not accounted for.

Positive growth measures are also not accounted for. These include areas fertilized and thinned since the inventory. Areas planted with tree improvement stock are accounted for in the managed yield table.

Because our inventory is outdated, we currently are contracting for a new land satellite mapping system that will be able to map more efficiently. Using computer generated mapping will allow much improved capabilities for stratification of land areas and enhanced ability to measure growth and yield potential on smaller tracts of land. We do not expect much change in overall allowable sale quantity, however, this will allow for a better definition of investment opportunities.

If the allowable sale quantity does change significantly as result of the new inventory, the forest plan will be revised. This would be most likely at the five year check point.

149 EVEN-AGED MANAGEMENT WILL REDUCE THE DIVERSITY OF THIS FOREST.

COMMENTS INCLUDED:

"Even-age management-under the preferred Alt. Most of the Forest would be logged under even age system clear cutting and shelter wood. This will reduce the diversity of the Forest by decreasing the amount of mixed aged Forest which is better for plant and animal diversity and converting the Forest to a vast tree farm. Even age management also has more impact on water quality and temperature wildlife soils and scenery. NFMA and the regulations for NFMA contain numerous requirements for the consideration of impacts caused by the silvicultural system selected and for the maintenance and enhancement of diversity. I do not feel that the DEIS adequately addressed these impacts and concerns as required by law."

"Research seems to be saying that we can't take it all without paying the penalty of long-term debt. In other words, I believe we are going to have to leave a percentage of commercially valuable trees standing in the Forest to be recycled through all stages of the natural process."

"Furthermore the biological diversity in our old growth Forests may be essential if our current practice of replacing clear cuts with single species and single age trees does not work."

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0900, 2383, 3204, 3227, 3775, 4271, 4497, 4498, 9018

FOREST SERVICE RESPONSE:

Clearcutting and shelterwoods followed by a combination of planting and natural regeneration can in fact result in a wider diversity of conifer and other species. Some stands of lodgepole pine, or Pacific silver fir for example have very limited species diversity. Harvest can allow for planting additional species including other conifers and browse plants.

Also see Appendix H of the FEIS for a discussion of selection of silvicultural harvest methods. Only about one third of the forest is managed for timber production. Large portions of this area are to be managed with selective harvest and long-term shelterwood harvest. Less emphasis is given to clearcutting in the FEIS than was proposed in the Draft Plan. Beyond this, we recognize the importance of leaving biomass in the forest after harvest. Timber sale planning specifies the volume and distribution of woody debris to be left on the forest floor.

150 THE WENATCHEE CONSTRAINT LIMITING MAXIMUM CLEARCUT IN A DRAINAGE TO 25% AT ANY ONE TIME.

COMMENTS INCLUDED:

“The standards adopted for achievement of harvest dispersion limit clearcuts to 40 acres, require stocking of trees to 4-1/2 feet high prior to adjacent cutting and limit adjacent cutting for a decade. These should be viewed as the maximum standards, certainly not the norm. We agree with the selection of 25% dispersion factor for regeneration cutting. We feel this is the best of the three alternatives because it offers the most limitation on forest fragmentation.”

“We do not think it is appropriate for the Forest Service to incorporate activities on adjoining lands into their harvest dispersion constraint analysis.”

“The over-cutting on private lands on the Forest is well known. We support the 20% alternative for implementing the dispersion MR.”

“With studied timber harvest dispersion, the Marten, Three-toed woodpecker, Pileated woodpecker, and the spotted owl will adapt...if smaller harvest areas are developed in a checkerboard area. Lack of habitat: logging and reforestation would open new range for big game. Riparian zones could be protected by planting shrubs and cottonwoods.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

2134, 0030S, 0719S, 1370S, 1380S, 1577S, 2064S, 2240S, 2308S

FOREST SERVICE RESPONSE:

This constraint will continue the dispersal of created openings and insures that a diversity of tree age will be maintained. This policy will apply to areas of mixed ownership and areas of solid National Forest lands.

151 DOES HARVESTING OF TIMBER DAMAGE OTHER RESOURCES AND CAUSE IRREVERSIBLE DAMAGE?

COMMENTS INCLUDED:

“Logging and roads cause siltation and higher water temperatures that destroy native fisheries in the streams, rivers and lakes. The roads also bring in more people, more noise, more cans, more-----.”

“Timber harvesting is good for wildlife regardless of popular belief.”

“On those areas that are logged, constant monitoring should be done to protect fisheries and water quality.”

“Plan omits the effect of logging steep hillsides and valleys in regard to flooding or irrigation and its effect on fish and plant life.”

“Any process which reduces forest cover, either man caused, burning or natural wildfire, will result in increased water yield. According to water/timber interrelationship study conducted by Dr. David Wooldridge continued harvest of the old growth forests in these basins should provide between one-third and one-acre foot per year of increased water yield per acre harvested. Increased yields will diminish over time as young forests are established and grow. Increase will diminish to pre-harvest amounts in 15-20 years as a young forest grows. The increased water yields resulting from the differing Alternatives is truly insignificant. Under Alternative “C” the first decade increase of 13,300 acre feet is only two-tenths of one percent.”

“I think timber companies in the region have shown responsible management in the past regarding timber harvest. Their timber harvesting practices are actually beneficial to the forests and critical to economy locally and across the U.S.”

“Where logging does take place, any trails or trailheads that get destroyed by the logging procedure should be re-established. It must be cheaper to do this than build new trails.”

“I think its ecologically healthy to harvest timber sensibly. It reduces the bad effects from insects an forest fires, and ultimately helps to improve the forest food chain for animal survival.”

“Alternative C would result in much clearcutting. We’ve noticed that clearcuts alter the pattern of snow deposition and melt out fast in the spring. When snow is fresh and snow cover is good, clearcuts provide good skung. However extensive clearcutting can adversely affect water and snow quality. The final Forest Plan should make more use of shelterwood systems where some forest overstory is maintained. This would prolong snow melt, benefit the watershed by reducing flooding and siltation, have favorable effects on the timing of runoff, and of course provide good places to ski where the snow is protected from the sun (and therefore not crusty, icy or wet with surface water).”

FOREST SERVICE RESPONSE:

When planning a timber sale, specialists (wildlife and fish biologists, hydrologists, archeologists, economists, etc.) analyze the predicted effects and advise the Forest managers on what, if any, mitigation measures are necessary and available to reduce the impacts to other resources.

The Forest Plan significantly increases the budget for resource coordination and specialists support to the timber program, particularly, for soil and water, recreation, fisheries and wildlife. However, the amount of coordination that is funded varies by the way in which the Forest prepares its annual budget and how Congress funds the Forest Service.

Whether or not increased funding is received, some impacts of timber management are unavoidable and can result in irretrievable or irreversible losses, such as loss of wilderness characteristics. For a description of these impacts, see FEIS Chapter IV and Appendices B and C.

Management indicator species are selected to portray the effects of management activities. The overall objectives for these species are to maintain or improve their habitat; however, some specific areas of habitat may be altered in achieving the Forest-wide objectives.

Meeting other resource objectives, such as improvement of elk habitat, anadromous fish habitat or riparian areas, and maintenance of visual quality, may prevent some timber harvest from being accomplished or result in modification of a timber sale. This may lead to reduced volume or smaller cutting units. Achieving multiple-resource objectives in this manner is more costly than managing solely for any individual resource benefit.

Fewer acres are proposed for harvest and roading under the FEIS as compared to the draft. See old growth and roadless area discussions for acreage and rationale for the decreases in harvest areas.

152 TIMBER HARVEST EFFECTS ON SUMMER STREAM FLOWS.

COMMENTS INCLUDED:

“The DEIS seems to claim that the effect of earlier runoff in logged-off areas is offset by overall greater runoff in those areas.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0389, 0579, 1970, 1997, 2201, 3011, 3175, 3240, 3576, 3819, 3875, 4434, 4494, 4497, 4501

FOREST SERVICE RESPONSE:

Complete removal of trees from a study area in Lake Creek basin on the Wenatchee National Forest resulted in an increase of 5.4 inches of summer moisture within the soil profile over uncut plots. (Herring 1968.)

“Clearcutting frequently increases base flows during period of low flow...” (Harr 1982.) A more definitive study in north Idaho found the following. “Creating larger openings on the north aspect will develop a high potential for increasing total water yield. On the south aspect this will have a minimal or even a negative effect on water yield increases.”

As clearcutting is most commonly used on northerly aspects on the Wenatchee, a net increase in stream flow is expected. For additional information refer to the response to comment 116 regarding water quality.

153 WHAT WILL BE THE EFFECT OF WILD AND SCENIC RIVER DESIGNATION ON ALLOWABLE SALE QUANTITY?

COMMENTS INCLUDED:

“Concerned about the effects on 10,000 acres of commercial timber land within the lower segments of the American and Cle Elum rivers where river designation could result in reduced tree vegetation management. Will this flexible management deviate from current management practices used near streams of this class type? If the nine rivers are put under Wild and Scenic River management how accurate a figure can be derived as to how this will impact the ASQ under flexible management?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

2195S

FOREST SERVICE RESPONSE:

Regulations for management of rivers classified as Recreational or Scenic under the Act seems comparable to management direction for scenic travel and riparian allocations under the Forest Plan. Virtually all of the rivers will be placed under these two allocations until they are considered for Wild and Scenic River allocation by Congress. However, we would expect that there would additional costs for consultation with other agencies and the public if projects are proposed in Wild and Scenic River zones. In summary, we expect a very slight falldown in the ASQ but some increase in costs to the government as a result of river classification.

154 WHAT IS THE FUTURE FIREWOOD POLICY FOR THE FOREST?

COMMENTS INCLUDED:

“Moderation has been the byword of the Naches Ranger District so far, in its management of wood cutting and other uses of the Forest.”

“I would like to see this philosophy of moderation and respect for the natural life, continued.”

“Since Holden Village strives to use renewable resources, the future harvesting of fire wood for village heat is of prime importance.”

“The wood cutting was not addressed. This is very important to many local residents. Are firewood gathering policies going to be changed in the near future? Are resources adequate to meet demand without affecting wildlife or causing other damage.”

“Let public cut firewood before burning brush.”

“Before useable firewood is consumed in slash burn, **please** make a greater effort to make it accessible.”

“I would like to know why the lumber industry has all kind of fire wood in the slash piles This makes the Forest look like hell. Why can't the people that need the wood go pick it up. I personally think the system is in dire need of better options.”

“All slash should be windrowed and burned, followed by immediate diversified replanting.”

“Firewood cutters are stealing thousands of cords of green logs from the Wenatchee Forest each summer. I believe this problem is much bigger than anyone realizes. Since dead and down wood is all but used up on existing road systems - wood cutters are cutting green trees back away from the roads, and using them for wood. This needs to be looked at.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0062, 0296, 0297, 0308, 0349, 0352, 0353, 0355, 0391, 0425, 0492, 0494, 0495, 0498, 0499, 0505, 0506, 0546, 0582, 0603, 0642, 0648, 0651, 2699, 0793, 1741, 1963, 1986, 1987, 2066, 2493, 2832, 2847, 2962, 3009, 3083, 3297, 3572, 3862, 4466, 9065, 9114, 0068S, 2240S

FOREST SERVICE RESPONSE:

It is forest policy that utilization of logging residue for firewood and other uses will be the favored method of reducing fire hazard where ever practical. We expect firewood will continue to be readily available on the forest. Distance to quality firewood may increase. Increased restrictions on snag removal may also be needed to maintain wildlife perch and nesting trees for birds and other wildlife. Some standing trees, especially western larch, are cut for firewood while still useable for sawlogs. We expect additional tree cutting restrictions and enforcement may be necessary to limit this in the future.

155 INSECTS AND DISEASES OF TREES CAN BE SEEN FROM DIFFERENT POINTS OR VIEW.

COMMENTS INCLUDED:

“The National Forest Management Act directs the Forest Service to recognize that the National Forests are ecosystems (Norse Et Al., 1986). Timber harvests are justified on many roadless areas for the management of insect, fungal, and parasitic plant populations. With these proposals, there is no consideration of the contribution of these organisms to the natural, ecological processes occurring on the forest. While these organisms may act to reduce the timber resource available for harvest, they effectively enhance other resource values of the Forest (the availability of which is mandated by the multiple use sustained yield act) such as, scenery, forage and snag habitat.”

“How about such issues as blow down or diseased timber. Should this timber just sit there and rot & perhaps infest more of our Forest? Without roads, it will.”

“Mixed stands satisfy lots of problems. Mono stands encourage bug infestation, and are visually boring. More emphasis on lodge pole pine, cedar, larch.”

“Your concern for the high mortality of trees and insect infestation again is not a reason, it is a justification. You provide all kinds of reasons for doing this or that piece of destruction, but they are not real reasons; they are justifications. They are not persuasive.”

“New Alt.: In due consideration to the problem of disease, a mono culture forest system should be replaced with a multiple cultured forest.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0605, 0577, 3239, 3398, 4450, 1058S

FOREST SERVICE RESPONSE:

NFMA states that, “silvicultural methods shall not be applied where such treatments would make stands susceptible to pest-caused damage levels inconsistent with management objectives.”

We believe that in many cases clearcutting can replace natural fire in removing diseased stands and replacing them with new mixed species stands of more disease and insect resistant species. A good example is a root rot and spruce budworm prone grand fir, Douglas-fir climax stand that has replaced a ponderosa pine or Western larch stand. By harvest and replanting, a more disease and insect resistant stand can be established.

156 PESTICIDE USE AND DISPOSAL IS A CONCERN.

COMMENTS INCLUDED:

“Less spraying of brush and road side weeds mean more wildlife.”

“I have always opposed broadcast spraying of chemical pesticides and herbicides. Along with air pollution, I blame the spraying of our fields and forests with the rapid decline of the birds and small mammals.”

“Spraying trees is a good idea if trees are infested with insects. We may lose a few birds but they will be back. Our trees in our yard are sprayed regularly, we still have birds in our yard & they raise their young here too.”

“More focus on bird habitat might decrease spruce budworm and associated insect infestation.”

“Herbicide sprays are destroying mulch and soil building.”

“I urge that the use of herbicides be eliminated, as they destroy many species of native vegetation, regardless of their desirability from a commercial timber standpoint.”

“The DEIS does not state whether there are any hazardous waste disposal sites on the Forest and describe how these are to be managed.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0063, 0540, 0577, 0579, 0582, 2785, 3270, 3588, 3911, 3991, 0018S, 2242S

FOREST SERVICE RESPONSE:

Any pesticide use will be subject to a forest environmental analysis tiered under the Regional Vegetation Management EIS and program. We have no evidence of any damage to wildlife or birds with any of the pesticides proposed for future use. There has been no herbicide use on the forest for several years pending completion of the Regional Environmental Impact Statement on the topic. Proposed herbicide use on this forest would be on a very small acreage to deal with competing vegetation in a few selected timber harvest units and with noxious weed infestations.

We know of no toxic waste disposal sites on the forest. If anyone knows of one we would like that information so we can take action to properly dispose of the material.

SOILS

157 THE ALTERNATIVES WILL REDUCE SOIL PRODUCTIVITY AND INCREASE EROSION.

COMMENTS INCLUDED:

“The Chelan, Entiat, and Wenatchee basins are described as having very thin “A” soil horizons. Because this soil layer is so thin, any additional surface erosion above background could constitute a serious loss of nutrients and reduction of site productivity.”

“My major recommendation is that specific remedial and regulatory actions be incorporated in all alt. to commence immediately. Almost every other mistake can be corrected within a 100 years or so. But with top soil it is a case of ‘he who hesitates is lost’ and irretrievably lost for a very long time.”

“If more than twenty percent of an activity area is compacted, reevaluation will be necessary. What degree of compaction is required? Will actual measurements of degree of compaction be made or will it be assumed that any paths of heavy machinery will cause compaction? Are cumulative effects of past management accounted for in these areas.”

“Is there a management requirement for soil erosion?”

“See page II-51, Delivered Sediment Levels: I am opposed to all increasing rates of erosion.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0066, 0076, 0579, 0882, 1681, 1952, 1981, 2026, 2132, 2723, 2725, 2731, 2820, 2836, 2876, 2879, 3045, 3067, 3083, 3103, 3239, 3250, 3750, 3911, 3913, 4235, 4298, 4410, 4453, 4485, 4493, 0084S

FOREST SERVICE RESPONSE:

No alternative considered will intentionally reduce soil productivity. The National Forest Management Act (NFMA - sec. 6C) requires plans be developed in accord with the Multiple-Use Sustained Yield Act of 1960. The NFMA further requires regulations be developed to ensure there will not be “substantial and permanent impairment of the productivity of the land” (sec. 6g. 3c). These requirements are specified in the Regulations (219.14 b1). Standards and Guidelines apply Forest-wide and have been developed to maintain soil productivity and minimize erosion. The Forest-wide Standards and Guidelines are located in Chapter IV of the Forest Plan. In addition to the Forest-wide Standards and Guidelines the Forest also uses the Regional Guidelines for Best Management Practices (BMP’s - and this information is included in Appendix J of the FEIS.)

Activities that create impacts which exceed the Forest-wide Standards and Guidelines will require development and implementation of a rehabilitation plan that will restore the site to a satisfactory condition. Past management activities can cause cumulative impacts, (e.g., soil compaction) so additional monitoring may be needed to identify these areas to avoid or prevent unacceptable soil degradation

158 CONCERN WAS EXPRESSED ABOUT USING THE UNIVERSAL SOIL LOSS EQUATION (USLE) TO DETERMINE SEDIMENT YIELDS. THE EQUATION MAY NOT GIVE ACCURATE SEDIMENT PREDICTIONS BECAUSE IT WAS DEVELOPED ON AGRICULTURAL LANDS AND USED ON MOUNTAINOUS LANDS.

COMMENTS INCLUDED:

“The amount of siltation estimated for the various alternatives is highly questionable from the agricultural soil loss model used. I could find no experimental verification of the modified agricultural model in the DEIS, yet the timber management and road-building prescriptions of the final plan should rely upon an accurate siltation model if they are to minimize damage to fish habitat. For this reason the Forest Service must begin studies of the accuracy of its modeling methods, estimating the error statistics of the methods, and should set a deadline (preferably before the release of the final plan) by which a final modeling method must be chosen and documented.”

“*Inaccurate sedimentation estimates* The Forest Service used the universal soil loss equation (USLE) as its model for predicting sedimentation resulting from the proposed forest plan.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0342, 0579, 0580, 0582, 2201, 3085, 3750, 4485, 4493, 4495, 4498

FOREST SERVICE RESPONSE:

Several equations and models were used to predict soil erosion. Each one has some limitation depending on the amount and quality of data available. It was not the intent of the models to show exact amounts of soil loss or sediment delivery. But they were designed to make comparisons between one alternative and another, so that relative risks of implementing different practices could be evaluated. The process used by this Forest are described in a separate document titled “Delivered Sediment Coefficients”, which was prepared by Phillip McColley, Forest Soil Scientist (February 1985).

The models that were used are based on certain principles that affect soil erosion. The principles can be applied to a variety of conditions. The magnitude of any of the variables depends upon local conditions. Knowledge of the local conditions is more critical for predicting erosion and sedimentation than the model per se.

Soil erosion is only one part of predicting sedimentation. The erosion models are used for that part. Sedimentation depends upon the amount of eroded material that is delivered to the streams. Estimating the delivery factor requires additional knowledge and assumptions. The assumptions used are on file at the Supervisor’s Office in Wenatchee, Washington. (Also refer to Appendix B of the FEIS for a summary of the sediment yield analysis process used in Forest planning.)

159 THERE WAS CONCERN THAT LANDS UNSUITABLE FOR TIMBER REMOVAL ARE NOT IDENTIFIED.

COMMENTS INCLUDED:

“DEIS, page III-80, soils. Maps depicting locations of special concern soils areas (i.e. mass wasting areas, degraded areas) would be helpful in comparing past management with current and proposed conditions.”

“Detailed soil surveys will be used “where available” in project planning (plan IV-98). Since the general soil surveys were stated not to be adequate for project planning, what soil analysis will be used for project planning until detailed surveys can be made available.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0616, 2774, 2820, 2888, 3191, 3239, 3256, 3710, 3911, 4485, 4495, 9034, 9093

FOREST SERVICE RESPONSE:

Lands unsuitable for timber harvest because of stability problems (Class V stability hazard) are identified and shown on maps (in the Supervisor’s Office). A total of 18,700 acres of forested land were identified on the Wenatchee Forest. Other lands that are unsuitable for other reasons are also mapped. These maps are also located in the Forest Supervisor’s office in Wenatchee, Washington.

The acreages of unsuitable lands are shown in tables, in Chapters II and IV of the Forest Plan, and in Chapter III of the FEIS.

Some areas are very small, less than 5 to 10 acres, and are not shown on a map. In such cases, their features are described so they can be located and excluded from specific timber sale projects by an interdisciplinary team. Two physical conditions of the land are used for determining unsuitability for timber harvest. These are: lands where there is not reasonable assurance of successful reforestation in five years, and lands where technology is not available that will ensure timber production without irreversible damage to soils, productivity, or watershed conditions (National Forest Management Act (NFMA) sec. 6g. Ei and ii; Regulation 219.13b (1) iii and iv). Only lands with a high probability of significantly increasing landslides are considered unsuited because of the potential for irreversible damage.

***160 CONCERN WAS EXPRESSED ABOUT THE AMOUNT OF DELIVERED SEDIMENT PRODUCED BY SOME OF THE DIFFERENT ALTERNATIVES. AND SOME WERE CONCERNED ABOUT THE AMOUNT OF DELIVERED SEDIMENT PRODUCED IN THE DIFFERENT DEC-
ADES FOR THE PREFERRED ALTERNATIVE.***

COMMENTS INCLUDED:

“DEIS, table S-2, page S-8, summary of results relating to planning problems, the sediment increase index shows increases in all alternatives. Please explain why the planning premise is not the reduction/elimination of water quality degradation. It seems that with better technology and management techniques that land managers would be able to reduce sedimentation.”

“The preferred alternative has a nearly five % increase in sedimentation over natural levels for the first five decades, yet it is stated that state class AA water quality standards will be met. The anti-degradation policy of Wash. State (chapter 173-201-035 (8) WAC) provides that beneficial uses shall be protected allowing no water quality degradation which would interfere with existing beneficial uses.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0061, 0342, 0579, 0580, 0582, 2026, 2073, 2078, 2132, 2201, 2723, 2731, 2772, 2820, 2945, 3085, 3103, 3205, 3256, 3550, 3632, 3750, 3862, 3911, 4242, 4471, 4485, 4493, 4495, 4498, 4511

FOREST SERVICE RESPONSE:

It is difficult to predict with certainty how activities carried out under each alternative will affect local water quality conditions. Water quality conditions include many factors, most of which interact, including such parameters as sediment, temperature, dissolved oxygen, biochemical oxygen demand and pH. Natural systems are too complex for completely accurate predictions given our present state of knowledge. Another complicating factor is that the Forest planning process requires analysis of relatively large land units and complex treatments for decade-long periods. The ForPlan level of analysis tends to mask site-specific effects encountered for individual watersheds.

In the case of sediment, yield estimates were developed as part of the information used to determine the relative risk between alternatives. A systematic approach was used to develop estimates of increased sediment yield from management activities (timber harvest activities and associated road construction) in order to indicate trends and to compare alternatives. These yield estimates do not represent absolute quantities of sediment. This modeling effort was just one of the tools the Forest used in the analysis leading to a reasoned choice among alternatives. Additional information on the sediment modeling process may be found in Appendix B of the FEIS.

As stated in Chapter IV, a basic goal of the Forest Plan is to manage watersheds in a manner that maintains or improves overall water quality and fish habitat conditions on the Forest. The FEIS recognizes that, on a site-specific basis, these values are subject to risk due to management activities. In the Final Forest Plan, the Forest-wide Standards and Guidelines for protection of water quality, including Best Management Practices (see Appendix J of the FEIS), have been revised to strengthen and clarify management direction. A set of Forest-wide Standards and Guidelines for riparian area management has been developed, which include measurable standards for sediment. Forest-wide direction for monitoring water quality and fish habitat in Chapter V of the Plan has been improved.

Since analysis at the Forest planning level tends to mask the site specific effects encountered for individual watersheds, more detailed analyses of significant parameters will be conducted at the project level using the Standards and Guidelines in Chapter IV of the Forest Plan. Such analyses will include modeling on a watershed basis using project-specific information such as land types, project location, road design features, and mitigation measures. Past management activities within the watershed will be considered as well as proposed activities. These analyses will more closely predict the effects of activities on individual watersheds, providing information needed to evaluate project effects in regard to water quality standards and fish habitat objectives. The more detailed analysis performed at the project level will help to identify activity timing, location, and mitigation needs which will limit sediment increases to acceptable levels.

161 CONCERN WAS EXPRESSED THAT REHABILITATION OF DEGRADED SITES WAS NOT BEING DONE RAPIDLY ENOUGH, AND THAT SOME ACTIVITIES WERE NOT BEING CONSIDERED THAT CONTRIBUTED TO SITE DEGRADATION.

COMMENTS INCLUDED:

“I found it interesting the amount of trails open did not seem to effect your figures on erosion, moreover, they seem to be affected by timber activity.”

“In the course of an inventory (1978-1979) of degraded acres on the WNF, 143 sites were listed as needing rehabilitation. These sites were termed significantly damaged and eroding. Can rehabilitation really be accomplished on these sites? Since this survey was not completed, one wonders how extensive are the acres of degraded sites. How soon will the survey of degraded sites be restarted and what progress can be made on rehabilitation of all presently degraded sites in the next 10 years.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

1952, 4410, 4485

FOREST RESPONSE:

The amount of soil erosion from the trail systems locally can be very significant, however, Forest-wide it is really not significant when compared to the amount of ground disturbance created by road construction or timber harvest. Also, when translated to total acres affected, all the trails on the Forest account for a very small percentage of the entire Forest.

Part of the degraded site inventory is more than ten years old now, so it is appropriate that the listed sites (but non-rehabilitated sites) be reviewed to see if they are still creating problems, or if the sites have rehabilitated naturally over time. This work began in the 1989 field season. Furthermore, field crews are being instructed to identify and record on a WIN form (watershed inventory needs) any sites that they feel need to be rehabilitated. Some of the sites identified in the 1978-79 inventory have recovered naturally and were taken off the degraded inventory listing. Rehabilitation work can be very expensive, and the progress of this work has been limited because of the availability of funds.

AIR

162 AIR QUALITY IS AN IMPORTANT RESOURCE FOR WHICH THE FOREST SERVICE HAS MANAGEMENT RESPONSIBILITY BUT THIS IS NOT EMPHASIZED IN YOUR PLANNING PROCESS. WE WANT YOU TO ENSURE THAT MANAGEMENT OF THIS RESOURCE RECEIVES APPROPRIATE ATTENTION. WE WANT YOU TO MAINTAIN OR IMPROVE THE QUALITY OF THE AIR AFFECTED BY THE MANAGEMENT OF THE WENATCHEE NATIONAL FOREST.

COMMENTS INCLUDED:

“In general, the discussion included in the DEIS and the plan adequately cover the state concerns”

“Finally, with the worldwide destruction of our forests, the level of global air pollution can only get worse.”

“The final and most basic point that the DEIS did not address was the very fundamental issue of how the loss of our trees effects the air.”

“The plan should address the problem of population control if it is to keep the air clean here. The amount of particulate matter and carbon dioxide released by slash burning is gross and unhealthy in a world where we must all share the same air.”

“The Health effects of wood smoke appear not to have been considered.”

“Another thing that greatly disturbs me is the eventual mortality of our forests from air pollution.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0286, 0424, 0579, 2791, 3067, 3088, 3588, 3911, 4494, 4495

FOREST SERVICE RESPONSE:

We have substantially revised and updated Chapter III, the Affected Environment, of the FEIS as it relates to the management of air as a resource.

There has been a significant change within the Forest Service in the direction for management of this resource since the release of the DEIS. The issuance of an Air Resource Management Handbook (FSH 2509.19) and a revision of the Forest Service Manual have emphasized the requirement for all Federal Land Managers to ensure they consider and manage air as a primary resource.

Statewide, PM-10 emissions from Forest Service prescribed burning are being reduced. This reduction occurs from a combination of fewer acres being burned and employing techniques to reduce emissions. On this Forest we are emphasizing increased utilization of wood fiber and decreasing consumption of large woody debris in prescribed fires by burning in the spring and burning under more moist conditions.

The Forest is concerned about the impacts of smoke produced by prescribed fires on human health. All applications of prescribed fire are conducted in compliance with the State Smoke and Visibility Management Plans in an attempt to avoid and minimize the impact on the public. Currently the Forest is participating in research on the effects of smoke on both fire management personnel and the public. Implementation of appropriate management practices as defined by this research, and other applicable research, will occur during the life of this plan.

The Forest objective is to manage our air resource in a manner that maintains or improves the quality of this resource. This will include compliance with the statutes included in the Clean Air Act, compliance with the guidance provided by the State of Washington, and compliance with the regulations issued by Local Air Regulatory Authorities. Our immediate priority is to develop a better data base on which to base our decisions, and to improve our interaction with all agencies and individuals involved in the management of our air resource.

LAND STATUS

163 CONCERN ABOUT THE "CHECKERBOARD" OWNERSHIP AND LAND MANAGEMENT IN THE CLE ELUM AND LITTLE NACHES AREAS.

COMMENTS INCLUDED:

"The Little Naches area is a very poor example of Forest Management. It is a disaster area. Thanks to our "good" neighbors-Burlington Northern et al."

"I believe that the checker board ownership presents a particularly serious problem. Plum Creek Timber company land is a particularly distressing case at present."

"Somehow I believe the FS should resist activities on private land that are clearly out of line with their management goals, for example, in granting of easements for road construction or pursuing land exchanges."

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

1, 2819, 4298

FOREST SERVICE RESPONSE:

The intermingled private lands in the subject areas might be best described as industrial forest lands. As such, their management is quite different than the management of National Forest System lands, which are managed for a variety of public benefits. While offensive to some, the management practices on these private lands are within the limits set by the Washington State Forest Practices Act and the State Shorelines Management Act.

Land exchanges are discretionary and depend on willing partners on each side as well as public support. The pros and cons are examined carefully before making the decision to proceed. There must be a clear indication that an exchange is in the public interest before it is made. Typically it is much easier to identify lands which seem desirable additions to public ownership than it is to identify public lands which should be traded to private ownerships.

Private land access across National Forest System Lands is guaranteed in federal law. When other reasonable access is not available, it is not within the discretion of the Forest Service to withhold access.

164 ROLE OF THE FOREST SERVICE IN HYDROELECTRIC PROJECT LICENSING.

COMMENTS INCLUDED:

"It is the Forest Service's duty to impose terms and conditions that will assure adequate protection for National Forest land from the harms resulting from hydroelectric development. *See Escondido Mutual Water Company V. La Jolla and Rincon Bands of Mission Indians*, 104 S. CT. 2105, 2114-15(1983). It is also part of the Forest Service's trust responsibility to the tribes to ensure that it exercises its duty to impose terms and conditions so that the tribes' treaty rights are protected. The Northwest Power Planning Council is in the process of developing a list of potential hydro sites with the least potential for

adverse impacts on other resources. Forest Service activities related to hydroelectric power should be coordinated with these efforts, p.III-6.”

“Please amend the section on hydroelectric energy development to include a statement regarding the U.S. Forest Service affirmative obligation to condition (approval of) hydroelectric projects on the adequate protection and utilization of the National Forest under section 4 (E) of the Federal Power Act. (See *Escondido Mutual Water Co. V. La Jolla Band of Mission Indians*, 104 S. CT. 2105” (1984)).”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0296, 0297, 0308, 0349, 0352, 0353, 0355, 0391, 0425, 0492, 0495, 0498, 0499, 0505, 0506, 0642, 0648, 0651, 0828, 0901, 1963, 1986, 1987, 2053, 2066, 2131, 2201, 2835, 2849, 3297, 3323, 3394, 3621, 3862, 4408, 4445, 4454, 4485,

FOREST SERVICE RESPONSE:

The Forest Service is aware of both the responsibility and the authority placed upon it by Section 4(e) of the Federal Power Act. The Wenatchee Forest’s District Rangers work directly with the Federal Energy Regulatory Commission, and the hydroelectric project applicant in assessing the impacts of each proposed project. They also work together in developing the terms and conditions identified in the 4(e) report for incorporation in the project licenses.

A statement identifying this part of the Forest Service’s role in processing hydroelectric license applications has been added to Chapter III of the FEIS.

165 DISPLAY OF EXISTING AND PROPOSED UTILITY CORRIDORS IN THE LITTLE NACHES/NACHES RIVER AREA

COMMENTS INCLUDED:

“We do not understand the “existing” corridor up the Little Naches Valley crossing the crest somewhere near Green Pass as shown on the map on p. III-5 of DEIS. Neither can we figure out the outrageous north-south segment in the vicinity of Chinook Pass that would presumably go through the William O. Douglas Wilderness and Mt., Rainier National Park.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

4477

FOREST SERVICE RESPONSE:

The map on page III-5 of the DEIS is in error. It reflects erroneous information from the 1986 Western Regional Corridor Study by the Western Utility Group. We have informed the group of the error. The map has been corrected in the FEIS.

166 CONCERN FOR COORDINATION OF THE ALPINE LAKES AREA LAND MANAGEMENT PLAN LANDOWNERSHIP DIRECTION WITH THE FOREST PLAN.

COMMENTS INCLUDED:

“The Alpine Lakes Plan contains a land ownership adjustment map. This map should be eliminated from the plan or changed to reflect the actual current situation.”

“The Forest should acquire all lands in the Icicle drainage. Did someone drop the ball on this one? I thought that the Icicle was going to be managed for recreational use, not sold for cabins. If the Alpine Lake Plan does not call for Forest purchase of the lands in the area, then it should be amended to do so.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

3879, 4266

FOREST SERVICE RESPONSE:

The Forest Plan incorporates the Alpine Lakes Area Land Management Plan (ALALMP). Therefore, the land ownership classifications and mapping in the ALALMP are carried forward in the Forest Plan intact. At this time, there is no basis for making changes.

The portion of the ALALMP which deals with landownership direction for the Icicle Creek drainage is supplemented by the Icicle Creek Composite. The composite gives project level direction for land acquisition in the Icicle Creek bottomlands. This includes the direction to acquire 867 acres of private land along Icicle Creek. The long term goal is to manage the existing National Forest lands, plus such private lands as may be acquired, primarily for public recreation. There is no intent that all private lands within the drainage be acquired or that the private land owners be prevented from developing their lands.

167 CONCERN FOR THE LANDOWNERSHIP CATEGORIES ASSIGNED FOR THE CHIWAWA RIVER, LAKE CHELAN, BUMPING AND TIETON VALLEYS.

COMMENTS INCLUDED:

“We were dismayed to review your map in the plan (P B-2) on land ownership adjustments especially the planned disposal of some of the finest low elevation forest lands. Why is Chiwawa River corridor in category V needing more study? This is not checkerboard, or on the edge of the Forest. It has significant public resources of old growth, W/S river potential, and fisheries. The shores of Lake Chelan, that are presently federal are termed “best” in private ownership, the same for areas in the Bumping, Rattlesnake and Tieton Valleys. What is the rationale for this? Much of remainder of the forest is in a “case by case” category including areas the preferred Alt has in roadless recreation status. Have you no sense of the tremendous public values on these lands? While lands fall into each category far more should be in II much less in IV and different lands in V.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

4477

FOREST SERVICE RESPONSE:

The Chiwawa River Corridor is covered by management prescription WS-1. This is the prescription for a Scenic River designation (Proposed). The landownership portion of the prescription requires a review of all possible ownership needs for meeting the goal of the prescription, hence the Category V classification. In the case of the Chiwawa, this would probably be a very simple and straight forward matter. It should not be inferred that any existing National Forest system land would become private. At the same time there would probably be no need to acquire the private lands in the drainage.

The lands along Lake Chelan, and the Bumping, Rattlesnake and Tieton Valleys which are in Category IV are those that are mostly other than National Forest ownership and/or are big game winter range areas which could be as well managed by the Department of Wildlife.

Much of the forest falls into Category III because it is compatible with the management prescriptions applied to these areas. This classification provides the flexibility to meet the resource management goals in these areas. This includes those portions of roadless recreation areas which are in a "checkerboard" land ownership pattern. Any potential exchange of land is preceded by extensive public involvement to ensure that public values and concerns are not overlooked. See Appendix B of the Plan for a complete description of the land categories.

***168 FEASIBILITY OF THE FOREST SERVICE ACQUIRING INTERMINGLED LAND.
DESIRABILITY OF ACQUIRING MINERAL RIGHTS WITH LANDS.***

COMMENTS INCLUDED:

"A discussion should also cover the feasibility of the FS acquiring intermingled land. This discussion should include FS policy on securing all mineral rights to any land acquired by purchaser in fee title -- or trade."

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0062, 0147, 0415, 0577, 0901, 1955, 2097, 2198, 2753, 2735, 2888, 3244, 3483, 4110, 4259, 4266, 4471, 9094

FOREST SERVICE RESPONSE:

The level of land adjustment planning in the forest plan process is described in the Land Ownership Classification Plan incorporated into the Forest Plan. This classification plan provides broad direction for the long term preferred ownership of lands within the forest. It does not attempt to define or direct specific changes of ownership by owner, priority, or means of making the adjustment.

It is not believed to be feasible or desirable for the Federal Government to acquire all privately owned lands within the Wenatchee National Forest boundary. Instead, the Forest Service will review opportunities for ownership adjustment on a case by case basis with full public involvement under the general direction set down in the Forest Plan. Most ownership changes are likely to be through land exchange.

Those owners with whom there are ongoing land exchange efforts are identified in the plan. These are the ownerships which presently, and in the immediate future, have the greatest likelihood of successful ownership adjustments. It is Forest Service policy of long standing to acquire the mineral rights in any fee title acquisition. If a landowner does not have the mineral rights, they are encouraged to acquire them and pass them to the United States with fee title to the land. Recent examples of this are the Pack River Co. acquisition in the then "Intended Wilderness" portion of the ALpine Lakes area and the ongoing exchanges with the Longview Fiber Co. In both cases the private landowner purchased the mineral rights in order to pass them on to the United States with the fee title.

As this is a national policy of long standing and the Wenatchee National Forest plan does not propose deviating from it, it was not felt necessary to discuss it in the plan.

169 NO MENTION OF LANDS MANAGED BY THE NATIONAL PARK SERVICE AND THE BUREAU OF LAND MANAGEMENT.

COMMENTS INCLUDED:

“This (land adjustment discussion) describes state and private inholdings but not intermingled and adjacent Federal lands. We believe it would be appropriate, to clarify the land patterns, to mention land managed by the National Park Service and the Bureau of Land Management.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

9094

FOREST SERVICE RESPONSE:

Our discussion and planning effort was limited to the intermingled and adjacent non-federal lands because their management has the most potential for creating cumulative environmental impacts which affect adjacent National Forest land, the occurrence of non-conforming uses, and increased management costs. The National Park Service and Bureau of Land Management lands are adjacent to, but not intermingled with the Wenatchee National Forest lands. They are federally owned, the management activities on them are compatible with the management of the adjacent National Forest lands, and there are no transfers of these ownerships in the offing. Therefore, we see no need to address these federal lands in the land adjustment discussion.

170 UTILITY CORRIDORS - ARE RESEARCH NATURAL AREAS EXCLUSION AREAS OR AVOIDANCE AREAS.

COMMENTS INCLUDED:

“In our review, we noted that the Wenatchee National Forest has designated Research Natural Areas as corridor exclusion areas. It is our understanding that the only types of areas that can be called exclusion areas are those having a statutory prohibition to rights-of-way for lineal facilities or corridor designation...we believe Research Natural Areas should be identified in the EIS as avoidance areas rather than exclusion areas.

LETTERS WITH COMMENTS ON THE SUBJECT INCLUDE:

4509

FOREST SERVICE RESPONSE:

We agree. We have changed the Standards in the RN-1 (Research Natural Area) prescription from exclusion to avoidance.

171 ENERGY - SMALL HYDROELECTRIC SITES:

COMMENTS INCLUDED:

“An explanation of the proposed small hydro-electric sites is warranted.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0579, 0828

FOREST SERVICE RESPONSE:

Detailed descriptions of project level activities are beyond the scope of this plan. However, for a brief description of these proposal see Chapter III of the FEIS.

MINERALS

172 THE PLAN DOESN'T APPROPRIATELY RECOGNIZE THE IMPORTANCE OF MINERAL RESOURCES, NOR DOES IT APPEAR THAT MANAGEMENT UNDER THE PLAN WILL ENCOURAGE AND FACILITATE MINERAL EXPLORATION AND DEVELOPMENT ACTIVITIES; AND, IN FACT, IT APPEARS THAT BECAUSE OF THE PLAN'S HIGHLY RESTRICTIVE MANAGEMENT APPROACH IT MAY ACTUALLY DISCOURAGE ANY INTEREST IN EXPLORING FOR OR DEVELOPING THE MINERAL RESOURCES ON THE FOREST.

COMMENTS INCLUDED:

“However, the document does not consider minerals as a valuable resource to be treated on par with other resources in the development of the forest plan, and ultimately on the land allocations.”

“An important issue to the Department (Washington State Department of Natural Resources) is access to land for mineral exploration and mine development. The Department is in support of protecting and improving the opportunities for mineral exploration when consistent with the protection of other resource objectives.”

“The information contained in the mineral section says claims would be withdrawn and acreage closed--why? Is it permissible to do this? We hope further consideration to the mineral areas will be given and allow “rockhounds” to continue their hobby. I don't understand the recurrent comment that access to locatable minerals will be restricted. The mining laws guarantee to right of reasonable access to mining claims.”

“Alternative E and F are anti-mining, and the other alternatives are not generous to the minerals category either.”

“You are ignoring or playing down one of the assets of the lands - the minerals.”

“The proposed plan will seriously suppress mineral exploration and development in those areas of highly restrictive management. We believe this is not, and should not be, the goal of the Forest Service.”

“While the plan acknowledges the right of access to Federal lands that have not been formally withdrawn from mineral entry under the mining laws, it, in fact, will create a tacit withdrawal by making access and operations excessively costly.”

“The Forest Service is not building encouragement for mineral discoveries into its plans. Instead of encouraging mineral activity, each alternative has emphasized highly restrictive management adjacent to wilderness areas. This is neither sound management nor in our National interest. Reopen wilderness areas to mining development.”

“We, the undersigned, strongly protest your proposal to withdraw 2,547 acres and to highly restrict 436,915 acres. We say enough is enough.”

“It is imperative that Forest Service policy is to protect the rights of miners, and to assist and encourage careful development.”

“In general, I oppose further restriction and withdrawals. Reopen closed areas. We enjoy prospecting, so please don't take away our rights. We are tired of more and more land going into wilderness, roads being closed, etc., and in general being harassed by the government. The proposed withdrawals are too drastic. We feel mining should even be permitted in wild rivers if justified. Swauk Pass highway will be highly restricted, but the public actually likes to watch the mining activity. I very much object to your proposed closures. The plan should allow and provide incentives to explore closed areas for minerals because the nation's well-being is vulnerable to the foreign control of non-domestic sources of minerals. The Wenatchee NF has mineral potential which has not been thoroughly explored, and that potential needs to be recognized. Only maximum land availability will give our nation a chance to minimize our critical mineral dependence on off-shore sources. We urge that you not apply highly restrictive management practices to mineral access. The Forest Service is not building encouragement for mineral discoveries into its plans. It appears there has been little consideration for the mining industry. We are dependent on foreign supplies of minerals; lets develop our own.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0047, 0232, 0287, 0296, 0297, 0299, 0308, 0342, 0349, 0352, 0355, 0391, 0425, 0492, 0495, 0498, 0505, 0506, 0543, 0546, 0582, 0642, 0648, 0651, 0829, 1303, 1950, 1963, 1986, 1987, 2066, 2098-2118, 2124, 2129, 2152, 2198, 2724, 2736, 2758, 2764, 2795, 2796, 2811, 2991, 2996, 3064, 3071, 3072, 3086, 3087, 3089, 3092, 3093, 3094, 3196, 3297, 3373, 3447, 3452, 3453, 3455, 3456, 3457, 3458, 3476, 3477, 3494, 3517, 3525, 3526, 3527, 3528, 3536, 3537, 3578, 3581, 3594, 3597, 3598, 3612, 3613, 3618, 3637, 3664, 3665, 3825, 3826, 3827, 3828, 3829, 3830, 3831, 3848, 3860, 3929, 3997, 3999, 4006, 4062, 4076, 4077, 4078, 4135, 4137, 4182, 4201, 4249, 4250, 4251, 4252, 4253, 4254, 4255, 4256, 4280, 4284, 4428, 4445, 4478, 4479, 4480, 4481, 4482, 4514, 4515, 4516, 4517, 4518, 4519, 4520, 4521, 4522, 4523, 4524, 4525, 4526, 4527, 4528, 4529, 4530, 4531, 4532, 4533, 4535, 4536, 4537, 4538, 4539, 4540, 4541, 4542, 4543, 4544, 4545, 4546, 4547, 9053, 9083, 9094

FOREST SERVICE RESPONSE:

Mineral resources received equal consideration with other resources in the development of this plan. The plan clearly recognizes the right of reasonable access to mining claims, mineral leases, and mineral permit areas. None of the alternatives call for a substantial amount of land to be withdrawn from entry under the mining and mineral leasing laws. The preferred alternative recommends 2,247 additional acres, or approximately 0.1% of the forest, be considered for withdrawal. Except for the existing withdrawals including wilderness, all other areas on the Forest are considered to be available for mineral exploration, and are available for development should valuable mineral resources be discovered. Our policy is to encourage and facilitate those activities even when such activities are being proposed in areas managed primarily for other resource uses.

The decision to manage lands as semi-primitive, roadless, non-motorized areas, or as other relatively protected areas, was made with a clear understanding that those areas will remain available for mineral exploration and development in an environmentally sensitive manner. If site specific environmental analysis shows a road in an unroaded area or motorized equipment in non-motorized areas is necessary for mineral exploration and development activities, such activity will be approved. The cost of operating in environmentally sensitive areas like those designated as semi-primitive non-motorized areas will probably be higher than it would be in those areas identified for a "general forest" management approach. Those higher cost are mostly due to the environmental sensitivity of the area, and are not due solely to the prescription under which the area will be managed. In addition, the cost of meeting the environmental restrictions attached to approved operating plans will be considered when determining if those restrictions are technologically, environmentally and economically reasonable (36 CFR 228.5 (a)).

Mineral resources have been recognized as a very valuable resource in our planning process. The Forest Plan gives more emphasis to the need for mining access and the need to minimize the number of new withdrawals proposed (see Chapter IV of the Plan). In this way, the plan better reflects our policy of encouraging and facilitating, in an environmentally sensitive manner, mineral exploration and development activities proposed for lands open to such activities.

173 MINERAL EVALUATION PROCESS AND TERMINOLOGY CONCERNS.

COMMENTS INCLUDED:

"Treatment of mineral potential is confusing due to a lack of clear statement of the terms and the methodology used."

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

9094

FOREST SERVICE RESPONSE:

The assessment of the mineral potential in Chapter III of the FEIS has been changed to more accurately reflect the mineral potential evaluation process. This not only should clarify the terms and methodology used, but also incorporated some of the public and agency suggestions.

174 COAL RESOURCE CONCERNS.

COMMENTS INCLUDED:

“The KCRA should be shown on Figure III-12”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

9094

FOREST SERVICE RESPONSE:

We did attempt to show the “known coal resource areas” here. Because there are only 106 acres of Forest land classified in this manner, it does not show up on the scale of map used in Figure III-12. However, this information is available for review on the leasable mineral classification maps available in either the Wenatchee Forest headquarters at Wenatchee or in the local BLM offices.

175 CONCERNS ABOUT DISPOSING OF THE MINERAL ESTATE THROUGH EXCHANGE OR SALES.

COMMENTS INCLUDED:

Areas identified for land disposal include much land which is valuable for coal, oil, and gas, geothermal, and hardrock leaseables.”

“An explanation as to how the determination that it would be in the best interest of the public to dispose of lands and whether the mineral estate would be reserved to the Federal Government would be useful to reviewers.”

“Future land swapping (trading of our mineral rights) is a concern.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

3860, 9094

FOREST SERVICE RESPONSE:

A statement about public interest and mineral resource evaluations for land exchange actions may be beneficial to those reviewing this plan. We have attempted to provide some information under the Minerals section in Chapter III of the FEIS. This information does not go into much detail about the evaluation process, but the evaluation is detailed and very comprehensive. This section does provide the appropriate references to be consulted for further information about the process. In any case, thorough evaluation of the mineral resources is done when a land exchange is proposed. The results of that evaluation along with the surface values and other objectives of the exchange are considered in determining whether the exchange is in the public interest and/or whether the mineral estate should be reserved. If land is exchanged out of public ownership, mineral rights are exchanged with it, just as mineral rights are acquired with the new land being added to the National Forest.

176 SUGGESTED MODIFICATION OF MINERAL TABLES IN CHAPTER IV OF THE DEIS.

COMMENTS INCLUDED:

“The tables on pages IV-79 through IV-85 are excellent; however, we feel they could be substituted by a table used by the Wallowa-Whitman National Forest and by adding the access categories used by the Beaverhead National Forest.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0596, 9094

FOREST SERVICE RESPONSE:

We have modified the Tables in Chapter IV of the FEIS. As you will note, we have not used exactly the same format as was suggested (the Wallowa-Whitman). However, our tables provide some additional information, which we feel will be useful for any reviewer’s analysis.

177 A SUGGESTION TO INCLUDE THE MINERAL RESOURCE POTENTIAL MAPS IN THE DOCUMENT ITSELF.

COMMENTS INCLUDED:

“The Mineral Potential Map located on Page III-89 of the DEIS should be enlarged to the same scale as the color alternative maps. The maps attached to your letter of July 18, 1986 were excellent. Maps of this kind included in the EIS are essential for those readers who wish to understand mineral resource potential, how these resources will be managed, and how this management is related to the management of other resources.”

“We request that the computer-generated maps which demonstrated proposed management practice on areas of mineral potential be included in the report. Mineral potential maps for each one of the Roadless areas would also be beneficial.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0596, 9094

FOREST SERVICE RESPONSE:

The referenced maps would be especially useful to those reviewing the plan, and we would like to be able to include such maps as part of the public documents. However, including this scale of map for all the resources of interest is cost prohibitive and, therefore, a decision has been made not to do so. They are available for use in the Forest Supervisor’s office in Wenatchee, Washington, and they can be generated at cost for those members of the public who request a copy.

178 OFFERS TO PROVIDE MINERAL RESOURCE DATA.

COMMENTS INCLUDED:

“We cannot provide input with regard to areas of mineral resource potential at this time. We are planning to provide you with this data in the future and hopefully will be able to compensate with quality” (U.S. Bureau of Mines).”

“Our Geology and Earth Resources Division Staff may have information on specific areas in the Wenatchee National Forest of mineral interest. Feel free to call Ray Lasmanis.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0342, 0596

FOREST SERVICE RESPONSE:

We appreciate the offers to assist us with mineral resource potential data, and it would have been especially nice to have that input for use in this FEIS. However, we also realize how limits on budgets and manpower can affect the ability to provide such input. Our planning process is a dynamic process, and we look forward to your input for use in amending, revising or updating this Forest Plan in the future.

179 CONCERNS ABOUT ENVIRONMENTAL IMPACTS OF MINING, THE GENERATION OF DANGEROUS MINING WASTE AND STATE REGULATORY AUTHORITY.

COMMENTS INCLUDED:

“Mine spoils may contain heavy metals. These potential sources of hazardous materials need to be identified and evaluated. If the evaluation determines there are solid or dangerous wastes present at these mining sites, disposal shall be in compliance with Chapter 173-303 and 304 (WAC).”

“Toxic materials commonly released by mining are arsenic, cadmium, cobalt, copper, iron, lead, manganese, mercury, nickel and zinc. Fish mortality can result from exposure to these metals in high concentrations, continuous exposure to low levels of the metals may produce chronic effects. You should require halting of any management activity that leads to violations of State water quality standards.”

“Page III-86 --As mentioned earlier, Hydraulic Project approval is required for any in stream prospecting activity. The Forest Service should recognize State authority to manage mineral activities in rivers.”

“Under mining activities, only past mining is discussed with no discussion of future activities such as road building and site disturbance for exploration or extraction. Even through these topics may be covered in separate, project-specific environmental documents, some generic impacts should be covered.”

“Page IV-128--The riparian zone is not appropriate for disposal of toxic mine tailing. Page IV-106--Impacts are described as temporary, however, coal mining operations often last for decades’. There is no discussion of what happens to the environment if a major portion of

the mineral potential areas are developed. This oversight violates NEPA, which requires a consideration of cumulative impacts. Impacts to lakes and ponds from mining activities are not address. Mining and cattle pollute our waters more than any other use.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0032, 0579, 0582, 2736, 2829, 3553, 3862, 9094, 0018S, 0183S, 1144S

FOREST SERVICE RESPONSE:

As noted in Chapter IV of the FEIS, mining can have environmental effects, but the Forest Plan is not designed to evaluate site-specific and project-level impacts. Mining-related activities are usually initiated by the mining industry, and industry’s interest in conducting such activities is highly dependent upon the supply/demand situation, the results of exploration and other factors. As a result we do not know specifically where, when or what type of mineral activities will be conducted. However, as specified by federal surface management regulations (36 CFR 228 regulations) the impacts of mining and using and/or generating hazardous or toxic materials in a proposed mining operation will be evaluated in an environmental analysis/environmental impact statement. This is completed when a plan of operation is received. Any approved plan will include a requirement to minimize impacts and protect the environment from any use or generation of hazardous or toxic materials. In addition, any operator who uses or generates such materials is required by law to meet all applicable federal and state requirements concerning such substances. Mining activities must also comply with the State water quality requirements and miners must secure a hydraulic permit from the State before operating within the high water line of streams and rivers.

180 A DISCREPANCY IN ACREAGE FIGURES.

COMMENTS INCLUDED:

“Page II-48--Withdrawal figure of 12,826 acres disagrees with numbers given in the accompanying table.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0582

FOREST SERVICE RESPONSE:

The apparent discrepancy is due to two factors. First, the 12,826 acres includes the total withdrawn area. However, the acreages reflected in the table are only those areas which have been identified as having a potential for the occurrence of locatable minerals, oil & gas, geothermal resources and coal. Secondly, the area identified as having potential for the occurrence of specific mineral resources can overlap, and that overlap is not identified in the table and narrative figures.

181 CONCERN ABOUT WATER QUALITY STANDARDS AND MONITORING AND EVALUATION OF THE PLAN.

COMMENTS INCLUDED:

“What are the standards for instream compliance; what will be measured? It would seem that this type of monitoring is superficial at the cost and using the methods listed. How much water quality monitoring is the mining company responsible for? Within what time period will a 10% increase in activity on active claims be evaluated. Is there a threshold level of surface disturbance in terms of area or magnitude or delivered sediment which should not be exceeded?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0579, 3553, 4485

FOREST SERVICE RESPONSE:

Mining operators are required by law to meet all State and Federal water quality standards, and are required to obtain any appropriate Federal and State hydraulic and discharge permits. The standards to be met, the monitoring and compliance requirements, and the parties responsible for ensuring the appropriate standards are met are established at the time mineral-related activity is proposed and evaluated but before it is approved. In most cases, the mining company is responsible for conducting the monitoring activities, while the administering agency is responsible for ensuring that monitoring is conducted in the appropriate manner. The monitoring and evaluation program in Chapter V of the Forest Plan is designed to ensure that on-the-ground administrators perform the appropriate compliance checks as required by 36 CFR 228.7 and other regulations. Those compliance checks should ensure the objectives of the Forest Plan are met. This plan has no established threshold level of surface disturbance in terms of areas or delivered sediment. Any such standards will be established as part of the approval process for the plan of operation. It is intended that if the mining-related activity within a management area increases more than 10% in any one year, the effects of that activity will be evaluated to ensure the activity being conducted is in compliance with the objectives of this plan.

182 CONSIDERING THE COST OF ENVIRONMENTAL PROTECTION IN MINING PLAN APPROVAL.

COMMENTS INCLUDED:

“Should the cost of reclamation or environmental protection be an important factor in approving mining-related activities.”

“Although costs of operating must be considered by mining companies before undertaking an operation, why is it the responsibility of the Forest Service to assure them that any activity may be conducted at a profit. If safeguarding the environment costs a certain amount, why must an operating plan be watered down so that costs to the operator are less than costs to the environment?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

4485

FOREST SERVICE RESPONSE:

36 CFR Part 228.5 (a) requires the authorized officer to “analyze the proposal, considering the economics of the operation along with the other factors in determining the reasonableness of the requirements for surface resource protection”. It further states that “all operations shall be conducted so as, where feasible, to minimize adverse environmental impacts” (36 CFR 228.8). The importance of protecting the environment and the cost of providing that protection are aspects of operating that both the Forest Service and the mining industry well recognize. However, we also recognize that mineral resources are very important to the well-being of our nation and, therefore, we have the responsibility for encouraging and facilitating mineral activities. We have the responsibility of balancing the nation’s need for minerals with the need to protect the environment. To do this we must be technologically, economically, and environmentally sensitive when determining the reasonableness and the extent of environmental protection requirements to be required when approving operating plans.

183 MINING MAY BE NECESSARY, BUT IT SHOULD BE STRINGENTLY CONTROLLED AND HEAVILY CONSTRAINED.

COMMENTS INCLUDED:

“Mineral development would be possible if it doesn’t impact any other use.”

“Mining activities need to have heavy constraints applied to protect soils and aesthetics.”

“Mining should be prohibited, and our resources should be saved for the future.”

“Mineral exploitation represents a blatantly, inherently unsustainable industry and the practice should not be allowed.”

“Are you allowing a lot of mineral activity because it gives dollars to the Federal Government, or because the nation needs the resources.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0040, 0062, 0147, 0185, 0561, 0577, 2131, 2156, 2724, 2729, 2732, 2798, 2849, 2996, 3394, 3989, 4449, 4454, 9092

FOREST SERVICE RESPONSE:

The availability of mineral and energy resources within the National Forests affects the development, economic growth and defense of the Nation. Because of this importance and several laws, it is the policy of the Forest Service to encourage and facilitate the orderly exploration, development and production of mineral resources. As stated in Chapter IV of the Forest Plan the objective is that new mineral resources be discovered and a viable and healthy minerals industry is maintained. Over-restriction could discourage interest in conducting mineral exploration and development activities. However, it is also Forest Service policy to ensure that mineral activities are conducted in an environmentally sound manner, and to ensure that lands disturbed by mining activity are appropriately reclaimed for other productive uses.

184 NO MINING IN WILDERNESS SHOULD BE ALLOWED.

COMMENTS INCLUDED:

“Any mineral development in wilderness areas should be categorically forbidden.”

“We would prefer that mining not be allowed in wilderness.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0047, 2732, 2996

FOREST SERVICE RESPONSE:

Mining in designated wilderness areas is permitted only when valid existing rights to mine have been established prior to December 31, 1983 or prior to the date an area was designated as wilderness under a subsequent wilderness bill. This would occur when a valuable mineral deposit had been discovered and claims were located prior to the date of withdrawal, or when a mineral lease or mineral permit had been issued prior to the withdrawal as wilderness. Prior to approval of any mining activities, however, valid existing rights to mine will have to be confirmed. If valid rights exist, to not allow such activity would be contrary to the law and a form of “taking” of one’s legal rights.

Even though mining occurs only when prior existing rights exist, the Wilderness Act does provide for prospecting activities, and actually directs the U.S. Geological Service and U.S. Bureau of Mines to determine the mineral values in wilderness areas by conducting planned and recurring mineral surveys. Refer to Appendix E, Wilderness Management, of the Forest Plan for a discussion of mining related activities within Wilderness areas.

185 WE SHOULD PROVIDE FOR RECREATIONAL MINERAL COLLECTING, PANNING, SLUICING, AND DREDGING.

COMMENTS INCLUDED:

“Gemstone and specimen crystal areas should be withdrawn from mineral entry, but managed for public recreation use.”

“We would support alternative A or C provided further attention is given to assuring road access is maintained to the rock and mineral collecting localities. Many members are elderly or physically unable to hike long distances.”

“If there is an agreement to further study and possibly change Alternative C to ensure access to collecting areas, then we will support Alternative C.”

“If you are going to withdraw parts of the forest, I suggest gold placer areas be set aside for everyone to use.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0225, 0239, 0240, 0606, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2124, 2152, 2198, 2736, 2811, 2821, 2991, 3064, 3071, 3072, 3086, 3087, 3089, 3092, 3093, 3094, 3196, 3372, 3447, 3451, 3452, 3453, 3454, 3455, 3456, 3457,

3458, 3476, 3477, 3494, 3506, 3517, 3525, 3526, 3527, 3528, 3536, 3537, 3578, 3594, 3597, 3598, 3612, 3613, 3618, 3637, 3664, 3665, 3746, 3825, 3826, 3827, 3828, 3829, 3830, 3831, 3848, 3881, 3929, 3997, 3999, 4006, 4033, 4062, 4076, 4077, 4078, 4135, 4137, 4182, 4201, 4249, 4250, 4251, 4252, 4253, 4254, 4255, 4256, 4280, 4284, 4302, 4428, 4465, 4478, 4479, 4480, 4481, 4482, 4514, 4515, 4516, 4517, 4518, 4519, 4520, 4521, 4522, 4523, 4524, 4525, 4526, 4527, 4528, 4529, 4530, 4531, 4532, 4533, 4535, 4536, 4537, 4538, 4539, 4540, 4541, 4542, 4543, 4544, 4545, 4546, 4547, 9053, 9083, 9090

FOREST SERVICE RESPONSE:

The plan does not propose that any specific areas be withdrawn for recreational mineral collecting, panning, sluicing and dredging activities. It is recognized that there is a demand for such activities, and the Forest-wide Standard and Guideline for minerals provides for such opportunities (see Chapter IV of the Forest Plan). This Standard and Guideline does not, however, require that areas be withdrawn for such purposes. If after the plan is implemented specific problem areas are identified and the demand justifies a withdrawal for such purposes, there are provisions for amending or supplementing the plan to accommodate such proposals.

186 THERE ARE CONCERNS THAT THE MINERAL RESOURCES HAVE NOT BEEN ADEQUATELY INVENTORIED FOR THIS PLANNING EFFORT.

COMMENTS INCLUDED:

“In congressional instruction all lands were to first have a mineral survey, and this was not done. If lands have history of mining, they were to be set aside for minerals and, therefore, the proposals are without legal justification.”

“A real mineral survey of the whole area has not yet been done and you show that there is not significant amounts of minerals. Things should be left as they area until more mineral study has been done.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0047, 0666, 3778

FOREST SERVICE RESPONSE:

It is true that on-the-ground mineral surveys supplemented by surface and subsurface sampling were not done. We have neither the money nor the man-power to conduct such surveys. Normally, exploration is conducted by the mining industry, and our objective is to encourage such activities, not to conduct the mineral resource data gathering activities ourselves. Ultimately, we believe that the exact nature, extent, and location of any new resources will be determined by industry through exploration under the 1872 Mining Laws. We, however, have completed a mineral evaluation using all available pertinent mineral resource occurrence and geologic data, this included U.S. Geological Survey, U.S. Bureau of Mines and State sources of information. Through that evaluation areas having a potential for the occurrence of locatable mineral resources have been identified. In addition to the locatable mineral resource areas, the BLM has identified areas having potential for the occurrence of leasable mineral resources (coal, oil and gas, geothermal). The Forest has completed a minerals materials inventory which identifies where those resources occur. We feel that these evaluations adequately serve our needs for this planning effort, and our evaluation meets the land management planning requirements for mineral evaluations.

Chapter II of the Forest Plan addresses the information needs for mineral resources. As new mineral information becomes available through our own efforts or the efforts of the mining industry, it can be used to supplement or amend our land management plan appropriately. Under this Forest Plan very little new area would be withdrawn from mineral exploration and development activities. It is our intention to encourage those interested in conducting mineral information gathering activities.

187 HOLDEN TAILINGS ARE OF CONCERN.

COMMENTS INCLUDED:

“Holden tailings are an eyesore and a source of air pollution, and I would encourage reclamation without restricting mineral rights.”

“Reclaim and reforest Holden tailings. I would favor any plan that would stabilize Holden tailings.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0293, 0494, 2795, 3297

FOREST SERVICE RESPONSE:

Money has been appropriated from the Department of Agriculture fund for hazardous waste cleanup. The reclamation of the area is already underway and is to be completed within the next 3 years.

188 T & E SPECIES HABITAT SHOULD BE PROTECTED FROM THE IMPACTS OF MINING.

COMMENTS INCLUDED:

“Threatened species habitat should be withdrawn, or no surface occupancy should be allowed. We suggest that operating plans definitely be rejected if there is an unavoidable conflict with endangered species habitat.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0582, 4477

FOREST SERVICE RESPONSE:

By law, threatened and endangered species are to be protected. A withdrawal is not necessary to ensure appropriate protection is provided. If mining activities are proposed and a threatened or endangered species will be affected, the impacts on the species will be analyzed. A U.S. Fish and Wildlife Service consultation process will be completed, and a decision will be made on whether the activity should be approved. If approved, stipulations and reclamation requirements will be made part of the approved operating plan to ensure appropriate protection is provided. If impacts to a threatened or endangered species or its habitat cannot not be prevented or appropriately mitigated, the mining activity would not be approved.

189 EXPLORATION ACTIVITIES COMMENTS

COMMENTS INCLUDED:

“Exploration is not destructive.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0287, 2129

FOREST SERVICE RESPONSE:

Most mineral exploration activities can be conducted in an environmentally sound and safe manner. The mining industry is willing to take extra precautions to ensure the environment is appropriately protected. We appreciate comments that recognize this fact, and recognize the important role that exploration plays in our efforts to know where and what type of minerals occur on our public lands.

190 POSITIVE COMMENTS.

COMMENTS INCLUDED:

“I feel it addresses the mineral rights and claims well. The Interaction With Other Resources section of the DEIS (page III-153) was especially useful.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

2756, 9094

FOREST SERVICE RESPONSE:

We appreciate positive comments which identify especially useful or beneficial parts of this document

191 SUGGESTED MITIGATING MEASURE

COMMENTS INCLUDED:

“Page III-138, paragraph 1. Another mitigation possibility is to restrict permitted mining to certain seasons.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0582

FOREST SERVICE RESPONSE:

We appreciate the suggestion, and we will be using such a mitigating measure when a seasonal restriction is reasonable and necessary. Mitigating measures are discussed in Chapter IV of the FEIS.

192 THE FOREST SERVICE DOES NOT HAVE THE AUTHORITY TO WITHDRAW LANDS.

COMMENTS INCLUDED:

“The National Forest Management Act of 1976 does not give the Forest Service authority to withdraw mining rights from NF lands. It takes an Act of Congress to withdraw those rights. I understand that the USFS only has jurisdiction on surface rights and not mineral rights as far as management goes.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

3881

FOREST SERVICE RESPONSE:

Withdrawals of public lands are made through the Secretary of Interior who has the authority to withdraw public lands from entry under the mining and mineral leasing laws. The Forest Service has the responsibility to manage the surface resources. If existing laws and regulations will not provide appropriate protection for sensitive resources, the agency may decide that a withdrawal is in the public's interest and would recommend the Secretary of Interior establish a withdrawal. This Forest Plan will not, by itself, result in the establishment of any withdrawals.

193 CONCERN ABOUT THE EFFECTS THAT MINING MAY HAVE ON THE LITTLE WENATCHEE AND WENATCHEE RIVERS, AND ON LAKE WENATCHEE.

COMMENTS INCLUDED:

“I believe mining on the Little Wenatchee would have a disastrous effect on the water quality of the river as well as on Lake Wenatchee and possibly the Wenatchee River as well. There are numerous examples where mining, leaching and refuse have destroyed the local environment as well as the aquatic and plant life.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0059S

FOREST SERVICE RESPONSE:

Mining operators are required by law to meet all Federal and State water quality standards, and any approved operating plan will include provisions to ensure those water quality standards are met. (Refer to Chapter IV of the FEIS and to Chapter V of the Forest Plan.)

ROADS

194 THERE IS CONCERN ABOUT THE EFFECTS OF ROAD CLOSURES.

COMMENTS INCLUDED:

“What we don’t like to see are iron gates and the humps in the roads that keep us out.”

“The Forest-wide Standards and Guidelines for road development and management do not adequately recognize and protect wildlife values.”

“Road mileage should be minimized, with all roads closed to public access.”

“Get rid of those.....gates unless they restrict everyone, including the FS. No one (private individual or concern) should be able to control access by the general public over public land over roads or trails constructed wholly or in part with public funds.”

“I’m sure the public i.e. hunters, fishermen recreationists wouldn’t mind the road construction so much if the powers that be would also develop a plan to bar road accessibility after the timber harvest is complete.”

“Keep the roads open to rock collecting sites. The closing of roads would create a problem for a lot of people who are not able to get out and hike miles to some areas.”

“We strongly object to the proposal to leave unused roads open except where clear resource conflict can be proven. We suggest that the reverse should be true. All roads should be closed unless no conflict can be proven.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0049, 0062, 0143, 0232, 0325, 0363, 0386, 0429, 0582, 0588, 0610, 0748, 0789, 0896, 1118, 1300, 1504, 1939, 1940, 1960, 2054, 2114, 2124, 2131, 2530, 2753, 2779, 2782, 2900, 2913, 2961, 3158, 3255, 3256, 3363, 3371, 3372, 3375, 3398, 3642, 3686, 3746, 3796, 3860, 3936, 3991, 4104, 4153, 4186, 4263, 4271, 4280, 4406, 4423, 4425, 4434, 4435, 4475, 4485, 4503, 9084,

FOREST SERVICE RESPONSE:

In response to the public comments, the road closure statement in the Forest-wide Standards and Guidelines has been changed. All new roads constructed will be closed unless the project analysis documents the need for continued public motor vehicle access. Unless there is a reason to close them, existing roads open to the public will remain open. The implementation of this standard and guideline is expected to result in about the same amount of public access by automobile as is currently available. Timber sale roads will remain open for firewood removal as appropriate. Nothing in this policy is intended to abridge the access rights of miners that are provided for under law. See Chapter IV, Standards and Guidelines, of the Forest Plan for a detailed discussion.

“Several of the alternatives should have shown a non construction option for the road. By having only one alternative which does not allow the road to be built, the outcome is heavily weighted in favor of construction. This is in violation of NEPA.”

“In another ill-advised provision of the Draft Plan, the Wenatchee National Forest proposes to build a logging road over Naches Pass. In view of the natural and historical values in Naches Pass, we are also proposing to Congress the designation of a Naches Pass National Monument to be administered by the National Park Service.”

“No log haul road should be built in Naches Pass. Such a road would not only damage this old pioneer trail, but would also hurt the Pacific Crest Trail..”

“I am categorically against the construction of Naches Pass road in any form and definitely against the Forest Service sharing in the cost of construction.”

FOREST SERVICE RESPONSE:

Public comment on this potential project was heavily opposed. The Forest Service sees no need for the construction of the Naches Pass Road so there is no proposal in the Forest Plan or FEIS for the project.

In 1982 in response to a request by Burlington Northern to build a log haul road near Naches Pass, the Forest Service Prepared the Naches Pass Final Environmental Impact Statement (FEIS). At that time, the Regional Forester selected Alternative # 1. See Page 13 of The Naches Pass FEIS.

“The decision on the need for a tie road, as well as the decision concerning Forest Service sharing in the road for commercial haul and public use, would be deferred until the National Forest Plans for the respective areas are completed. These plans would make the land allocation decisions for the areas involved in the proposed project. A decision would then be made on the Naches Pass Road proposal based on the land allocations.”

With the approval of the Forest Plans for the Wenatchee and Mt. Baker Snoqualmie National Forests, the Forest Service will have allocated the lands in this area. Those land allocations would not prohibit the construction of the Naches Pass road. However, the Forest Service has no need for the road and does not plan to construct such a facility for management purposes. There is no current proposal to construct the road over Naches Pass by any of the private property owners. If and when there is one, the

project would be subject to the appropriate site specific environmental analysis. That analysis would consider a full range of alternatives from no road to one that is suitable for mixed public traffic. At that time, the public would have an additional opportunity to comment.

196 THERE IS CONCERN ABOUT ROAD CONSTRUCTION AND EFFECTS ON FOREST RESOURCES

COMMENTS INCLUDED:

“I am concerned in general about increased roading and a potential increase in timber harvest. The analysis itself states that “Roads generate most of the negative effects on water, soil, fish, and wildlife.”

“There should be access for personal recreation and logging. Road access is the only way for people who could not otherwise enjoy forest recreation.”

“We are particularly concerned about the increase in road construction proposed. These additional roads will reduce trail mileage, increase fishing pressure on fragile mountain lakes, increase sedimentation and eliminate the lower forested trails.”

“Private transportation, highly consumptive and wasteful, is to be phased out within the first two decades. By the end of the fifth decade, the public system will consist of the two shuttles, one each on Highways 2 and 97.”

“Of all forest management tools, roads are the most impacting. Each mile of road requires the destruction of four acres of wildlife habitat.”

“In reference to the pending plan, no new roads are needed, unless we are going to use these roads to destroy the forest.”

“The local residents see the danger of locked gates and roadless areas where only a few could ever see the land we use and enjoy so freely today.”

3992, 4061, 4069, 4074, 4081, 4133, 4145, 4149, 4150, 4153, 4154, 4170, 4181, 4186, 4200, 4205, 4208, 4210, 4213, 4214, 4241, 4242, 4243, 4245, 4257, 4263, 4264, 4270, 4293, 4296, 4312, 4416, 4417, 4418, 4425, 4427, 4434, 4444, 4445, 4446, 4447, 4449, 4453, 4455, 4465, 4466, 4471, 4474, 4477, 4485, 4493, 4494, 4496, 4498, 4501, 4503, 4510, 4534, 9004, 9022, 9034, 9065, 9074, 9091, 9092, 9094, 0091S, 0176S

FOREST SERVICE RESPONSE:

Many respondents to the Plan are concerned about the construction of additional roads on the Forest. There will be no program of road construction for roads construction's sake on the Forest. Two-thirds of the Forest is unroaded today and under the Forest Plan more than 50 percent of the Forest would be managed in an unroaded condition forever. All but an insignificant amount of the expected road construction will be to facilitate logging, which by law is one of the established uses of the National Forests. Helicopter and long-span cable yarding systems may be used in areas of the forest where roading impacts are unacceptable because of steepness of terrain, unstable soils, or very high scenic values. However, new road systems will continue to be needed to provide access for more economical logging methods in many areas of commercial forest land.

Approximately 75 percent of the total expected road mileage already has been built on the Wenatchee Forest. Road building practices employed for the last 30 years have had some impact on forest resources. However, Chapter III of the FEIS shows that, with some local exceptions, the Forest is in very good condition. Within budget limitations, the Forest Service is identifying and correcting those undesirable road-related impacts that have occurred because of past practices. The Standards and Guidelines and Monitoring Plan in Chapters IV and V of the Forest Plan have been developed with the intent of preventing future adverse environmental impacts and mitigating those that cannot be avoided. With this direction we believe that the remaining 25 percent of necessary roads can be constructed with much less impact.

It is an objective of the Plan to build the least amount of road necessary to accomplish resource objectives. Roads will be built at the lowest practical standard to minimize impacts on forest resources. All proposed road projects will be subject to the appropriate site specific environmental analysis with the opportunity for public review and comment.

197 THERE IS CONCERN ABOUT THE AMOUNT OF ROAD PER SECTION.

COMMENTS INCLUDED:

“Road density in the past has averaged 4 MI/SQ MI. Current roading practices will reduce this to 3MI/SQ MI on newly roaded lands (DEIS IV-92). However, because the remaining timber base will be on those lands of greater than average steepness, this reduction in road density may reflect a change in harvest method rather than roading method.....If by closing 50% of the roads we arrive at a road density of 3MI/SQ MI, then the road density just after logging is 6MI/SQ MI....Where is the error in these calculations ? Possible actual road densities are really higher than stated or the degree of road closure is not as high as stated.”

“We strongly recommend maximums of 0.2 MI/SQ MI in important wildlife areas and 1 MI/SQ MI elsewhere. On the next page, typical road densities proposed for currently unroaded areas are also high. In addition, even these numbers understate impacts if spur and dead end road mileage is not counted.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0582, 3205, 3255, 3963, 4485, 4493

FOREST SERVICE RESPONSE:

Logging road densities are for the most part determined by the location of the timber to be harvested and the yarding method to be used. The anticipated reduction in the existing road density of 3.75 to 3.00 miles per square mile is the result of the use of more advanced logging systems that can yard the timber (pull felled trees) for greater distances and therefore require fewer roads. All the road densities in the DEIS included both open and closed roads and included all permanent roads (including "spur" roads and "dead end" roads). Temporary roads built during a timber sale are required by law to be revegetated and returned to production.

It is our opinion that road density figures are useful for estimating potential environmental effects in a programmatic analysis such as a Forest Plan but that a site specific project analysis is a more appropriate method for making decisions on road management in a given area. Such analysis can consider other important factors including thermal and hiding cover, forage, species sensitivity, wildlife populations and habitat quality. It may be that 0.2 mile of open road is intolerable in key wildlife areas while more than 1.0 mile of primitive road would have no effect on habitat effectiveness in other areas. To reduce the open road density on the Forest to 1.0 mile per square mile would require the closure of 73% of the existing roads. Such a substantial reduction of public access seems unwarranted.

Road densities will be maintained at the minimum levels necessary to permit management of resources and to allow desired public access for appropriate multiple uses. New roads constructed for timber management will be closed after the project unless the environmental analysis shows a need for long-term public access. Wildlife needs will be carefully considered in that process.

FIRE

198 FIRE MANAGEMENT ACTIVITIES NEED TO BE SUITED TO THE THE SPECIFIC AREA ON WHICH THEY ARE BEING IMPLEMENTED. IN SOME INSTANCES PRESCRIBED FIRE NEEDS TO BE APPLIED AND IN OTHER SITUATIONS THE SUPPRESSION OF WILDFIRES IS NECESSARY.

COMMENTS INCLUDED:

"We ask that you add: "which maintain multi-layered, uneven-aged stands."

"These figures are very close to your current program. This appears to conflict with the statement on page IV-22, par. 3 that burning of forest residues will be discouraged."

"You are now burning slash on soil types that the D.N.R. has classified hazardous for slash burning. You may need to be more specific in prohibiting this."

"A very specific fire management plan must be developed, giving clear management direction. Otherwise we will continue to fight Wilderness Fires inappropriately."

"Prescribed fires in Wilderness should not be allowed- Why waste the money?"

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0024, 0049, 0062, 0150, 0243, 0400, 0577, 0582, 0793, 0796, 0823, 2102, 2758, 2819, 2878, 2879, 2968, 3256, 3642, 3746, 3775, 3911, 4403, 4428, 4497, 4498, 4503, 9014, 0030S, 0038S, 0118S, 2061S

FOREST SERVICE RESPONSE:

The reader should review Chapter III, the Affected Environment, and Chapter IV, the Environmental Consequences, of the FEIS. In these sections an overview of the fire management strategies proposed for the Wenatchee National Forest can be found.

The Forest Service recognizes two types of fires: Wildfires and Prescribed Fires. They are managed differently.

Wildfires are managed to minimize suppression costs and resource losses, while prescribed fires are utilized to meet resource management objectives.

Wildfires are managed using a wide spectrum of suppression strategies in an attempt to minimize over all cost and resource loss. For example, some fires are limited in their spread by natural features like rock slides or creeks may only need surveillance, while fires that threaten life, property, or other high value resources will require immediate initial attack. However, the Fire Management objective remains the same-to minimize total cost and resource loss.

The Forest Service uses Prescribed Fire to meet resource management objectives. Prescribed Fires may be started by either a planned or unplanned ignition (e.g. lightning). In either case it is required that an appropriate burn plan has been developed and approved by the District Ranger or Forest Supervisor prior to implementing any prescribed fire activity. Prior to the management of any unplanned ignition in Wilderness a Fire Management Action Plan will be developed. This plan will contain a very specific outline of the conditions which must be met for an unplanned ignition to be considered a prescribed fire. If the fire does not meet all of these conditions it will be managed as a wildfire and appropriate suppression action implemented. All fires which threaten life, property, or important natural resources will be aggressively attacked.

SOCIAL AND ECONOMIC

199 MORE COSTS SHOULD BE INCLUDED IN THE FORPLAN MODEL; THE SOURCE OF SOME OF THE COST ESTIMATES ARE QUESTIONABLE.

COMMENTS INCLUDED:

“We are dismayed that of the 102 cost items, only 18 are tracked inside FORPLAN. Ten of those factors are listed as having a “significant variation” on the alternatives. We question the validity of the economic analysis ... given that the main costs such as arterial roads, collector roads, trails, and bridge and culvert construction are left out of the FORPLAN model. ... We recommend these major costs be included and all FORPLAN runs be rerun.”

“The averaging of different time series of data to derive values and costs which will be compared in future time periods in FORPLAN, is not an analytically sound procedure. ...costs derived from sold sales are probably higher than average operating costs.”

“The costs of the alternatives needs to be discussed and displayed. Virtually anything can be done, but the costs need to be shown. For example, it is technologically possible to remove all sediment from a stream downstream from a sloughed-out trail, but the costs incurred to do that would not be commensurate with the benefits.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0579, 4489, 4494, 4511, 0077S, 2042S, 2308S, 2445S

FOREST SERVICE RESPONSE:

The Forest managers developed the land allocations for each alternative. The FORPLAN model was used to estimate the timber harvest levels and management intensities. All of the unit costs affecting this decision, including local road construction costs, were used in FORPLAN. However, the model was not designed to include all National Forest budget costs for each resource area.

The timber management costs estimated from Wenatchee National Forest data are are discussed in Appendix B of the FEIS, “Costs Considered for Economic Efficiency Analysis”. All costs have been extensively reviewed for their accuracy. Some cost estimates for National forest lands may be higher than that experienced by industry, but we have no substantive grounds to change the cost estimates. The Plan also includes unit costs as items to be monitored.

All of the costs for each alternative are displayed in Chapter II of the FEIS. These costs reflect implementation of the resource standards and guidelines and the management prescriptions as described in Chapter IV of the Plan.

200 THE VARYING BUDGET FOR FISHERIES ENHANCEMENT IS NOT CONSISTENT BETWEEN ALTERNATIVES AND THE PLAN DOES NOT DESCRIBE HOW BUDGET CUTS WOULD BE DISTRIBUTED AMONG THE RESOURCE AREAS. CONCERNS WERE ALSO EXPRESSED ON THE USE OF KV FUNDING FOR FISH AND WILDLIFE PROJECTS.

COMMENTS INCLUDED:

“Budget increases are unlikely under Gramm-Rudman. Budget cuts are generally the rule. How would budget cuts be distributed among the resource areas?”

“Alternative E ... has the distinct negative features of lowest timber harvest, least mineral resource area activity, least payments to counties, lowest employment and lowest income. This makes it an especially poor place to coincidentally propose the highest level of appropriated funds for fisheries enhancement (which is the only reason for Alt. E’s highest ranking for anadromous fish production).”

“The figures for appropriated funds (in fisheries enhancement) do not appear to have any direct relationship to components of the nine alt. It appears that the peak amount of \$200,000 in Alt E could just as easily be included with the preferred alt (C).”

“Several alt would include the diversion of K-V funds to provide fishing access. This would further diminish the availability of these relatively modest funds for correcting past environmental damage on the Forest and fulfilling newly emerging needs in a timely manner.”

“... use KV monies you have collected from the timber sales on the study of old growth ecosystems and the wildlife. Can you account for all the KV Wildlife money that has been collected so far?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0299, 0579, 0580, 0896, 0901, 1300, 2032, 2999, 3162, 3256, 4169, 4455, 4485, 4490, 4492

FOREST SERVICE RESPONSE:

The Wenatchee National Forest annually prepares an outyear budget request. See Chapter II of the FEIS for the budget for the preferred alternative. It should be recognized that actual funding received in response to the submitted budget may not be the same as requested. Since Congress has the ultimate budget authority, the situation cannot be resolved through the Forest Planning process.

The Plan does describe resource management practices as well as levels of resource production from which the annual budget proposals are prepared. The standards and guidelines contained in the Plan specify the manner in which management activities will be carried out to achieve the goals and objectives in the Plan. In the event adequate funding is not available to achieve the identified outputs in a manner which meet the standards and guidelines, then outputs will be reduced to a level that does. Outputs and activities may be different than shown in the plan, however measures identified in the standards and guidelines must be met whenever the activities are undertaken.

The costs for fishery improvement projects have been reviewed and substantially changed for all alternatives. In general, fishery habitat improvement budgets were increased. More information on the fishery emphasis and budget by alternative is included in the FEIS, Chapter II.

This FEIS does not address specific KV funding projects, as that is a separate decision process. However, to address this concern the following is provided:

The Knutson-Vandenberg (KV) Act as amended by the National Forest Management Act of 1976 enables the collection of money for costs beyond the value of the timber in a timber sale. Among other things, money may be collected for activities relating to reforestation, and protecting and improving the future productivity of renewable resources including wildlife habitat management within the sale area. During a timber sale's preparation, its effects on other forest resources and enhancement opportunities are examined. These are compiled in a comprehensive sale area improvement plan for that timber sale. Money is withdrawn from the fund as the planned work is performed. Records documenting all of the KV funds collected and spent can be found at the Forest Supervisor's office in Wenatchee, Washington.

201 NON-MARKET VALUES SHOULD NOT BE ADDED TO MARKET DERIVED DOLLAR VALUES; THE VALUES OF CERTAIN RESOURCES, SUCH AS FISH, WILDLIFE, RECREATION, NATURAL SCENERY AND OTHER AMENITIES ARE UNDERESTIMATED. THE VALUE OF GRAZING IS OVERESTIMATED. TIMBER VALUES ARE PROBABLY LOWER THAN AVERAGE. IT IS INCONSISTENT TO TREND ONLY THE TIMBER PRICES AND NOT OTHER RESOURCE VALUES.

COMMENTS INCLUDED:

“When these market and non-market values are used in a forest planning model, one is conceptually comparing “apples and oranges”, which gives distorted and incorrect economic conclusions.”

“Only the commodity goods should have dollars assigned to them. For maximization of social net benefits, implicit dollar values should not be added to market-derived dollar values. ... alternatives can be assessed against the economic efficiency alternative to determine the value of market goods given up. ... Non-market values should be arrayed separately ...”

“... (timber) values derived from cut sales are probably lower than average.”

“The economic techniques for salmon resources are difficult to understand. ... priced values are limited to recreational uses on the forest and ex-vessel commercial fishery values. ... Modification will be necessary to reflect true national values.”

“... your economic efficiency calculations seriously underestimate the value of fish and wildlife. ... an arbitrary reduction of 37.5% was made from the ... 1985 RPA documents. We strongly believe the justification for that reduction ... is not correct. ... no attempt is made to incorporate fish and wildlife losses as costs in PNV calculations... losses should be measured from current conditions, not current direction.”

“... discounted costs and benefits for wildlife and fish ... remain deceptively constant throughout the alternatives. Please explain why ...”

“The economic value of recreation and forest amenities is under-estimated,”

“FORPLAN assumed natural scenery is of no economic value to North Central Washington.”

“Your grazing value of \$7.31/AUM is substantially higher than the fair market value for Region 6 of \$5.31/AUM given in the USFS/BLM grazing fee and evaluation report.”

“... bias is introduced through attributing a 1% real growth rate in timber prices, while holding other resource values constant over time.”

“Absence of a sensitivity analysis for real price appreciation of timber and not evaluating the consequences on the alternatives is inconsistent with regard to regional direction and NEPA.”

FOREST SERVICE RESPONSE:

The economic efficiency analysis considers the economic value related to recreation, wildlife and other amenities through the use of assigned dollar values that reflect the average user's willingness to pay. The Secretary of Agriculture Regulations require assigning value to nonmarket outputs to the extent possible. These values are based on the 1985 RPA figures and have been reviewed for their applicability to the Wenatchee National Forest, as described in Appendix B of the FEIS, “Economic Efficiency Analysis”.

These assigned values are used to determine the Present Net Value of the alternatives. There are, however, aspects of recreation and wildlife that cannot be expressed in quantitative terms. The non-quantitative aspects are considered in determining the overall Net Public Benefit of the alternatives. It is important to note that the preferred alternative maximizes the combination of PNV and net subjective values of non-priced outputs for all the alternatives considered.

The timber market is a cyclic market with periodic robust times and hard times. Timber values in the FORPLAN model reflect prices paid for timber sales which cover one full timber cycle. This period includes both the high and low markets for timber.

The economic techniques for fishery resources are described in Appendix B of the FEIS. Fish and wildlife costs and benefits have been changed to reflect greater differences between alternatives. These changes are described in the final EIS.

Not all aspects of recreation, natural scenery, or amenities can be expressed in dollar terms. However, these values are reflected in the land allocations and also as constraints in the FORPLAN model. In this respect, many of these amenity resource "constraints" have greater values than other resources.

The grazing value of \$7.31 is based on Economic Research Service market price estimations of the contribution of Wenatchee National Forest grazing to the net income of ranchers. There is National direction to use this source for grazing values.

The one percent real price trend for timber products is based on observed increases over the past 50 years. A sensitivity analysis for the real price appreciation of timber was conducted and is documented in Appendix B of the FEIS. In accordance with Washington (D.C.) Office Forest Service information and direction, the value of other resources, such as recreation use, can be assumed to not increase relative to other values (see discussion on demand curves in Appendix B of the FEIS).

202 MANY COMMENTS WERE MADE ABOUT THE ECONOMIC IMPACTS OF ALTERNATIVES AND THE POSSIBLE EFFECTS ON COMMUNITY STABILITY.

COMMENTS INCLUDED:

"The economic analysis needs to be expanded and updated. Employment numbers are from 1977 and are incomparable to the modern timber industry of 1986."

"All the enabling legislation from the Organic Act through the National Forest Management Act speaks to community stability. It is your responsibility to provide commodities which will ... provide for their families, their schools, and their communities."

"Through the efforts of the Yakima County Development Association and the Forestry Task Force of the greater Yakima Chamber of Commerce, an independent economic analysis of the impacts of preferred Alt. C has been conducted. The findings of this analysis indicate an actual job loss of 936 jobs and a loss of \$29.5 million in total income should Alt. C go into effect. This severe impact is totally unacceptable ..."

"The baseline timber harvest level being used to estimate job changes from variations in forest timber output should be based upon a recent 5 year average (about 136 MMBF) rather than the 10 year average (146 MMBF)."

“... the “Current Direction” Alt. ... is meaningless as a reference for determining job impacts of the proposed plan. ... We believe a fair and consistent comparison is the 171 MMBF/yr of sawtimber planned for sale in the existing timber management plan ...”

“The Forest should clearly describe the economic impacts of providing spotted old habitat ...”

“... impacts beyond the first decade should be considered.”

“The Forest is overstating the negative effects of Alt. E, F and G on general local economic activity, since the overall timber dependence in the EIS is relatively low when compared to Wash. State as a whole.”

“More emphasis, therefore, should be placed on such areas as recreation, and tourism.”

“The Forest is the sixth most heavily visited National Forest because of its primitive character, unsurpassed scenery, and clear clean waters to name just a few of the amenity values that are in the preferred alt. Implementation of the more destructive alt. will certainly cost local recreation based jobs and income.”

“We also believe that the alternatives would vary in their effects on recreation and that the local economy would reflect these differences. Fish and wildlife oriented recreation supports a significant amount of economic activity statewide ...”

“The economic effects of this reduction can be offset by harvesting of other commercial forests and by cutting the enormous amount of timber that has been already purchased but not cut by timber companies.”

“I don’t believe that the Plan’s economic impact figures are correct. It does not consider the fact that there is a huge surplus of logs from private lands that is currently shipped overseas.”

FOREST SERVICE RESPONSE:

Several major changes were made in the economic impact analysis since the DEIS. The most current data from 1982 were used in the economic model (IMPLAN). Local economic indicators, including timber-related employment and income, were derived from estimated changes in planned forest outputs. The reference point for timber harvest related comparisons is now the 5 year average Wenatchee National Forest actual harvest level from 1980 to 1985. Also, Douglas County is included in the model. The resulting figures are relative, not absolute, and are intended to provide a comparison among the alternatives and not absolute numbers for predicting employment and income.

Differences between the DEIS figures and the Yakima County Development Association study are due to several factors. The economic analysis by the Yakima County Development Association had a basic conceptual inconsistency, since the timber harvest data from the Washington State Department of Natural Resources (DNR) was from 1983-85, but model relationships were in 1977 terms. Also, it was discovered that the DNR data base had several incorrect figures. The updated IMPLAN analysis in the final EIS is based on the most accurate information currently available to estimate the relative economic impacts between alternatives.

Only the estimated economic effects for the first decade of Plan implementation are shown, since the economy is so dynamic and changes quickly. Provisions in the National Forest Management Act require Forest Plans to be revised every 10 to 15 years, so new economic conditions can be reflected in future plan revisions.

The various pieces of legislation cited by some respondents do direct the Forest Service to provide continuous flows of wood products for the use and necessities of the public. However, these same pieces of legislation charge the National Forest managers to make the most judicious use of all renewable resources which in combination best meet the needs of the American public. The impact on the local community is an important consideration, but the preferred alternative must maximize the benefit derived from all renewable resources, including outdoor recreation, range, timber, water, wildlife and fish. In establishing the timber harvest level, Forest managers considered, along with many other factors, the impact of National Forest timber supplies on local and regional economies.

Since the DEIS was printed, the amount of timber already purchased but not cut has been reduced significantly due to increased market demand. The FEIS has been updated to reflect these changes.

It is not within the scope of the Forest Plan to address the export of logs overseas. By law, most National Forest logs are not available for export.

See Appendix B in the FEIS, "Social and Economic Impact Analysis", for more information.

203 TIMBER SUPPLY AND DEMAND PROJECTIONS WERE NOT ADEQUATELY ADDRESSED IN THE ANALYSIS.

COMMENTS INCLUDED:

"The timber demand analysis in the Wenatchee Plan is abysmal. Though the Wenatchee area mills sell into competitive national markets where their individual output cannot affect price, the fixed mill locations and dominance of National Forest timber, gives the Forest Service virtual monopoly power over the mills. In assessing timber demand, the Wenatchee did not consider the sawtimber needs nor the increased pressures for timber from outside the traditional market area."

"The Forest has overstated the dependence of local mills on WNF timber ... The mills in the EIS are currently only about 40% dependent upon WNF logs. Therefore, a 25% reduction in existing WNF harvest levels (from about 136 MMBF) would result in about an 8% reduction in local timber supply. ... The Forest has attempted to make the case that the liquidation of major private timberland in the EIS will result in increased demands for WNF logs. However, the DEIS has presented no evidence to show the dependence of local mills ... for timber, furthermore, the Forest has presented little more than speculation that the timber outputs of these private owners will actually fall to zero in 10 to 20 years. Consequently, it is unclear that local mills will be looking for substitute logs for future operations."

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0035, 0243, 0519, 2003, 2053, 2087, 2842, 2913, 3551, 3652, 3684, 3862, 3989, 4246, 4426, 4450, 4477, 4484, 4489, 4496, 4501, 4507, 9037, 9060, 0011S, 2042S

FOREST SERVICE RESPONSE:

The timber supply and demand analysis was substantially expanded and updated to include more information from State of Washington analyses and from the Pacific Northwest Region. This discussion can be found in Chapter III of the FEIS.

The assumption about the relationship between Wenatchee National Forest timber demand and price is reflected in the horizontal demand curve used in the FORPLAN model. There is not presently enough information available to develop reasonable estimates of the demand functions for the timber resources offered by the Wenatchee National Forest. The use of a horizontal demand curve for timber is consistent with direction from the Washington D.C. Office of the Forest Service. See Appendix B of the FEIS, "Economic Efficiency Analysis", for more information on timber demand and price relationships.

204 NOT ENOUGH INFORMATION IS DISPLAYED TO SHOW WHICH AREAS ARE ECONOMICALLY EFFICIENT FOR TIMBER HARVEST AND THE PLAN WOULD CONTINUE TO EXPAND THE PRACTICE OF BELOW-COST TIMBER SALES. IN ADDITION, MORE INFORMATION IS NEEDED TO SHOW THE EXTENT TO WHICH AMENITY RESOURCES ARE BEING SUBSIDIZED.

COMMENTS INCLUDED:

“The Wenatchee planning staff .. has undertaken no economic screen to remove low-site lands where timber mgmt can only be practiced at an economical loss. As a result, the Plan would continue and expand the practice of below-cost timber sales, to the detriment of our forest resources. Many of the currently unroaded areas on the Wenatchee that are proposed for road construction and harvest are such low-site lands where road and sale costs will exceed timber receipts; ...”

“... no information is provided on the economic efficiency of timber harvest for those individual areas [analysis areas].”

“It is not now clear to what extent the Forest subsidizes amenities, or produces commodities where revenues exceed or are less than total production costs.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0262, 0562, 0577, 0659, 0789, 0841, 0896, 1952, 2743, 2772, 2776, 2790, 2846, 2919, 2922, 3227, 3261, 3270, 3327, 3553, 3710, 4210, 4224, 4417, 4433, 4455, 9114, 0011S, 0118S

FOREST SERVICE RESPONSE:

As a general rule, the Forest Service manages the Wenatchee Forest timber sale program so that the total benefits equal or exceed the costs over time. While economics is one of the important considerations in both choosing among alternatives and in individual timber sale design, it is not the only consideration. Timber sales are not necessarily designed solely for volume objectives. They may be designed to meet management objectives for other resources or the management of insect and disease problems. Thinning sales, needed to achieve growth of crop trees, frequently have costs exceeding revenues. However, the future value of crop trees is enhanced and both operations, considered together, are economically sound. While a “profit” may not be the deciding factor, an informed decision by Forest managers does necessitate consideration of perceived benefits and their cost.

This same principle is applied in choosing among alternatives. Here, the consideration of economics, other resources, and uses are contained in the concept of Net Public Benefit. Public benefit needs to be considered in terms of the issues, management concerns, and resource opportunities identified in the planning process. Use of the word Net denotes the underlying concept that a benefit with regard to one aspect of an issue may be detrimental from another aspect. Similarly, a response to one issue, for instance, timber supply, may adversely affect another issue such as wildlife habitat protection. Economic efficiency needs to be applied to an alternative as a whole.

The amenity resource values, referred to as “subsidies” by some respondents, are displayed as non-cash benefits to users in Chapter II of the FEIS.

205 THE CUMULATIVE ECONOMIC EFFECTS FROM ADJACENT NATIONAL FORESTS AND PRIVATE LAND ARE NOT ADEQUATELY ADDRESSED.

COMMENTS INCLUDED:

“Cumulative economic effects of declining timber harvest from adjacent National Forests and private land must be displayed in the EIS and should influence selection of the preferred alternative.”

“... wildlife and recreation values on private and State lands adjacent to WNF (e.g. L.T. Murray HMA) are directly dependent upon seasonal wildlife ranges within the WNF and should be taken into consideration.”

“the Forests ... are directed ... to evaluate, understand and be responsive to the cumulative impact of timber sale levels upon the economies of local dependent communities. The WNF has not made this evaluation ...”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

2849, 3992, 0032S, 0039S, 0040S, 0067S, 0069S, 0085S, 0087S, 0115S, 0706S, 1056S, 1243S, 1307S, 1371S, 1377S, 2042S, 2065S, 2249S, 2251S, 2308S, 2316S, 5075S

FOREST SERVICE RESPONSE:

The Pacific Northwest Region of the Forest Service conducted a more extensive analysis concerning the potential cumulative economic effects of Forest Plans in this Region. This information is discussed in the FEIS, Chapters II, III and IV. In addition, the Forest updated its analysis to include State of Washington projections for private timber supply.

The economic impact analysis was also expanded by including Douglas County in the study area and in the new IMPLAN model.

Wildlife and recreation values on private and State lands, to the extent they would maximize net public benefits, have been considered in the development of land allocations by alternatives.

206 THE SOCIAL EFFECTS ON PEOPLE'S ATTITUDES, BELIEFS AND VALUES NEEDS TO BE EXPLAINED.

COMMENTS INCLUDED:

“The basis of how, when, where, and to what extent attitudes, beliefs and values would be impacted needs to be explained. From the information presented in the table, there is no way to see how the inherent conclusions were derived. [DEIS, page II-134]”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

FOREST SERVICE RESPONSE:

The estimated social impacts of the alternatives are qualitative in nature and are based on professional judgement. Some of the information for the analysis comes from a socio-economic overview of the Wenatchee National Forest, which was updated in 1984 (available at the Supervisor's Office). The social impact analysis is described in Appendix B of the FEIS.

207 PEOPLE QUESTIONED THE VALUE OF THE OPPORTUNITY COST ANALYSIS FOR THE MANAGEMENT REQUIREMENTS IN THE SUPPLEMENT TO THE DEIS; SOME PEOPLE THOUGHT THE OPPORTUNITY COSTS WERE OVERESTIMATED, WHILE OTHERS THOUGHT THEY WERE UNDERESTIMATED.

COMMENTS INCLUDED:

"It isn't the diverse opportunities that cost. Cost are the result of management requirements for commodity uses that interfere with other opportunities: logging, mining, road building, grazing, ORV's. These should pay the entire cost of increased management requirements."

"I think the "opportunity costs" shown in Appendix I would indicate a fairly minor reduction from present plan and I would favor more severe reductions consistent with the objectives of other alternatives."

"MR's are rather confusing, especially the term opportunity cost. Why doesn't the FS say - this is how much timber we will be able to harvest under each MR. All your computer models seem to be based on timber revenues. How much money will be made off the increased recreational values that would be lost if these areas are clear cut. How much money would be saved in terms of road building? ... "

"The pileated / 3 toed / marten areas ... the opportunity cost is much lower than presented in the charts, as there will be considerable overlap with other management constraints."

"Re' opportunity costs - spotted owls. The bottom line is cash flow, near and long term. Do what you can for wildlife but meet the needs of our nation, near and long term."

"CHEC and other forest planning consulting groups have rightly criticized MR's and formulas used to adjust or determine opportunity costs. Wildlife and forest diversity suffers the most and so does primitive and semi-primitive ROS areas. Timber, roaded recreation and other utilitarian uses that yield high \$ figures win nearly every time. MR's for timber are based on local demands, and recent harvest levels."

"Costs for management requirements are already being experienced through increased sale preparation costs and reduced timber receipts due to contract protection requirements. The opportunity costs have never before been expressed. Since you are comparing to an existing base the true opportunity cost is understated."

"More representative opportunity costs might have been generated if the NC [No Change] Alternative was used as the baseline."

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0032S, 0039S, 0040S, 0067S, 0069S, 0082S, 0085S, 0087S, 0115S, 0158S, 0706S, 1056S, 1058S, 1062S, 1243S, 1305S, 1307S, 1308S, 1371S, 1377S, 2042S, 2065S, 2249S, 2251S, 2308S, 2316S, 2445S, 5075S

FOREST SERVICE RESPONSE:

The opportunity cost analysis is an accepted analytical technique to estimate the effects of the management requirements. The process is explained in more detail in Appendix I of the FEIS. Costs and values used in the analysis were extensively reviewed for their applicability to the Wenatchee National Forest. All opportunity costs are shown as changes from the Maximize PNV Benchmark, based on Regional Office direction.

208 THE JOBS AND INCOME EFFECTS OF THE NO CHANGE ALTERNATIVE ARE NOT REALISTIC; ALSO, THE TIMBER MARKET ASSUMPTIONS ARE QUESTIONABLE. THESE COMMENTS WERE IN REFERENCE TO THE SUPPLEMENT TO THE DEIS.

COMMENTS INCLUDED:

“We are highly skeptical that the NC Alternative would result in an increase in jobs and income at all when the timber industry is using ever fewer employees to process each board foot of timber as it improves mill efficiency. Tables IV-38 and IV-39 are very unclear ... Are the numbers displayed for direct jobs only, or do they include indirect jobs? If the job numbers in the table include indirect jobs, what economic multipliers did you use?”

“The social/economic comparison of the effects of the alternatives in Table S-1 is based on the assumption that the quantity of timber put up for sale controls economic outcomes. The amount of timber cut and lumber milled depend on what the market will take not the amount of stumpage offered.”

“It shows us what would happen if industry has its way. Short term profits not long term perpetual forests are their goals.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0020S, 1196S, 2318S

FOREST SERVICE RESPONSE:

The figures shown in the SEIS are changes from the 1977 employment levels. The entire economic impact analysis has been updated to the 1982 data base in the IMPLAN model and the new estimates are shown in Chapter II of the FEIS. These figures are meant to show relative changes, not absolute figures, and are intended to provide a comparison among the alternatives.

209 THE WENATCHEE NATIONAL FOREST SHOULD BE MANAGED FOR MULTIPLE USE.

COMMENTS INCLUDED:

“The Wenatchee National Forest should be managed in all of its areas for the best preservation of the land and the ecology, and also have sufficient areas for recreation to the general public, without further acquisition of land from private ownership.”

“We feel that there is already more Federal and State land designated for preservation and recreation than what is feasible to financially and efficiently manage.”

“The Wenatchee currently has over 841,000 acres of formally designated Wilderness areas (roughly 40% of the Forest). The remainder of the forest should be available for multiple-use management, including timber production.”

“Multiple use is a great concept until one group takes more than their share. If we set the forests aside for hikers, bikers, snowmobilers and other sportsmen and tourists the forests are still available later for harvest.”

“The National Forest should be maintained for all to use and enjoy, and if managed properly this can be achieved without a detrimental effect to those who depend on the forest for their livelihood or personal use.”

The Wenatchee National Forest must move into the 21st Century by recognizing “all” of the “other” values there besides wood fiber. The administrators of this Forest need courage and insight to see the right course, the protection of the whole resource, and to say no to those who would abuse it.

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDED:

0002, 0005, 0031, 0044, 0052, 0066, 0067, 0068, 0079, 0089, 0124, 0251, 0258, 0261, 0263, 0264, 0363, 0389, 0390, 0394, 0395, 0453, 0484, 0531, 0532, 0579, 0595, 0616, 0635, 0664, 0743, 0750, 0991, 0996, 1084, 1258, 1300, 1301, 1305, 1638, 1789, 1811, 1825, 1839, 1920, 1938, 1942, 1961, 1970, 1977, 1981, 1989, 2004, 2010, 2018, 2023, 2053, 2069, 2120, 2127, 2135, 2137, 2159, 2186, 2201, 2207, 2226, 2247, 2280, 2398, 2592, 2601, 2723, 2724, 2725, 2732, 2741, 2742, 2787, 2809, 2816, 2820, 2825, 2826, 2831, 2833, 2835, 2854, 2855, 2864, 2866, 2879, 2881, 2911, 2918, 2934, 2937, 2939, 2945, 2946, 2958, 2983, 2993, 2994, 2995, 3006, 3010, 3040, 3042, 3054, 3055, 3058, 3060, 3068, 3075, 3083, 3095, 3096, 3099, 3113, 3116, 3127, 3149, 3158, 3165, 3173, 3217, 3227, 3228, 3242, 3256, 3261, 3323, 3330, 3335, 3337, 3339, 3341, 3379, 3380, 3398, 3408, 3425, 3440, 3443, 3459, 3465, 3482, 3499, 3511, 3515, 3519, 3524, 3533, 3535, 3542, 3570, 3575, 3582, 3589, 3604, 3606, 3607, 3621, 3622, 3623, 3648, 3667, 3669, 3671, 3672, 3674, 3680, 3690, 3693, 3700, 3717, 3725, 3728, 3733, 3737, 3739, 3760, 3761, 3765, 3777, 3781, 3793, 3794, 3799, 3800, 3802, 3805, 3807, 3809, 3812, 3816, 3821, 3823, 3832, 3833, 3839, 3840, 3847, 3901, 3935, 3939, 3954, 3995, 4005, 4009, 4011, 4015, 4044, 4067, 4068, 4069, 4071, 4079, 4088, 4089, 4091, 4098, 4105, 4109, 4120, 4132, 4139, 4162, 4163, 4167, 4171, 4173, 4175, 4177, 4183, 4194, 4214, 4231, 4233, 4247, 4262, 4269, 4274, 4277, 4297, 4301, 4353, 4416, 4417, 4418, 4425, 4426, 4432, 4433, 4434, 4437, 4438, 4440, 4447, 4450, 4453, 4454, 4456, 4470, 4474, 4492, 4493, 4494, 4500, 4504, 4508, 4511, 9004, 9007, 9014, 9017, 9021, 9027, 9032, 9033, 9041, 9046, 9047, 9065, 9066, 9067, 9082, 9092, 0019S, 0034S, 0038S, 0074S, 0106S, 0176S, 0317S, 0662S, 0672S, 0695S, 0696S, 0720S, 1100S, 1105S, 1136S, 1176S, 1200S, 1215S, 1216S, 1239S, 1305S, 1359S, 1370S, 1380S, 1420S, 2045S, 2046S, 2061S, 2199S, 2272S, 2365S, 2445S, 3428S, 5043S, 5071S, 5094S, 5096S

FOREST SERVICE RESPONSE:

Forest managers must carefully weigh and consider all impacts of major Federal actions prior to and during implementation of a Forest Plan. The Forest's task is to balance the different uses of the Forest, including timber, wildlife, fisheries, recreation, range, watershed and Wilderness. The range of alternatives addresses public concerns about multiple use management, as well as many other concerns. The preferred alternative maximizes the net public benefits.

PLANNING

210 SOME INFORMATION IS NOT CONSISTENT WITH OTHER PLANS, INCLUDING THE BUREAU OF LAND MANAGEMENT SPOKANE DISTRICT PLAN.

COMMENTS INCLUDED:

“Forest Service land Allocations in Numbers 1 and 2 Canyon appear inconsistent with adjacent BLM lands managed primarily for watershed. BLM lands in Entiat Valley and north of Lake Chelan are primarily managed for range and wildlife....”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

9094

FOREST SERVICE RESPONSE:

While some alternatives may have allocations which appear inconsistent with the BLM, Spokane District Resource Management Plan, most alternatives are consistent. The preferred alternative has EW-1, Key deer and Elk Habitat, allocations on lands adjacent to BLM and State of Washington wildlife lands (refer to alternative C & I allocation map). All Forest Service alternatives have EW-2, Riparian-Aquatic habitat protection zone, allocations along all streams, lakes and wetlands. Due to the narrow width of the allocation it does not show on maps. Also for watershed protection the Forest-wide Standards and Guidelines apply to all Forest Service lands, (refer to Chapter IV of the Forest Plan and Appendix D of the FEIS).

211 QUESTION THE LEGALITY OF INCORPORATING THE ALPINE LAKES MANAGEMENT PLAN INTO THE FOREST PLAN.

COMMENTS INCLUDED:

“We reserve all objections about the legality of incorporating part of the Alpine Lakes Management Plan into this Forest Plan....”

“We agree with the Forest position that the Alpine Lakes Management Plan ought not to be amended at this time. A date should be set for a review of the entire Alpine Lakes Plan at some point in the future.”

“The Forest Plan proposes that the land allocations and management as presented in the Alpine Lakes Management Plan be held constant. Both the imposition of management

requirements and new timber yield expectations as part of this proposed plan do change those land allocations and management. We feel this opens the opportunity for further review and consequently we have included allocation revisions for Alpine Lakes in the map.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0416, 0594, 2132, 2719, 2751, 2795, 3233, 3483, 3487, 3746, 3879, 4110, 4186, 4484, 4534

FOREST SERVICE RESPONSE:

The incorporation of the Alpine Lakes Management Plan into all alternatives was a decision made by both Forests (Wenatchee and Mt. Baker-Snoqualmie) to allow the eight year old plan stand the test of time, and is in accordance with 36 CFR 219.2 (b). The Plan and FEIS state that some modification was done to update the Plan to meet management requirements contained in NEPA. This is also in accordance with direction in the Alpine Lakes Management Plan (page 153 under Plan Revision), “The Alpine Lakes Area Management Plan will maintain its identity in the forest-wide plans now being developed by the Wenatchee and Mt. Baker-Snoqualmie National Forests. Minor revisions of the Alpine Lakes Plan may occur in the forest plans.”

Another revision made in the Alpine Lakes Plan is the preliminary administrative recommendations on Wild and Scenic Rivers. This is also covered in the Alpine Lakes Management Plan (page 14), “This FEIS makes no evaluation of these rivers for their qualifications as Wild and Scenic Rivers but each alternative preserves, for the future, the option to so designate.”

Because it is incorporated by reference, review and amendment of the Alpine Lakes Management Plan will be accomplished in the same way the remainder of the Forest Plan will be amended and revised. This is described in Chapter V, Section D, of the Forest Plan.

212 THE DEIS DOES NOT PRESENT A FULL RANGE OF ALTERNATIVES.

COMMENTS INCLUDED:

“The Wenatchee National Forest needs to consider a full range of management alternatives including the following: 1. Substantially reduce livestock grazing allotment and no grazing alternatives. 2. Substantially reduce ORV allocation and no ORV use alternatives. 3. Alternatives that prohibit timber harvest in all naturally evolved Old Growth forests. 4. Alternatives which do not include construction of the proposed Naches Pass road.”

“Likewise, no alternative provides for less than 1000 miles of new road to be constructed, also a violation of 36 CFR 219.12 (F)(1).”

“No alternative withdraws any part of the Forest from leasable mineral development outside of existing wilderness. This violates NFMA regulations (36 CFR 219.12 (f)).”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0044, 0065, 0067, 0224, 0528, 0579, 0579, 0582, 1947, 2053, 2053, 2132, 2779, 2832, 2930, 3068, 3190, 3256, 3551, 3553, 3593, 3771, 3878, 3911, 4186, 4484, 4486, 4510, 9094

FOREST SERVICE RESPONSE:

The FEIS contains modified alternatives which address the major concerns expressed by a majority of the public. These are in addition to alternatives displayed in the DEIS, which are designed to provide a reasonable range of opportunities for resource use and management across the Forest.

The number of alternatives which could be developed are unlimited, but a reasonable range of alternatives was developed based on the original scoping of alternatives, public responses to the DEIS, and existing federal laws. Existing federal laws require the Forest Service to make forage, timber and recreational opportunities such as ORV use available to the public.

Changes made in the FEIS include grazing allocations, ORV allocations, and harvesting of Old Growth. Alternative F in both the DEIS and FEIS allocate all roadless areas to an unroaded management. The road construction included in alternative F is necessary to harvest timber and conduct other management activities in existing roaded portions of the Forest.

213 THE DEIS DOES NOT INCLUDE A WORST CASE ANALYSIS WHEN THERE IS INCOMPLETE AND UNAVAILABLE INFORMATION.

COMMENTS INCLUDED:

“A footnote to Table II-3a states that no population data are available for several management indicator species..... NEPA requires that it be obtained and included in the EIS; if not obtainable at reasonable cost, its lack must be acknowledged. (40 CFR 1502.22a).”

“The Wenatchee National Forest admits a clear lack of information on a variety of resource issues that would be affected, yet no worst case analyses are presented.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

3239, 3256, 3493, 3553, 3866, 9094

FOREST SERVICE RESPONSE:

NEPA regulations (40 CFR 150.22, July 1,1986) have been changed to direct agencies, which are “evaluating reasonably foreseeable significant adverse effects on the human environment in an EIS and there is incomplete or unavailable information” to make clear that such information is lacking.

In many cases lack of information, including information on existing animal populations, does not necessarily mean that an evaluation of reasonably foreseeable significant adverse effects on the human environment can not be made, or that the information is essential to a reasoned choice among Alternatives in the FEIS. Very often the specialist was making the disclosure that information needed to display an accurate number was not available, and that highly accurate numbers for wildlife species and/or similar information could not be obtained. In other cases the information may have improved the evaluation. Disclosures of this nature has been done throughout the FEIS, Appendices and Forest Plan.

The Forest has determined that there are no reasonable, foreseeable, significant impacts to the resources referenced in the documents with the application of mitigation measures in the management prescriptions and Forest-wide Standards and Guidelines (refer to Chapter IV of the FEIS). The monitoring plan in Chapter V of the Forest Plan will be implemented to help detect and control adverse impacts. This plan will serve as a means for collecting relevant information about presently unknown adverse effects.

214 THERE ARE PROBLEMS WITH THE PROPOSED MONITORING PLAN AND REVISIONS ARE NECESSARY.

COMMENTS INCLUDED:

“We request that you prepare a monitoring plan, with budget, which reflects monitoring, and evaluation on an ongoing basis.”

“Connected to any such standards should be monitoring elements designed specifically to address the adequacy or effectiveness of the values chosen.”

“Your monitoring program should also rely on public comment. Example - if I find an inconsistency in the field with the adopted Forest Plan, there should be a procedure for my comments....”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0582, 1952, 2135, 2201, 2879, 3138, 3235, 3255, 3256, 3343, 3550, 3553, 3725, 3731, 3746, 3871, 3877, 3992, 4298, 4446, 4485, 4495, 9094

FOREST SERVICE RESPONSE:

The implementation and monitoring section (Chapter V) of the Forest Plan has been rewritten and expanded. Monitoring worksheets which go into much more detail than contained in the Monitoring Plan Table in Chapter V, are displayed in Appendix F of the Forest Plan. Chapter V discusses public involvement during the Environmental Analysis stage of implementation of the Plan. The public will have the opportunity to get involved for comment on projects and activities permitted through the Forest Plan during the Environmental Analysis process to assure compliance with the National Environmental Policy Act, and other Forest Service Regulations including the Forest Service Appeal process.

215 EXISTING UNIT PLANS AND OTHER RESOURCE GUIDELINES WERE IGNORED IN THE NO CHANGE ALTERNATIVE.

COMMENTS INCLUDED:

“The supplement also states that, “no adjustments have been made to reflect new information for resources other than timber. These include such things as soil, cultural, riparian, and wildlife resources; (pg II-6). It is not clear to us why the Forest’s planning team chose to ignore the unit plans in their development of the No Change alternative. By ignoring the existence and role of its unit plans, the Wenatchee has still not prepared a true No Action Alternative as required by NEPA.”

“The text gives the impression that what has been conducted since the inception of NFMA is totally out of compliance with the act. The adoption of unit plans prior to NFMA, completion and incorporation of The TRI system, EA completion for each timber sale, increased deposits for wildlife and fisheries work, and revisions to the timber sale contract all provide emphasis on other resources. You have been incorporating the concepts and spirit of NFMA for years and doing an excellent job of it! In other words management requirements (MR’s) have been in place under other names and without their being acknowledged. For this reason “No Change” can be a viable alternative and should be given the full financial and modeling examination of any other alternative.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0002S, 0005S, 0024S, 0037S, 0088S, 0119S, 0215S, 0423S, 0696S, 1158S, 1187S, 1243S, 1370S, 1379S, 1574S, 1577S, 1578S, 1579S, 2042S, 2178S, 2195S, 2244S, 2278S, 2308S, 3648S

FOREST SERVICE RESPONSE:

Existing Unit plans were incorporated into the No Change alternative to the extent that the Timber Management Plan amendments reflected the direction and corresponding timber yields adjustments reflected by the Unit Plan direction. An example would be that the roadless areas in the Chelan Unit plan are reflected in the NC alternative as amended by the Washington State Wilderness Act because adjustments were made in the Timber Management Plan to reflect this direction.

It is also correct that we have been incorporating the concepts and spirit of NFMA for years into our projects and activities occurring on the Wenatchee Forest Lands. However, the problem that exists with the No Action is that no adjustments or amendments have been made to the Timber Management Plans to reflect the reduction in timber yields required to fully incorporate the concepts into a viable forest-wide comprehensive plan. An example of this is the Alpine Lakes Management Plan deferred adjustments to the timber base until the pending revision of the timber management plans.

The in context wording of the supplement (pg II-6) is; "Adjustments in the TM plans were made only to the acres available for harvest and the subsequent Potential Yield. No adjustments have been made to reflect soil, cultural riparian, and wildlife resources. The management requirements (MR's) are also not applicable in this alternative." This is a statement of fact concerning the amendments to the TM Plans and does not mean that some of the direction in unit plans were not included in the No Action alternative. However, when the Timber management plans are not amended to reflect the direction in Unit plans which require adjustments in potential timber yield, it would be inconsistent to ignore the consequences to other resources and also maintain the No Action potential yield. In fact, when all of the concepts and direction from Unit Plans and various laws (T&E Species Act, NFMA and others) are incorporated into the No Action alternative, the result is Alternative A/NFMA with the corresponding annual sale quantity of 121.4 million board feet, instead of the 176.8 million board feet potential yield in the No Change Alternative.

MANAGEMENT REQUIREMENTS

216 ALTERNATIVE HABITAT SIZES AND DISPERSAL DISTANCES FOR WILDLIFE MANAGEMENT REQUIREMENTS WERE NOT CONSIDERED.

COMMENTS INCLUDED:

"The Forest Service has not analyzed all reasonable ways to achieve Management Requirements."

"The discussion in the Management Requirements Analysis Appendix is merely an after-the-fact justification of the Forest's choice of a particular method. This doesn't comply with the requirements of NFMA or NEPA."

“The 2000 acre size of SOHA’s and the assigned large distances between SOHA’s are woefully inadequate to preserve the distribution and viability of these species.”

“Providing a minimum number of sites and acreages in areas where timber harvest will occur will result in fragmentation of Marten and Three-Toed Woodpecker populations.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0030S, 1062S, 1370S, 1578S, 2064S, 2308S, 2316S

FOREST SERVICE RESPONSE:

Although the Forest has not analyzed all alternatives, it has analyzed a reasonable range of alternatives based on scientific information available for each wildlife species. As a result of the MR analysis, comments to the Supplement and new information and direction, including the Spotted Owl FSEIS to the Regional Guide, changes have been made to the preferred alternative for Spotted Owls, Marten, Three-Toed Woodpecker and Pileated Woodpeckers. These changes affect sizes of habitats, and/or dispersal distances and/or habitat characteristics for these species. In addition, Spotted Owl habitat areas will be managed in a “dedicated” strategy.

217 TREATMENT OF SPOTTED OWLS IN MANAGEMENT REQUIREMENTS ANALYSIS

COMMENTS INCLUDED:

“Spotted Owls have survived well without Management Requirements.”

“The overwhelming majority of public is against massive set-asides for Spotted Owls.”

“Your proposed Spotted Owl management areas are much too large. Five or ten acres should be plenty for any kind of bird. Spotted Owls have been documented on virtually every timber type known in the Pacific Northwest.”

“The Washington Wilderness Coalition supports the strongest, most stringent protection for wildlife and habitat in Management Requirements.”

“We fully support dedication of habitat areas.”

“Fragmentation is one of the main threats posed by proposed timber cutting on the Northern Spotted Owl.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0002S, 0068S, 0342S, 1062S, 1067S, 1305S, 2053S, 2199S, 2308S, 2316S, 2319S

FOREST SERVICE RESPONSE:

The Spotted Owl Final Supplement to the Environmental Impact Statement (FSEIS) for amendment to the Pacific Northwest Regional Guide was published after the Forest’s Supplement, including the Management Requirements analysis, was released to the public in October, 1988. The Spotted Owl FSEIS disclosed the consequences of a number of alternatives and selects a course of action for the Forest to follow in managing Spotted Owls. The selected alternative is intended to provide for a viable Spotted Owl population. It provides specific direction for managing Spotted Owls on the Wenatchee National Forest.

218 MANAGEMENT REQUIREMENTS WERE NOT SUBJECT TO PUBLIC REVIEW.

COMMENTS INCLUDED:

“The Forest Service should immediately withdraw their implementation of Management Requirements until they are subject to public review.”

“The Forest and its users would be better served by a public review of Management Requirements.”

“The assumptions the Forest made toward the wildlife requirements and the dispersal distance between habitats has had no public involvement nor has the Forest engaged in any legal rule making process.”

“We question the right of the Forest Service to establish the rule making process without due process of public involvement.”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

2137, 3487, 4483, 4484, 4489, 0005S, 2318S

FOREST SERVICE RESPONSE:

As explained in the introduction to the Supplement, one of the purposes of the Supplement was to gain further public involvement.

Management Requirements are listed in 36 C.F.R. 219.27. The ways or means to implement these Management Requirements are analyzed in the Supplement. The Supplement provides opportunities for the public to comment on all aspects of the ways or means to implement Management Requirements. Comments from the public are considered in the development of the Final EIS. Prior to the development of the DEIS, considerable effort was spent by the Forest and others in developing and reviewing the biological habitat requirements for wildlife. Consultations were made with agencies or others who had scientific knowledge regarding wildlife management. In addition to that information contained in the Management Requirement appendix, the Draft EIS included discussions of Management Requirements in Chapter II and Appendix B.

The specific ways or means of meeting Management Requirements can be viewed as the Forest’s specific expression to meet the congressional mandate in Section 6 of the NFMA. The Management Requirements and the ways to meet them constitute the agency’s scientific determination of the minimum resource protection standards necessary to comply with the law.

219 THE RANGE OF SCIENTIFIC OPINION AND UNCERTAINTY REGARDING MANAGEMENT REQUIREMENTS HAS NOT BEEN DISCLOSED.

COMMENTS INCLUDED:

“The Forest must discuss the extent the means to meet legal requirements are based on scientific research, field experience or professional judgement.”

“Where contrary scientific research exists, it must be noted and its implications discussed.”

“The Wenatchee’s Supplement failed to fully discuss the scientific uncertainty involved in its Management Requirement analysis.”

“Even if there are some areas of imprecision in the Management Requirements, it would appear that management above minimum levels is more cost effective in the long run.”

“The assumption of 100% occupancy rates in Management Indicator Species is extremely unrealistic and underestimates the required habitat.”

FOREST SERVICE RESPONSE:

Appendix I was amended to include the following kinds of statements. “There are a range of scientific opinions as to what the habitat requirements - in contrast to desirable habitat - are. These differences of opinion are disclosed.

Often, the pool of scientific knowledge is insufficient to provide the entire basis for defining the specific conditions or standards that will satisfy or meet a management requirement. When this happens it is necessary to rely on the field experience and the professional judgement of knowledgeable professionals and to establish monitoring and research that will provide better information for future planning efforts.

CUMULATIVE EFFECTS

220 SEVERAL INDIVIDUALS AND GROUPS EXPRESSED CONCERN ABOUT THE TREATMENT OF CUMULATIVE EFFECTS IN THE DRAFT DOCUMENT. SOME WERE UNCLEAR AS TO WHAT THE OFFICIAL DEFINITION WAS FOR CUMULATIVE EFFECTS. OTHERS COMMENTED THAT THE CUMULATIVE EFFECTS ISSUE DID NOT ADDRESS ALL RESOURCES, AND WAS FOCUSED TOO NARROWLY. SEVERAL REVIEWERS EXPRESSED CONCERN ABOUT THE MANAGEMENT OF INTERMINGLED LANDS.

COMMENTS INCLUDED:

“Page IV-30, recreation setting. Have cumulative effects of more roads and recreation been included in big game output models?”

“Land patterns - The past 15-20 years has seen the pattern of forested stands on the Cle Elum RD greatly change. Two-thirds or more of most watersheds have been converted to plantations. This is and will continue to cause problems with meeting visual, watershed and wildlife needs. For instance, water yields to the Yakima drainage are probably near the peak level for the next rotation period. Or take the elk population, with an abundance of forage now, in a few years as plantations close, cover will be over abundant and forage limited, with the area dominated by sub-merchantable stands.”

“Mixed ownership management - this issue has not been adequately addressed in any of the planning documents, despite attempts by ranger district personnel to draw attention to it. The plan’s projected yields of timber for all alternatives are unrealistically high in checkerboard areas due to considerations the FS gives to what is happening on private land. Impacts on watersheds, wildlife habitat (including spotted owls) and creation of large man-made openings, all serve to limit and preclude NF options for management. This is not recognized. All cumulative effects should be identified, addressed, and yield outputs adjusted accordingly. This is not currently being done and projected outputs are too high, given the cumulative effects expected and associated restrictions.”

“The issue of cumulative effects was also simplified. It is assumed that basins with more timber harvesting scheduled and having a larger proportion of area in private ownership have a greater risk of cumulative effects. Further discussion of what cumulative effects are and how they occur would provide a better insight about their significance when comparing alternatives.”

“It is here in Kittitas County and largely within the boundaries of the Cle Elum R.D. of the WNF that the enormous acceleration of Burlington Northern’s logging activity has its greatest impact. The cumulative effects resulting from BN’s logging are severe in all alt., they would be very severe considering the prescriptions proposed in your preferred alt. C How can the WNF competently address wildlife and watershed issues within the parameters of the multiple use concept and the 1976 NFMA in a situation where every other section will be a clearcut--As will be the situation in about ten years. The Alpine Lakes Plan was placed intact as a part of all alts. It was developed well before the cutting level of Burlington Northern made its impact. Dare I ask if it might be appropriate to consider changes in the ALAMP for the purpose of reducing the Level of impacts to wildlife, watershed, scenic, and other values?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

FOREST SERVICE RESPONSE:

NEPA regulations require an assessment of cumulative effects of management activities on all resources (40 CFR 1500-1508). The basic definition of “cumulative effects” is “the impact on the environment which results from the incremental impact of the actions when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time” (40 CFR 1508.0). The application of this concept can range from a local to a global basis; however, for the purposes of this analysis, the effects have been discussed on a Forest-wide level. It is also important to recognize that “cumulative effects” can be positive, neutral, or negative. Most of the time, people tend to focus on just the negative effects.

During the scoping process for the Wenatchee Forest planning effort, the principal areas of concern in regard to cumulative effects were the potential impacts of timber harvest and associated road construction on watershed condition (soil, water quality, quantity) and on fish and wildlife (habitat diversity and numbers). Other areas of concern were cumulative impacts on scenery and recreational resources.

During the preparation of the final documents, the assessment of direct, indirect and cumulative effects for all resources has been revised. More detailed discussions of the potential cumulative effects of management activities on the various resources have been include in Chapter IV of the FEIS.

For example, the environmental consequences section on wildlife now addresses potential cumulative effects on wildlife habitat in areas of the Forest with intermingled ownership. In another example, in between the Draft and Final, an analysis was conducted on several drainages in which concern existed for the potential for cumulative effects on soil and water resources from management on private and National forest lands. This study included twenty-six sub-drainages on the Cle Elum Ranger District and four sub-drainages on the Naches Ranger District. As a result of this analysis, timber harvest on National Forest lands in two sub-drainages was deferred until a more acceptable hydrologic condition exists.

As noted above, intermingled lands are common to some parts of the Forest. Management of these lands was identified as a major issue during the scoping process. Concern exists for the potential for cumulative effects from management activities on the various ownerships on numerous resources. The management of National Forest System Lands in these areas is complex and opportunities include reduction in impacts through deferral, unilateral activity scheduling, coordinated activity scheduling and land exchange. The Forest Service is only one of the many entities involved in watershed management in these areas. The Forest will fulfill its role in this system through more site specific analysis of the cumulative effects issue during project level planning. However, the responsibility for coordinated management in these watersheds is shared by all entities.

221 SEVERAL REVIEWERS CHALLENGED THE ADEQUACY OF THE 40% CUTOVER LEVEL AS A TRIGGER TO MANDATE A CUMULATIVE EFFECTS ANALYSIS.

COMMENTS INCLUDED:

“We also question whether 40% of a watershed in created openings with trees less than 15 feet tall will adequately avoid cumulative effects of increased sediment loading. There is no discussion of the basis for this strategy, or whether this is too much or too little for a particular sub-basin.”

“In addition, as stated above, there is no discussion of why 40% created openings, or 1,000 acres is used as a guideline to reduce impacts.”

“One of the Forest’s tools for mitigation is to restrict forested openings (openings less than 15 feet tall) to less than 40% in any watershed greater than 1,000 acres Has this 40% limit been shown to be adequate? Is it based on research or otherwise documented? Has an analysis been done to show that the Forest can meet their annual cut and still maintain 60% of a watershed with trees greater than 15 feet tall?”

LETTERS WITH COMMENTS ON THIS SUBJECT INCLUDE:

0579, 0808, 1952, 3223, 3239, 3350, 3621, 4485, 4495

FOREST SERVICE RESPONSE:

The Forest Service guideline was developed after a major flood event in Cabin and Log Creeks on the Cle Elum Ranger District in 1975. At that point in time, it had been estimated that nearly fifty percent of both drainages were in a harvested condition (trees less than four feet tall). The District Ranger felt that the 1975 flood event was directly related to the amount of cut over land, because other unharvested drainages in that same locality has not experienced the flood damage. About this same time, Dr. Glen Klock (USFS Forest Sciences Lab, Wenatchee, Washington) developed the KWCEA model, which provided a systematic means of evaluating risk associated with lands in a harvested condition. Klock made the assumption that watershed recovery had occurred when at least one-third of the trees (fully stocked stand of conifers) was fifteen feet or taller.

The Forest Soil Scientist and Forest Hydrologist recommended to the management team that fifty percent was probably too much of any particular sub-drainage to be in a harvested condition. They further recommended that the Forest Service use thirty percent as a point where an on-site investigation would be needed to determine watershed condition. The management team agreed that fifty percent was probably too much, but they also thought that thirty percent was too conservative; therefore, it was agreed that when sub-drainages that were one thousand acres or larger in size were in a harvested condition, or if there was a major concern about cumulative effects identified in the I.D. process, that a thorough analysis would be made to determine the degree of risk for that particular sub-drainage. The Forest Service has used this guideline as a caution flag, so that watershed condition would be evaluated by a team of specialists before any particular drainage has more than forty percent of its area in a harvested condition.

The one thousand acre size limit was adopted as a result of a concern in the Thompson Creek sub-drainage (approximately 1300 acres) on the Leavenworth Ranger District. This guideline seems to be applicable to other parts on the Forest as well.

In 1988, the Forest re-evaluated the guideline, basically refining it, but not really changing the basic concepts. A Forest-wide Standard and Guideline in the soil section of the Plan, Chapter IV, has been developed to incorporate this concept. As written, this standard mandates that a watershed analysis be conducted whenever "more than 40% of the forested area in a 1,000 acre or larger sub-drainage is projected to be in openings at any one time." More importantly, this new standard requires that a detailed watershed analysis be made by an appropriate group of specialists whenever project scoping identifies cumulative effects to be an issue or concern (considering all ownerships).

Using this standard, the Forest Supervisor had a team of specialists make an analysis of some forty different sub-drainages on the Cle Elum and Naches Ranger Districts during the summer of 1988. Thirty of these sub-drainages required a detailed analysis (26 on the Cle Elum District and 4 on the Naches District). Rescheduling of several timber sales occurred as a result of this analysis. From the data that was developed, both Districts will be able to monitor these sub-drainages and determine how well the model values reflect watershed risk in the event of a major flood.

As more information becomes available, modifications of this standard may be necessary because of timber type, soil differences, or some other selected factor; however, for this point in time, this is the best method the Forest Service has for assessing watershed condition on a Forest-wide basis. It must be recognized that analysis of this kind is only one element used in the decision making process. The District Ranger must still decide whether or not the risks are too great to harvest timber and build roads in any particular sub-drainage. The standard does not set a limit as to how much land will or will not be harvested in any sub-drainage. The standard does establish a point at which a more thorough analysis must be conducted as part of the assessment of the potential effects of a project or number of projects on a watershed system.

COMMENTS ON PLANNING DOCUMENTS BY

ELECTED OFFICIALS

FEDERAL AND STATE AGENCIES

INDIAN TRIBAL GOVERNMENTS

This section contains photocopies of letters received from elected officials, Federal and State agencies, and Indian Tribal Governments on the Draft Environmental Impact Statement, Proposed Forest Plan, and Supplement to the Draft Environmental Impact Statement.

Due to the number and length of responses received from these groups, we have elected to photocopy those portions of the letters containing direct comments on the planning documents. Original letters with all enclosures and addenda are on file and may be viewed at the Forest Supervisor's Office in Wenatchee, Washington.

Mr. Donald Smith
Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, Washington 98801

Dear Mr. Smith.

As you are aware, October 1 brings the deadline for public comment on the proposed land and resource management plans for the Wenatchee National Forest.

Over the next several months, your staff will be sorting through the hundreds of responses to glean an overall perception of public opinion on how the Wenatchee National Forest should be managed in the years to come. The quality of the forest's relationship with the people who use it will be closely related to the responsiveness that you show in reviewing those questionnaires.

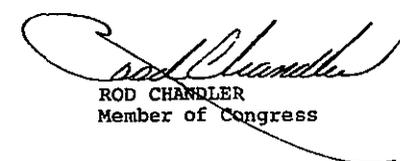

Certainly, if your mail is anything like mine, you have heard many complaints about conflicts between hikers and off-road-vehicle users. As I mentioned in my August 6 letter, I have received well over 400 letters from people who consider it a definite conflict for hikers and ORV's to be using the same paths. At that time, I provided you with a summary of the complaints that my staff put together. However, I feel that you should be fully aware of the seriousness the people of this state place on this issue. Enclosed you will find photocopies of the most helpful of the letters I have received to date. I hope that you will give them your full consideration and include them in the factors that you use in planning multiple use areas for the Wenatchee Forest.

Wenatchee is becoming known as a National Forest with serious conflicts between ORVs and hikers. In particular, Myrtle Lake Trail Nos. 1400 and 1404, which are said to be the heaviest areas of conflict in the state. Other trails with very high incidences of conflict are the Chelan Summit Trail to Boiling Lake Nos. 1261 and 1259, East Nason Ridge No. 1583, Devils Gulch No. 1220, Yellow Hill No. 1222, Duncan Hill No. 1434, Mission Ridge No. 1210, Mount Lillian No. 1372, and Tronsen Ridge No. 1204 of the proposed Chelan/Gold Creek Hiking Area.

In the proposed North Fork Entiat Hiking Area, North Fork Entiat River Trail No. 1437, South Pyramid Creek to Pyramid Peak No. 1439, and Pyramid Peak Trails Nos. 1433 and 1411 are reported to be areas of moderate to high conflict. In the proposed Mad River Hiking Area, the Upper Mad River Trail to Blue Creek Camp Trail No. 1409, Mad Lake Trail No. 1409, Two Little Lakes Trail No. 1426, Whistling Pig Loop Trail Nos. 1424 and 1417, Klone Peak Loop Trail Nos. 1426 and 1409, Cougar Mountain Trail Nos. 1419 and 1418, and Shepto Creek Trail No. 1429 have all been reported to be areas of moderate to heavy conflict. And finally, in the proposed Teanaway-Negro Creek Hiking Area, trails with moderate to high conflict include Negro Creek No. 1210, which is temporarily closed to ORVs but will reopen next year, Three Brothers No. 1211, Iron Mountain Trail No. 1212, Miller Peak Trail No. 1379, Iron-Bear-Teanaway Ridge Nos. 1351 and 1364 and Blewett Ridge County Line Trail No. 1226.

I would hope that you will take these concerns very seriously as you review the Forest plan for Wenatchee National Forest and make sure that wherever there is conflict, ORV use be eliminated so the letter and spirit of Executive Orders 11644 and 11989 can be fully enforced.

Sincerely,

ROD CHANDLER
Member of Congress

STATE OF WASHINGTON
OLYMPIA

September 28, 1986

Don Smith, Forest Supervisor
Wenatchee National Forest
301 Yakima Street
Wenatchee, Washington 98801

Dear Mr Smith

Prior to the public hearing in Yakima in late July I had studied the background information and various plans suggested by the Forest Service for the management of the Wenatchee National Forest. Thank you for sending me those materials. Then at the meeting I heard more about alternative "C", the preferred plan, which would reduce available harvestable timber by 22%, and have a significant impact on our area in loss of jobs and loss of income. It astonished me to hear that the Forest Service thought we could absorb and accept this severe loss

As one of the elected representatives of this area I have been working diligently with other state and local officials to increase the opportunities for people to find work in the Yakima Valley. We are struggling mightly to turn around our high unemployment figures by actively looking for new markets for all our products, agricultural, forestry, and small manufactured items. The state has established CINTRAFOR specifically to enhance the marketability of the wood products industry, and our legislature has consistently sought ways to help business and industry. There have been a few signs lately that the timber industry is slowly coming back. For that we are thankful.

Of course preservation of wildlife and encouragement of recreation are important to all of us, but a million and a half acres, more than half of the 2.2 million acre Wenatchee Forest, have already been allocated for wilderness, scenic, and roadless recreation.

We must look at a more balanced management plan not one which would provide for one use at the expense of the other. I believe the Essential Alternative Plan which equates to your Plan "B" with some minor modifications would be better suited to the needs of our area.

Please take time to carefully re-evaluate the proposed management plans. I would also like to suggest you give serious consideration to reviewing the data used in formulating your choices. I believe there is more recent data which could give a more accurate picture of the industry as it is today, and consequently a more accurate picture of the magnitude of the impact. This is an extremely critical issue for all of central Washington, and indeed, the economy of our state.

If you and your staff members feel it would be helpful to meet with elected officials from our area I am sure we would be very interested in discussing this issue with you. Please let me know if I can be of help in sponsoring such a gathering.

Sincerely,

Shirley Doty

Re: Wenatchee National Forest
Draft Environmental Impact Statement
Proposed Land and Resources Management Plan

Dear Mr. Smith,

Let me take this opportunity to thank you for allowing me to make some comments on this proposed plan. I have tried to gather as much information on this issue as I can while developing my particular position.

I am fully aware of the need to preserve our national forests for the recreational and enjoyment purposes, that we all cherish so much in our beautiful valley, while at the same time allowing reasonable timber harvest to provide the jobs and the economy in the area. I believe you have attempted to do that in plan C/2200 and I am reasonably comfortable with that position. I do however feel the yield could be raised closer to the ten year average of 166 million board feet, which would be some improvement on the C/2200 position.

In the area of the inventoried roadless areas I would support the timber industry on that issue. I suggest that the forest service move rapidly to develop that acreage removed from the roadless designation to assist in the possible increased timber harvest.

I certainly do appreciate the thorough study and assessment by your department. I know you will get a great number of responses which is certainly the way it should be. I trust your judgement will be a sound one in the struggle to keep the economy moving and still protecting the environment.

Thank you in advance for your consideration of this request.

Sincerely,

George

Dear Mr. Smith

I attended a meeting in Ellensburg at the Hal Holmes Center on September 10 regarding forest management. It was the consensus at that meeting that Plan B be adopted with minor changes. I certainly agree with that opinion. It appears that to accept anything else would definitely affect construction funding of our schools and, most of all, affect the economy of those counties involved.

I would hope that you could waive any decisions until all economic conditions have been thoroughly studied.

Sincerely,

Curt Smith

Ref. 1-3-86-I-302

Mr. Donald H. Smith
Forest Supervisor
Wenatchee National Forest
301 Yakima Street
PO Box 811
Wenatchee, Washington

Dear Mr. Smith:

This is in response to your request for comments on the proposed Land and Resource Management Plan and the Draft Environmental Impact Statement for the Plan for the Wenatchee National Forest, Chelan, Kittitas and Yakima Counties, Washington. Our comments in this letter pertain only to the Plan's coverage of endangered species. Additional Fish and Wildlife Service comments were provided to you in a September 25, 1986 letter.

On September 22, 1986 we provided you with a list of threatened, endangered and candidate species that may occur on the Forest. The gray wolf (*Canis lupus*) was not included on that list, but you should be aware that it is possible that portions of the forest might be used by this species.

Additional candidate species that were omitted from the Plan and which should be included for management consideration are the bull trout (*Salvelinus confluentus*) and the California bighorn (*Ovis canadensis californianus*).

Baseline data on listed and sensitive (candidate) species are needed for long range management. Regardless of which alternative is selected by the Forest Service for overall management of the Wenatchee National Forest, good baseline data are essential for determining population trends of endangered species, identifying their use areas, and implementing the various tasks directed in recovery plans for listed species conservation. We recommend that criteria be developed for inventorying listed and sensitive species populations on the Forest. These criteria should be included in the Standards and Guidelines section of the Plan along with provisions for incorporating information obtained from the inventories into the various planned Forest activities. In considering the input of Forest activities to listed species, please remember that any action that is authorized, funded, permitted or carried out by the Forest that may affect a listed species requires consultation pursuant to Section 7(a)(2) of the Endangered Species Act of 1973, as amended.

The Plan indicates that one bald eagle nest is located on the Forest. We recommend that the Standards and Guidelines section plan for the development of a site specific management plan for this and future nest territories.

As you are aware, the Service is considering listing of the plant species *Hackelia venusta*. Should this species be submitted for proposed listing, it is likely that this will occur prior to the final release of the Forest Plan. This point should be made in the Plan and Environmental Impact Statement.

As directed in our September 22, 1986 species list to you, and pursuant to Section 7(c) of the Act, you should prepare an assessment of the impacts to listed species from implementation of the Forest Plan. Should you determine that any aspect of proposed management may affect listed species, you should request formal consultation with this office.

If we can be of further assistance to you, or if you have questions regarding your responsibilities under the Endangered Species Act, please contact Jim Michaels at the above phone number and/or address.

Sincerely,

Charles A. Dunn

REPLY TO
 ATTN OF M/S 443

Don Smith
 Forest Supervisor
 Wenatchee National Forest
 P.O. Box 811
 Wenatchee, Washington 98801

Dear Mr. Smith:

In accordance with our responsibilities under Section 309 of the Clean Air Act and the National Environmental Policy Act we have reviewed the Draft Environmental Impact Statement and Proposed Land and Resource Management Plan (DEIS and Plan) for the Wenatchee National Forest (WNF). The WNF is located in Central Washington and includes 2.1 million acres.

Certain components of the documents we thought were particularly well done. We especially appreciated the candid approach to describing additional data needs and the effective approach to discussing cumulative effects.

Based on our review we have rated the DEIS EC-2 (Environmental Concerns - Insufficient Information). Enclosed is an explanation of our EIS rating system. The primary reasons that we have environmental concerns are as follows.

- o The process for managing forest activities is not sufficiently detailed that we can be assured adverse environmental effects, particularly to water quality and fisheries, will be prevented. We suggest more fully describing the management processes of the WNF.
- o Standards and guidelines for Fisheries and for Water, Soil, and Air, need to be more fully discussed/developed in the Final EIS/Plan. A process for collection of adequate baseline data in conjunction with project planning should be specifically proposed, so that the next plan will have an appropriate information base.

The details of our comments are included in the enclosed review report. Several of the items identified in this review were discussed in the meeting we had with your staff in Seattle on September 24, 1986 and in subsequent telephone conversations. This interaction has been useful for us in becoming familiar with issues on the WNF.

The intent of our comments is to be constructive. We are confident that by addressing our concerns and comments, the WNF can present a Final EIS and Plan which clearly shows that important resources will be adequately protected, while providing WNF personnel with the necessary flexibility to manage day to day activities on the ground.

Thank you for the opportunity to review this DEIS and Plan and for sending us the Best Management Practices document and Water Quality Monitoring Plan. We plan to submit comments on the latter two documents under separate cover. If you have any questions about our review, please contact Wayne Elson of our EIS and Energy Review Section at (206) 442-1463.

Sincerely,

Robert S. Burd
 Director, Water Division

U.S. ENVIRONMENTAL PROTECTION AGENCY REVIEW REPORT ON THE DRAFT
ENVIRONMENTAL IMPACT STATEMENT AND PROPOSED LAND AND RESOURCE
MANAGEMENT PLAN FOR THE WENATCHEE NATIONAL FOREST, WASHINGTON

PROCESS DESCRIPTION

The Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (Plan) rely heavily on subsequent environmental analyses and data collection for pinpointing specific impacts from forest activities. In order that we can be satisfied that the environmental effects of the selected alternative are acceptable, we need to have a complete picture of the forest management process. There are a number of elements within the forest management process that we believe are very important to minimizing adverse environmental impacts, particularly water quality effects. They include

- 1 A data base of existing conditions from which technical experts and the public can judge expected effects and level of uncertainty of the predictions
- 2 Best Management Practices (BMPs) and prescription development
- 3 Selection of BMPs for a particular activity [Environmental Assessment (EA) preparation] and how uncertainty is factored into selection
- 4 Thorough on-site inspection and administration, verifying that a particular activity is occurring as prescribed in contracts, leases or permits
- 5 Monitoring after the completion of an activity to determine whether impacts were accurately predicted
- 6 Repairing damage caused by adverse effects that exceeded predictions
- 7 Upgrading BMPs or prescriptions to correct inaccurate predictions

The DEIS and Plan did an excellent job of describing the available data base. The fact that the WNF realizes there are significant data gaps is very important in how the plan is structured. On-site inspection, repairing damage and upgrading BMPs have weaker commitments and are not clearly described. The most important component that is missing is a good description of how these elements are related and dependent on each other. For example, the Standards and Guidelines make heavy use of the goal statement as the basis for determining compliance with a particular standard. This is not specific enough, it weakens the link between predicting impacts (pursuant to the goal) and determining actual impacts. The process for on-site inspection, repairing damage, and upgrading of BMPs where necessary should be more specifically outlined.

As discussed on page V-3 of the Plan, Ranger Districts will have much of the "doing" responsibility. This responsibility should be described in context with the process described above. This will aid in understanding the Plan's system of accountability.

On page V-20 of the Plan, the monitoring program for water states that "further action will be required" when BMPs are not meeting water quality standards. This component of the Forest Management Process is very important. The Standards and Guidelines do not specify at what point this "further action" will be needed and how "further action" will be taken. Not only should the Standards and Guidelines be more specific, but the process description needs more detail here.

We would recommend that the Final EIS and Plan include a complete process description addressing the elements listed above.

WATER QUALITY

The presentation of water quality data on page III-75 is good. It does raise a number of questions, however, as it is difficult to determine water quality standards compliance from averaged water quality data. It should be noted that, typically, water quality standards are written for instantaneous and site-specific compliance. For example, Table III-32 indicates that a maximum value of 900 Nephelometric Turbidity Units (NTU) has been measured on the WNF. Similarly, pH values have been recorded well below, and fecal coliform counts well above, state standards. Where have these violations occurred? To what extent may they reflect managed activities on the WNF? (Would some of the Entiat Experimental Forest data help answer this?) We suggest revising the discussion to emphasize where (and under what conditions) water quality problems have been noted, as opposed to giving forest-wide averages. Statements regarding compliance with standards should acknowledge these problems.

For the Yakima basin, where land ownership is intermingled, the DEIS identifies a situation "where a significant cumulative effect on sediment yield may exist in the future." We note that, under fisheries, such a situation would trigger the Forest Service to consider altering its planned activities in the basin. We believe such consideration is appropriate, and should also be afforded in situations where a cumulative effect on water quality is likely. The Final EIS and Plan should provide standards and guidelines for how such situations will be handled.

The relationship of water quality monitoring to the other elements of the forest management process is not clearly spelled out in the DEIS and Plan. It is recognized that a separate and detailed monitoring plan document has been prepared. However, the Final Plan should include more definitive goals and objectives for the use of monitoring data gathered. Monitoring is a key element in the management framework to evaluate actions, modify activities, and upgrade BMPs where necessary to achieve desired environmental protection results. The Final EIS and Plan should be expanded to provide better policy and program direction for an effective monitoring plan.

The adequacy of the monitoring plan to assess environmental impacts and methods to ensure that the assessments are used in management decisions are key factors in EPA's ability to evaluate the adequacy of Forest Plans and EISs. The Final Plan should clearly outline how monitoring will be carried out such that mid-course corrections can be made in forest management. This serves as a *system of accountability, reduces adverse effects from any uncertainties in predicting Plan impacts, and makes it clear to the public how the plan will be implemented*. As the uncertainty in being able to predict water quality and fish habitat effects increases, it becomes more important to insure that activities are monitored to prevent adverse effects.

DOMESTIC AND IRRIGATION WATER SUPPLIES

According to the DEIS the WNF provides 95 percent of the water used for irrigation and domestic water systems in Chelan, Kittitas, and Yakima Counties. To ensure that current and any future surface drinking water supplies are protected information including location, size, and source of drinking water supplies should be included in the Final EIS. Also any instances of waterborne disease occurrences should be summarized, as should any water quality monitoring information (e.g., for turbidity and fecal coliform levels).

Watersheds or areas within watersheds which are particularly sensitive to activities which might have a detrimental effect on water supplies should be identified. Sensitive areas may be defined by such factors as the physical features of the watershed, the number of water users in the watershed, the type of water treatment employed, the location of water intakes, and past history of water quality problems. There may also be effects on ground-water supplies. The potential impact of the proposed Plan on drinking water aquifers should be addressed.

SOILS

The DEIS documents the level of existing soil data and the need for additional data as well. The Plan needs to outline the process for collection of adequate soil survey data where it is not currently available, prior to the occurrence of soil disturbing activities. Standards and guidelines should specify that such activities will not occur without consideration of adequate data in project planning analyses. Forest-wide standard No. 11 under Water, Soil, and Air (Plan page IV-98) should be revised by removing statements such as "where available."

FISHERIES

Chapter III of the DEIS provides a very good overview of existing (at the time of printing) knowledge of the status of fish habitat and fish population on the WNF. Many of the numbers used in the DEIS should be changed to reflect more recent information (for example, we are aware that more spring chinook have returned to the Yakima basin in the last 2 years than the 10 year average of 500 noted in the DEIS). Obviously, given recent increases in escapement, changes in harvest management related to the US-Canada Treaty, and the goals

of the Northwest Power Planning Council (NWPPC) and their efforts under the Columbia River Basin Fish and Wildlife Program, maintenance of high quality spawning and rearing habitat on the WNF will become increasingly important. Habitat quality is one key component to the success of all these efforts.

We are pleased that the DEIS considered not only presently utilized habitat on the WNF, but also included potential escapement and smolt habitat capabilities under the assumption that efforts to decrease losses "downstream" will be successful. The DEIS acknowledges (page III-47) that high quality habitat directly affects the harvestable portion of the runs. We concur, given equal escapement levels (regardless of the percentage of losses downstream) degraded habitat will ultimately provide fewer adult fish. The same harvest level cannot then be supported if escapement is to be able to sustain the run. Of course, avoiding impacts to habitat for stocks that are not currently self-sustaining (minimum viable) is even more important to the success of the efforts to rebuild them.

We were also pleased with the candid approach taken in the DEIS to identifying where data on fish habitat quality and fish populations is lacking. Very little specific information exists for most of the WNF. It is obvious that this plan will not be able to make project-specific decisions in many cases. The immediate focus for the upcoming implementation and planning period must therefore be on significantly upgrading the fisheries data bases. This should be done in conjunction with project planning and implementation, so that the next plan will have an adequate foundation.

It is for this reason that many of our comments focus on the following points:

- 1 The adequacy of the process to gather site-specific data, where little exists initially, in conjunction with planning for individual activities over the course of the planning period.
- 2 The adequacy of the process to gather data over broader areas (i.e., relating to potential cumulative effects of many individual activities), where little exists initially over the course of the planning period.
- 3 The adequacy of standards and guidelines for protecting fish and fish habitat, and the extent to which they take into account site-specific and cumulative effects data as it is collected.

We consider these areas to be key to managing fish habitat on the WNF so that impacts are minimized. Each of these areas is discussed separately below.

Site-Specific Data We consider it crucial that adequate data be available prior to initiating any ground-disturbing activity. Where little site-specific information on fish and fish habitat exists, additional data should be collected. We are not suggesting that all surveys for the entire forest need to be completed before any projects can take place. Rather, we believe an assessment of habitat quality and potential fish use in the general area of a proposed activity should be completed, and the results incorporated in project planning. This allows identification of areas that are either highly important or already degraded such that (in either case) more stringent

protection than is afforded by the Plan's forest-wide standards and guidelines can be provided. Areas that could not be protected could be avoided entirely. Without such an assessment prior to projects occurring, significant impacts could result. Such impacts would have to be considered reasonably avoidable and, therefore, unacceptable.

In relation to this issue, the DEIS and Plan is not consistent. In some instances, collection of additional data is proposed. In other cases, there is a tendency to conclude that impacts are not significant - and thus do not require special management consideration - without any data to support such a conclusion. For example, it is assumed that the habitat in the Entiat watershed has returned to nearly the pre-fire/flood condition, but it is noted that there "is very little data to support this contention." The result is that "monitoring will be done only through the regular forest-wide monitoring plan to detect change." We believe that in identified or potential problem areas, more intensive monitoring is necessary to 1) determine whether recovery from past impacts is occurring, and 2) to support whether and how further projects can occur without exceeding management thresholds or adding to already significant impacts. One of the purposes of the regular monitoring program is to identify such potential problem areas requiring more intensive monitoring.

Similarly, after describing existing instances of potential cumulative impacts within the Wenatchee drainage, the DEIS (page III-52) states that, "as a matter of judgement, it is not thought that any of the activities have resulted in significant impacts to the fisheries on the Wenatchee watershed, as a whole" (emphasis added). Where impacts are believed to exist, actions should be taken to mitigate them, and further activities should not significantly worsen them directly or cumulatively. More specifically, protection of beneficial uses is necessary wherever the use (fish populations) occurs, it can not be traded off against lack of impacts elsewhere to conclude overall nonsignificance.

Another example appears in the forest-wide standards and guidelines for soils (No. 11, page IV-98 of the Plan). This item states that detailed soil survey information will be utilized "where available" (emphasis added). The DEIS notes repeatedly that where detailed surveys are not complete, information is inadequate for project planning. Since mass movement and excess erosion can have significant impacts (direct and cumulative) on fish habitat, we consider site-specific soils information to be vital prior to soil disturbing activities occurring. Without it, adequate mitigative measures can not be identified. Once again, all surveys do not need to be complete before any activities occur. Rather, local site-specific assessments must accompany project planning where data is inadequate. Standards and guidelines should include this requirement.

Overall, the DEIS does a good job of acknowledging the serious lack of existing data on the WNF. The Final EIS/Plan should be more careful not to misinterpret existing data, and should rely more on collecting sufficient site-specific data over the course of the next implementation and planning periods. In particular, a standard should appear in the Plan requiring that adequate fish habitat information be available prior to implementation of activities which may affect the quality of that habitat. Then, the Monitoring

K-286

Plan should be expanded to describe not only the regular forest-wide program, but also the project-specific data collection process and the framework for more intensive monitoring where impacts have occurred or are predicted.

Cumulative Effects Data The regular monitoring program should also be designed to gather data pertinent to potential cumulative effects both in basins where such impacts are considered at least possible, and where "none known" appears in the matrices. Since most basins fall into these categories, it is the regular monitoring program that should include parameters of concern for cumulative effects (as identified in the fisheries, soil, and water matrices).

The draft Plan does generally identify fish habitat inventories as a priority, and element 7.1 of the Monitoring Plan describes monitoring for fish habitat capability in the four major watersheds on the WNF. However, we find no discussion of when and how the needed habitat inventories will be carried out. Also, the level of monitoring described does not directly reflect the impacts identified in the DEIS (in particular, each of the WNF's 27 major subbasins, at a minimum, should receive the monitoring discussed).

Standards and Guidelines for Fish Habitat Protection The Forest-wide Standards and Guidelines that relate to activities potentially affecting fish and fish habitat are appropriate as far as they go. We believe they should be expanded and made more specific in order to ensure the protection intended. In some cases there need only be minor wording changes for them to be more effective (such as changing "should" to "will" in guideline No. 6, page IV-89, regarding mitigation for adverse effects to habitat). In most cases, however, standards need to be attached to the general guidelines listed. For example, how will fisheries needs be met in the design, construction, and maintenance of roads (No. 8, page IV-90)? (The specific guidelines for roads do address fisheries to some extent, and the WNF's BMPs are cited. It would be helpful, however, to outline key BMPs directly in this portion of the Plan.)

Similarly, how will the results of fish habitat inventories be used in project planning? Specific standards should be presented to provide the framework within which activities can be considered acceptable. These standards should relate to all pertinent components of fish habitat. As one example, a standard for an acceptable level of instream sedimentation would allow a project planner or team to determine whether predicted increases in erosion from an activity would be acceptable, given pre-project levels of sediment.

Such standards would insure that project plans minimize adverse effects and help to determine where more stringent management prescriptions are necessary. The plan proposes one scheme of management for all fish streams. We anticipate that completion of more surveys will allow identification of both relatively more important habitat areas and areas that have been or may be degraded by management activities. For both types of areas, protection beyond that provided in prescription EW-2 would be warranted.

We were pleased to note that the forest-wide standards for Range include cutoffs for allowable livestock forage use as a function of slope and soil hazard class and management intensity level (Plan, page IV-93). While we agree that impacts of grazing will vary by slope and soil hazards, the rationale for the percentages chosen should be provided.

Similar support should be provided for the 40 percent cutoff for created openings in drainages larger than 1000 acres (Plan, page IV-97), and for the minimum percent effective ground cover per erosion hazard class (Plan, page IV-98) These types of standards are appropriate and we were pleased to see them proposed The EIS should document why they are the appropriate values

Connected to any such standards should be monitoring elements designed specifically to address the adequacy or effectiveness of the values chosen This is particularly important on the WNF where detailed data on existing fish habitat quality are at present generally lacking, and adequate soil surveys are not yet complete

The standards and guidelines included in Management Prescription EW-2 ("Riparian-Aquatic Habitat Protection Zone") make up the primary direction for protection of fish habitat on the WNF We concur with the decision that the streamside zone warrants its own management prescription We further concur with the intent embodied in the stated purpose of management within the zone "The primary purpose is to maintain optimum riparian habitat for wildlife and fish and to protect wetlands " We have already noted that, given the lack of currently available data, it will be essential to collect site specific data to implement management strategies for streamside zones The EW-2 prescription should be conservative enough and specific enough so that significant impacts will be avoided It is from this perspective that the following comments on the EW-2 prescription are provided

Given the stated primary purpose of the prescription, it is important that the EIS/Plan evaluate why management activities would improve on the functions and values of the zone over a "no entry" scheme In other words, since only one management scheme is proposed for the entire streamside zone, the EIS should thoroughly evaluate whether the proposed scheme is reasonable The best way to do this is for the EIS to consider, to the extent possible, alternative schemes ranging from "no entry" to "no special management consideration "

Some of the important details of the EW-2 direction appear in Chapter IV of the DEIS (pages IV-40 and 41), but are not reflected in the EW-2 prescription itself in the Plan In particular, the specifics of rotation period under the extended shelterwood scheme, and the stipulation that no more than 10 percent of a given subbasin's zone be affected in a decade, are not reflected in the Plan Assuming they will be added back in, further guidance on the amount of shelter trees to be left within the zone should also be provided How many trees per acre would need to be left to assure adequate woody debris recruitment, and how is blow-down and natural mortality factored into this number?

Throughout the prescription, it is stated that various management activities could only occur to the extent that they are "compatible with the goal " Lacking are standards delineating when activities would be considered compatible We realize that specific determinations must be made on a project-specific basis, however, guidance for making those determinations is appropriate in the Plan (Please refer to the above example regarding a standard for acceptable instream sedimentation)

K-287

More specific standards are also needed under the following elements of the EW-2 prescription

- Wildlife Surveys and Plans, No 1 In addition, this element should cite the more project-related survey work that we have indicated is needed A brief statement committing that such work will be performed would suffice
- Range Planning and Inventory, Activity Statement No 1 Standards should be provided to guide how allotment management plans can ensure maintenance or enhancement of the zone
- Timber A general expansion of this element is needed The direction provided in the DEIS (page IV-40 and 41) should be included Beyond this, further detail for when timber management activities would be compatible with the goal for the zone would be helpful (e g , when would firewood collection generally be compatible with optimizing fish habitat quality?)
- Water, soil, and air This element emphasizes improvement and rehabilitation projects Additional specific guidance relative to protecting beneficial uses of water (via management of the streamside zone) would be appropriate For example, practices to reduce delivery of eroded sediment to streams help protect both water quality and fish habitat Limiting of livestock grazing in watersheds having domestic water supplies similarly can reduce the significance of impacts
- Facilities, Road Operation (Maintenance) Procedures to minimize impacts are mentioned, but are not outlined Operators should not only be advised of the appropriate procedures, but should be required to follow them Thus, outlining them as standards in the Plan is essential

IMPLEMENTATION DIRECTION

The Plan states on page V-2 that "If environmental analysis shows little or no environmental effects are expected beyond those identified and documented in the Forest Plan Final EIS, the analysis will probably result in a categorical exclusion " This needs to be rephrased The type of environmental document should be based on the significance of an activity not whether or not it is mentioned in the Final Plan

Monitoring element 7.1 addresses Management Indicator Species (MIS) For anadromous fish, chinook salmon are proposed as the MIS Sockeye salmon have clearly different habitat requirements, as do coho and steelhead Chinook habitat alone does not adequately reflect the needs of these other species These anadromous species should also be considered MIS for the WNF, so that the monitoring plan will address potential impacts to all of them

The physical and biological parameters that will be measured for fish should be outlined Sediment, large organic debris, canopy, flow regime, and nutrient cycling are all examples that come to mind of important components of a stream's capability to support fish

The trigger for further evaluation here is a 10 percent change in long-term habitat capability. Depending on the existing condition of a particular habitat area, this may or may not be appropriate. Until more site-specific data are available for the next Plan, we cannot determine whether up to a 10 percent change is acceptable in all areas. A more appropriate trigger for the time being would be to reverse the proposal, as follows: "Decrease in habitat capability below 90 percent of natural capability." This would dovetail well with a project-specific data collection program. The existing habitat capability would be estimated first, and predicted impacts evaluated against whether resulting capability would be within 90 percent of the stream's natural potential. Where existing conditions are already below this standard, further activities should only be allowed in conjunction with direct habitat improvement work or other mitigation.

The water monitoring element (10) is the key component of the monitoring plan. The adequacy of many of the other resource management activities will be determined by their level of impacts on water quality and quantity. This element of the monitoring plan should contain the general policies and procedures upon which the more detailed WNF water quality monitoring plan is based.

The emphasis of the water quality monitoring should be focused in sensitive or high hazard areas, rather than randomly monitoring 10 percent of the management activities. Monitoring should also focus on the protection of beneficial water uses as identified in the water quality standards for Washington. It is important to include the process the WNF will use to verify whether the designated management activities are adequately protecting water quality and beneficial uses.

ALTERNATIVES

The way that Chapter IV is structured appears to cause some environmental effects to be missed. Environmental consequences are discussed in terms of each alternative on each environmental component like recreation, scenery, wilderness, and fisheries. For example, there appears to be no discussion of the effect of 113 family campgrounds and 27 resort and organizational sites on the environment. The current and future water quality effects of sanitary facilities and solid waste disposal should be included in the Final EIS.

AIR QUALITY

Approximately 13,542 cubic feet of firewood are projected to be taken from the WNF. The health effects of wood smoke appear to not have been considered.

Smoke particles emitted from incomplete combustion of wood are small enough to penetrate deep into the lower respiratory tract when inhaled, these particles may have relatively high concentrations of compounds that are known and suspected carcinogens. The FEIS and Plan should identify the health impacts of wood smoke.

Forest land managers that provide firewood have a unique opportunity to educate the public regarding fuelwood use and air pollution through the permit process. For example, pamphlets discussing the association between wood stoves, air pollution, and health concerns, or providing tips on efficient wood stove operation, could be distributed with fuelwood permits. If appropriate literature is not readily available, we would be happy to provide examples that are being used elsewhere.

CUMULATIVE EFFECTS

We commend and recognize the conscientious attempts to address cumulative effects, both in Forest Service-managed watersheds, watersheds of intermingled ownership, and off-forest. The matrix approach to discussing these potential impacts is understandable.

As a general comment, the extent to which the matrices can be relied upon (regarding accuracy - i.e., should some "none known" entries be "possible?") is in direct relationship to the reliability of the data going into them. In most cases, very little data exists. The numerous "none known" entries appear to more precisely represent "not known" situations. "None known" implies data have been collected and no cumulative effects were identified. It would appear that in most cases little or no data have been collected in order to identify cumulative impacts.

We would recommend the most appropriate use for the matrices at this point is to help direct the forest-wide monitoring program. Where cumulative effects are known to be possible or likely, more intensive monitoring should be implemented in conjunction with project planning. Where no data on cumulative effects exists, the ambient monitoring plan should include stations and parameters to gauge the overall "health" of the watershed. (For example, temperature and sediment data in larger order streams may be collected first. If indications of basin level impacts are noted, more intensive monitoring should accompany project planning and implementation.) Used in this way, the matrices will "fill themselves in" for the next planning period. Also, more stringent standards and guidelines should apply to activities planned in basins where significant cumulative impacts have already occurred.

Another general comment is that the Plan needs to address how identified cumulative effects will be taken into account in the future. In the fisheries section of the DEIS (Chapter III), it is stated that "In subbasins where a cumulative effect could result in a significant change in fisheries habitat potential, Forest Service activities may need to be altered and/or mitigated." We concur with this statement. However, it appears to address only basins with intermingled ownership. It should apply to any drainage. Also, a similar statement does not seem to exist for other resources, such as soil and water, which can suffer significant cumulative effects as well. Finally, the positive intentions of the statement do not show up in the Plan under either the forest-wide standards and guidelines, or those for individual management prescriptions. These sections of the Plan should include not only the general commitment and direction of this statement, but also more specific standards and guidelines for carrying it out. (For example, thresholds of impact beyond which cumulative impacts are considered significant.)

K-283

The Environmental Consequences chapter does a good job of addressing cumulative effects for the various alternatives. In particular, the separate discussions for groups of watersheds having different levels of intermingled ownership lands helps to disclose the differences among the alternatives. We concur that as more private ownership and acreage are allocated to timber harvest, the potential for cumulative effects increases. It is important for the Final EIS and Plan to note, however, that cumulative effects can also become significant in basins wholly managed by the WNF, and that monitoring will be designed to identify such impacts before they become unacceptable. The Final EIS and Plan should also provide specific support for the cutoff values used. For example, the potential for cumulative effects is assumed to be insignificant where less than 30 percent of a basin is available for harvest. Similarly, a 40 percent value is used as a forest-wide standard for basins exceeding 1000 acres. What are the bases for these figures? Whatever the figures used, the monitoring plan should be designed to address the question of whether they are appropriate.

SUMMARY OF THE EPA RATING SYSTEM
FOR DRAFT ENVIRONMENTAL IMPACT STATEMENTS
DEFINITIONS AND FOLLOW-UP ACTION *

Environmental Impact of the Action

LO--Lack of Objections

The EPA review has not identified any potential environmental impacts requiring substantive changes to the proposal. The review may have disclosed opportunities with no more than minor changes to the proposal.

EC--Environmental Concerns

The EPA review has identified environmental impacts that should be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

EO--Environmental Objections

The EPA review has identified significant environmental impacts that must be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no-action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

EU--Environmentally Unsatisfactory

The EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality. EPA intends to work with the lead agency to reduce these impacts. If the potential unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the CEQ.

Adequacy of the Impact Statement

Category 1--Adequate

EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis or data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.

Category 2--Insufficient Information

The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the action. The identified additional information, data, analyses, or discussion should be included in the final EIS.

Category 3--Inadequate

EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action, or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analyzed in the draft EIS which should be analyzed in order to reduce the potentially significant environmental impacts. EPA believes that the identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. EPA does not believe that the draft EIS is adequate for the purposes of the NEPA and/or Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS. On the basis of the potential significant impacts involved, this proposal could be a candidate for referral to the CEQ.

COMMENTS ON THE DRAFT EIS

We have reviewed the Draft Environmental Impact Statement (EIS) on the Wenatchee National Forest Proposed Land and Resource Management Plan, and we offer the following comments for your consideration.

1. We would like to compliment you on the good job you have done of addressing both existing and proposed energy transmission corridors.
2. In our review, we noted that the Wenatchee National Forest has designated Research Natural Areas as corridor exclusion areas. It is our understanding that the only types of areas that can be called exclusion areas are those having a statutory prohibition to rights-of-way for lineal facilities or corridor designation (see enclosed July 13, 1982, memorandum from R. M. Housley, Deputy Chief, US Forest Service, to Regional Foresters, R-1 through R-6). In the Northwest, the only National Forest areas we are aware of that are known as exclusion areas are those designated as Wilderness Areas, Primitive Areas, or National Recreation Areas (where specifically excluded by legislation). Therefore, to be consistent with Forest Service policy, we believe Research Natural Areas should be identified in the EIS as avoidance areas rather than exclusion areas. Bonneville Power Administration would make every effort to avoid Research Natural Areas. If you have any questions on this point, please contact Mr. John O. Hooson, Environmental Specialist, at FTS 503-429-3299.
3. Any of the alternative management plans in the EIS would be acceptable from the corridor planning standpoint, since none of the plans would adversely affect existing or future designated transmission corridors.

In reply refer to SJ

K-290

1920 Land and Resource Management Planning

Date

JUL 13 1982

Subject: A Proposal for Coordinated Corridor Planning Direction
on NFS Lands in the Western States

To: Regional Foresters, R-1 through R-6

REPLY DUE AUGUST 13

The National Forest Management Act, Federal Land Policy and Management Act, and Mineral Leasing Act of 1920, as amended, address the need for designation and management of utility-transportation corridors on Federal lands.

A 1980 Interagency Agreement between the Forest Service and the Bureau of Land Management, coupled with direction in the NFMA planning regulations, stimulated NFS corridor planning, particularly in the western states. While the mandate to cooperate with BLM and to develop standards and guidelines for designating corridors is understood and accepted, different approaches have been taken, and much good work has been done. For example, in Region 1, the Governor of Montana, Region 1 Regional Forester, and BLM State Director agreed to a joint transportation-utility corridor study within Montana because of mutual State and Federal concern over the effect of corridor planning on public lands and adjacent or surrounding private/State lands. An interagency team then developed planning objectives, analyzed existing right-of-way siting and the management situation and evaluated approaches for corridor identification on Federal lands. Utilities, Federal power marketing agencies, and in-house organizations provided background information, technical review and critique throughout this process.

Our experience including the Region 1 study, leads to several major conclusions which appear applicable Service-wide. They are:

- a. We need to develop uniform effective policies and procedures for managing linear facilities in topographically constrained areas (e.g., mountain passes, river valleys)
- b. Planning for future rights-of-way is an imprecise task. Many variables affect when and where new facilities will be needed. State and Federal agencies alone cannot plan for future rights-of-way or corridors.
- c. Technical compatibility factors are so complex that a case-by-case evaluation is probably necessary after an application for a particular right-of-way is received.
- d. The interrelationships of technical compatibility, environmental, social, land use and resource concerns, and landownership must be considered in corridor planning.

Regional Foresters, R-1 through R-6

2

e. A combination of the direct (where facilities can go) and indirect (where facilities cannot go) approaches to corridor planning and designation present more advantages than disadvantages in meeting both Federal land planning responsibilities and State regulatory role in siting linear facilities.

f. A phased study of interconnected windows, exclusion areas, and avoidance areas appears to be the best method to identify corridors. This approach seems more practical than the designation of long linear corridors, except where existing critical corridors need to be identified and formally designated.

Based on these conclusions, we propose uniform national direction to guide Service-wide planning and decisionmaking for transportation and utility corridors, a copy is enclosed for your consideration. Format will be worked out later, i.e., sequencing into the Directives System. Our aim is to establish direction which clearly answers the following questions:

- How does the Forest Service designate a corridor?
- When does the Forest Service designate a corridor?
- What constitutes corridor designation?

Please review the material and give us your comments and suggestions by August 13, 1982. LMP/WO (Larry Hill) is coordinating development of this direction with WO/Lands and Engineering. Feel free to discuss the proposal with him (382-8013), but we will want your thoughtful comments in writing as well.

R. M. Housley
Deputy Chief

Enclosure

K-291

Proposed Uniform National Direction
for Coordinated Corridor Planning on
National Forest System Lands in the Western States

AUTHORITY.

Principal Authorities. The following statutes provide the primary foundation and guidance for transportation and utility corridor planning.

1. The Forest and Rangeland Renewable Resources Planning Act of 1974, as amended (RPA).

a. Section 6 requires the development, maintenance, and revision of land and resource management plans, and sets forth the principal standards and guidelines that will govern planning and management of the National Forest System

2. The Federal Land Policy and Management Act of 1976 (FLPMA)

a. Section 503 requires the utilization of rights-of-way in common in order to minimize adverse environmental impacts and proliferation of separate rights of way; the Secretary to issue regulations containing the criteria and procedures for use in designating such corridors; and permits any existing corridors may be designated as transportation and utility corridors pursuant to Section 503 without further review.

3. The Mineral Leasing Act of 1920, as amended

a. Title 1 of this Act authorizes the Secretary of the Interior, through the Bureau of Land Management, to grant rights-of-way for oil and gas pipeline across all Federal lands. If the project affects only National Forest System lands, the Forest Service has responsibility for issuing the permit. For projects affecting Federal lands under the jurisdiction of more than one Federal agency, the Secretary of the Interior (with approval of affected agencies), grant a right-of-way over all the involved Federal lands. The Act encourages the utilization of rights-of-way in common to the extent practical.

Related Authorities.

1. 36 CFR 219.10(b)(14),(d)(5), and 36 CFR 219 13(b)(10) and FSM 1920 provide broad management standards and guidelines direction for transportation and utility corridors.

OBJECTIVES. The objectives in applying the following Servicewide direction for transportation and utility corridor planning are to:

1. Avoid the proliferation of separate linear right-of-way corridors.
2. Meet the spirit and intent of existing legislation.

3. Plan and designate corridors on National Forest lands within the land management planning process, with recognition as required of corridor situations and needs on other ownerships and jurisdictions.

4. Insure full coordination between Regions and with Federal and State agencies.

5. Provide consistency between Regions with enough flexibility to handle special and unique problems.

POLICIES. The policies which follow provide guidance for transportation and utility corridor planning and designation in the Forest Service

1. Corridor planning and designation, including rights-of-way siting, will be accomplished through the NFMA planning process, with appropriate emphasis given to intergovernmental and interregional cooperation. As a general rule and consistent with demonstrated need, corridors will be designated in Forest Plans through the assignment of appropriate management prescriptions

2. The identification and selection (designation) of future corridors will be based on the combined window, exclusion area and avoidance area concept as applied through the NFMA planning process. Formal designation of linear corridors depends upon demonstrated public need as exposed during this process.

3. The location of existing transportation-utility facilities may be designated as corridors without further review (FLPMA, Section 503), or addressed for designation through the NFMA planning process consistent with identified public issues, management concerns, and resource use and development opportunities.

4. Regional Foresters will promote development and use of a uniform Federal/State analysis, evaluation, and decisionmaking process for individual rights-of-way proposals under joint jurisdiction of Federal and State agencies in order to achieve interstate consistency in rights-of-way and corridor decisions.

5. To help achieve interstate-interregional coordination and consistency in rights-of-way and corridor planning and decisionmaking, Regional Foresters will promote establishment of joint State/Federal Coordination Committees to review land management plans to assure that corridor goals are achieved. Compatibility at Regional and State boundaries is an essential major goal.

6. A transportation-utility corridor will be considered formally designated when any of the following occurs:

(a) approval of a Regional or Forest Plan, or revision or amendment thereof, which allocates lands to a linear corridor, including "windows", and existing corridors, or absent an approved NFMA plan,

(b) delineation in a special use permit of the exterior boundaries of a right-of-way within which one or more compatible facilities or uses will be permitted

RESPONSIBILITIES. Responsibility for developing specific Regional corridor guidance, within this direction, remains with Regional Foresters. Implementation is accomplished through Forest planning

DEFINITIONS. (to be completed, corridor, window, avoidance and exclusion areas, others, etc)

GENERAL REQUIREMENTS FOR TRANSPORTATION AND UTILITY CORRIDOR PLANNING.

1 The approach used in planning corridors will recognize existing rights-of-way, identify areas with restrictions and provide flexibility in analysis and selection of future corridors. Generally, this approach will be used on a Statewide basis within a Regional Forester's jurisdiction, working directly with the State and other significant Federal land management agencies. The following are the basic components of a corridor designation process

a A Statewide map inventory of present and proposed linear facilities (electrical transmission, fuel transmission, communications, highways, and railroads, canals, ditches, pipelines, etc, see FLPMA Section 501).

b. Documentation of the Statewide corridor situation including an assessment of the linear facilities (e.g., existing and projected linear facilities, technical and engineering compatibility considerations, etc).

c. Development of specific criteria for the identification in Regional or Forest Plans of existing critical rights-of-way, corridor exclusion areas, avoidance areas, and windows. This provides the basis for any actual subsequent designation of a corridor in a Forest Plan

d If appropriate, prepare and execute an agreement or similar coordinating mechanism with the appropriate Governor and BLM State Director, or other appropriate agency head establishing an interagency group which coordinates the application of corridor planning criteria. This group will coordinate planning for specific right-of-way project proposals involving multiagency jurisdiction.

2 The criteria for identifying corridors are designed for application to all lands; however, the USDI-Bureau of Land Management, USDA-Forest Service, and State agencies will only apply the criteria on lands within their jurisdiction. However, application of these criteria by one agency may reflect resource situations and land use situations on other adjacent or nearby jurisdictions. Local governments and other Federal agencies have the option to consider these standards in their planning. These broad criteria are

A. EXISTING RIGHTS-OF-WAY CORRIDORS - Land areas currently occupied by existing transportation-utility facilities. Includes only those which are of critical importance to national or regional commerce, or which have been identified as an issue to be addressed in the NFMA planning process. Examples. See FLPMA Title V, Section 501.

B EXCLUSION AREAS - Land areas determined to be unavailable for corridor allocation or facility siting. Include only those areas with a statutory Congressional mandate that excludes linear facilities, example: National Wilderness Preservation System units.

C. AVOIDANCE AREAS - Land areas that pose particular land use or environmental impacts which would be difficult or impossible to mitigate (May vary by type of facility)

1. Areas where establishment and use of corridors conflict with land use/land management objectives

Examples:

Specialty managed areas, such as areas designated for developed and primitive recreation, research natural areas, environmental education areas.

Environmentally sensitive areas (certain wildlife habitat areas, faults, wetlands, slump areas, etc.)

Archeological and historical sites.

Areas with specific visual objectives which conflict with facility placement.

Active coal mining units

High site timber lands when low site lands are available for rights-of-way.

2 Areas with special or unique values that have been accorded specific and sometimes protected management status through "legislative" action. Facility placement would conflict with these values

Examples:

National Recreation Areas (NRA)

Wild, scenic, and recreational rivers

Nationally classified trails

State recreation areas

3. Areas which through the NEPA scoping process have been identified by local government bodies (within their areas of jurisdiction) as not suitable for the placement of linear facilities

Examples:

Urban residential areas

City parks

D. WINDOWS - Usually short, narrow passageways through constrained areas which are the most feasible potential locations for linear facilities, considering engineering and/or environmental factors.

Examples.

Areas recognized as critical corridor segments because of physiographic or technical suitability

Restricted passages remaining subsequent to allocation of lands for exclusion or avoidance areas.

Existing critical corridor segments through sensitive areas, such as urban, residential areas or areas of intensive land use.

ER 86/1110

Don Smith
Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, Washington 98801

Dear Mr. Smith:

The Department of Interior has reviewed the Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (PLRMP) for the Wenatchee National Forest, Washington. The following comments are provided for use and consideration when preparing the final documents.

Fish and Wildlife Resources

A systematic and conclusive assessment of Forest Plan alternatives was made difficult for the following reasons: (1) There is a lack of detailed biological and forest activity information. (2) Many of the data presented are generalized and do not accurately reflect the potential for individual forest activities to impact biological resources, e.g., road construction was not adequately analyzed according to the sensitivity of the affected resources. (3) There is a lack of a comprehensive range of alternatives, i.e., and it would be helpful if an alternative that maximized fish and wildlife production were not included. Discussion of such an alternative would be very useful for comparison purposes and to present the full range of benefits for a forest that is managed under the concept of multiple use. (4) No clear analysis was presented showing the true net public benefits of the various alternatives. For example, it was not made clear if the sport value of anadromous fish was considered.

Alternative E appears to have the greatest potential of all the presented alternatives for producing the best mix (number of species and number of individuals per species) of sensitive animal/plant species, big game and small game, non-game animals, and anadromous and resident fish. However, even alternative E is not the best designed fish and wildlife plan. It does not include measures that would significantly increase deer and elk populations such as protecting and improving summer and winter range areas. Neither does it protect wildlife from disturbances caused by motorized vehicle (motorcycles and snowmobiles) use over large tracts of areas without roads.

All the environmental impacts to fish and wildlife habitat and mitigation requirements/costs have not been identified in the subject document. Because of this we recommend that the Plan include an intensive monitoring effort to determine if the chosen alternative is working as expected. The Forest Service (FS) should consider the use of two methodologies developed by the Fish and Wildlife Service (FWS). Habitat Evaluation Procedures (HEP) and Instream Flow Incremental Methodology (IFIM). HEP is a method which can be used to document the quality and quantity of available habitat for selected wildlife and fish species. HEP provides information for two general types of fish and wildlife habitat comparisons: (1) the relative value of different areas at the same point in time; and (2) the relative value of the same area at future points in time. By combining the two types of comparisons, the impact of proposed or anticipated land and water use changes on wildlife and fish habitat can be quantified. IFIM can be used to assess aquatic habitat as a function of flow. It is a collection of field techniques, computer models and analytical procedures designed to predict changes in fish habitat due to increments of flow change. It can also be used to evaluate such diverse impacts as changes in channel structure or alterations from a pollution source. In general it can be used to translate changes in land use to changes in stream environment. The use of HEP and IFIM, as well as other carefully designated studies, to monitor how well the chosen Forest Plan works, will substantially reduce the uncertainty surrounding the predictive capabilities of the Plan for protecting fish and wildlife. Use of such monitoring methods would also assist the FS in taking timely corrective actions to activities that would impede meeting fish and wildlife goals on the forest.

The DEIS emphasizes the potential for cumulative environmental impacts due to activities on land of "intermingled owners" (lands that are not owned by the FS but are within or near Forest boundaries) and FS land. This appears to be a fair assessment of the impact situation because the management goals of the intermingled owners appear to dictate a much faster rate of harvest of mature timber than will occur on FS lands. A discussion should be included that shows how the FS plans to modify their cutting plans when the cumulative impacts of logging activities on FS and intermingled lands threaten fish and wildlife resources. A discussion should also cover the feasibility of the FS acquiring intermingled land. This discussion should include FS policy on securing all mineral rights to any land that is acquired by purchase in fee title (preferred for conservation of fish and wildlife resources) or trade. Federal ownership of mineral rights will ensure that the FS has a full range of options for making management decisions that will protect fish and wildlife habitat on any acquired lands.

There is National interest in improving Columbia River anadromous fish runs through, among other things, mitigation of past environmental impacts to fish habitat. The FS should take every precaution to see that the Forest Plan is consistent with positive measures that are being planned and acted upon under legislation such as the Northwest Power Act and the Fish and Wildlife Plan being developed by the Northwest Power Planning Council.

Implications of the Migratory Bird Treaty Act for projects on the Forest should also be considered. The discussion of migratory bird use of the Forest is inadequate. A thorough discussion should be included as to how the FS plans to prevent the destruction, and enhance the habitat, of birds, nests and eggs protected under the Migratory Bird Treaty Act.

Mitigation of potential adverse impacts, from Forest activities, on fish and wildlife needs to be fully considered. It is the policy of the FWS to actively seek to mitigate losses of fish and wildlife habitat as a result of development projects. If FWS is requested to review specific projects/activities that result from the Forest Plan they will apply the

K-295

FWS Mitigation Policy (Federal Register, Vol. 46, No. 15, January 23, 1981; amended February 4, 1981) to those same projects/activities. The overall goal of the Policy is twofold. (1) conserve, protect, and enhance fish and wildlife habitat; and (2) facilitate balanced development of our Nation's natural resources.

Cultural Resources

The Wenatchee Forest Plan and DEIS constitute an impressive, up-to-date summary of the Wenatchee National Forest program for identifying, evaluating, protecting and interpreting to the public its cultural resources. For cultural resource planning beyond the project level, this program may well have potential to serve as a model for other forests. The plan advocates integrating the Wenatchee Forest comprehensive planning goals with those of the Washington State Historic Preservation Office. This approach should result ultimately in the creation of the historic contexts needed to better understand the significance of cultural resource discovered on the forest and, thus, their best possible treatment.

Given the particular relevance of the plan to cultural resource needs that have been identified nationally, the impact of the forest's selection of the "C" management alternative would seem to be properly mitigated. Complete implementation of the Wenatchee cultural resource program would be expected to produce highly desirable results for the Wenatchee National Forest.

National Parks

A review of the maps provided indicates that all alternatives considered propose similar management of areas adjacent to North Cascades National Park and Lake Chelan National Recreation Area. These areas would be classified as WI-1 (wilderness), RE-3 (dispersed recreation), and SI-1 (retention of visual quality along scenic travel routes). Each of the classifications is compatible with and supports the National Park Service (NPS) management objectives for North Cascades National Park and Lake Chelan National Recreation Area.

Page III-29 (Lake Chelan-Sawtooth Wilderness) of the DEIS contains a reference to the "North Cascades National Recreation Area (underlining added)." It appears that this reference should be to the Lake Chelan National Recreation Area. On page III-30 (Glacier Peak Wilderness) there is no mention of the adjacent Lake Chelan National Recreation Area or of North Cascades National Park.

Dispersed recreation is preferable in the zone near the park bounded by the William O. Douglas Wilderness Area on the south, Norse Peak and Crystal Mountain on the north, and the park on the west. More intensive recreation use and development in this zone could impact the Crystal Lakes and Deadwood Lakes areas in the park. Development other than dispersed recreation near this primary park entrance should be limited to the ST-1 prescription, which calls for retention of the visual-quality objective and for retention or enhancement of the viewing and recreation experiences along scenic travel routes.

Wild and Scenic Rivers

One area of concern is the discussion of Wild and Scenic Rivers. The National Park Service is the custodian of the Nationwide Rivers Inventory (NRI), which was conducted under the authority of the Wild and Scenic Rivers Act (W&SRA).

The forest should, as part of the river study process, conduct studies to determine suitability, and deal with those findings in the various alternatives. To further clarify the process of river designation, two enclosures are attached. Attachment 2 is a set of standard terms. The status of rivers as possible candidates for inclusion in the National System of Wild and Scenic Rivers is difficult to determine without terms that are tightly defined; the enclosure is one possible set of standard terms. Attachment 3 is a flow chart of the recommended study process. The chart sets forth a recommended procedure of conducting evaluations that may result in the designation of a river or river reach as a component of the National Wild and Scenic River System, or deletion of it from the NRI or any other management designation imposed by a Federal land management agency. Comments A through E are footnotes to the chart.

Enclosed is a copy of River Recreation in Washington: An Initial Inventory and Assessment (Attachment 4). Pages 112 to 115 and pages 120 to 125 are relevant to the Wenatchee National Forest. Also enclosed are five pages from NPS's computer data bank containing more information than that in the report (Attachment 5), and a separate package (Attachment 6) on River Cultural Values that has been extracted from the parallel Archaeological and Historical Resources, State of Washington, this report parallels the river recreation report.

National Natural Landmarks

Nowhere in the EIS or proposed plan do we find any discussion of National Natural Landmarks (NNLs). There are seven proposed NNLs in the forest. These are Meeks Table, Edwards Plateau, Fish Lake Bog, Thompson Clover, Tumwater, Eldorado Creek and Mount Adams. A discussion of the NNL Program should be included in the plan.

BLM Administered Lands

Based on a review of the maps submitted in the Plan/EIS package, all the alternatives are generally consistent with the BLM proposed management of adjacent public land. The apparent inconsistencies are identified below.

Alternatives A, A/NFMA and H.

1. FS allocations in the No. 1 and No. 2 Canyon areas appear inconsistent with adjacent BLM lands managed primarily for watershed protection. Watershed problems in this area could directly affect Wenatchee and vicinity.
2. BLM lands in the Entiat Valley are primarily managed for range and wildlife. Winter range is an important factor; intensive forest management of adjacent FS lands could adversely affect it.
3. BLM lands north of Lake Chelan are primarily valuable for grazing and wildlife. This area also contains winter range and is not entirely fenced from FS land.

Alternatives B, C, D and I.

1. BLM lands in T.28N., R.21E., Sec. 29 did not have any ORV restrictions designated in the Spokane District proposed Resource Management Plan (August 1985). Topography and access may limit any potential conflict.

Alternatives E and F.

1. Same potential conflict in T 28N , R.21E., Sec 29 as in Alternatives B, C, D and I.
2. The same potential inconsistency with ORV's exists in the Brisky Canyon area.

Water Resources

Sources of drinking water provided to the public and staff on the National Forest should be discussed. If ground water is used, the occurrence of ground water should be described, and precautions to protect ground-water quality should be addressed. The statement and plan should also address the subject of sanitary facilities provided by the National Forest management for recreational and administrative sites, indicating monitoring and any other measures used to protect ground-water and surface-water quality.

Alternative F would appear to preclude the possible enlargement of Bumping Lake if all of the lands surrounding the existing lake were to be formally classified to protect the natural setting. The environmental statement should be modified to discuss the impacts of precluding the enlargement of Bumping Lake including the foreclosure of one of the primary options for providing water for instream flows to enhance runs of salmon and steelhead in the Yakima River basin. Another option would be to modify Alternative F to allow for the possible future enlargement of the lake. The other alternatives appear to adequately allow for the possible enlargement of Bumping Lake.

Mineral Resources

The planning document makes an excellent effort to depict the effects of various alternatives and the Proposed Plan on the availability of lands for mineral entry, and the extent of restrictions imposed on lands that are left available for mineral entry.

However, the document does not consider minerals as a valuable resource to be treated on a par with other resources in the development of the forest plan, and ultimately on the land allocations. The availability of lands for mineral entry and the levels of restriction appear to have been based totally on other resource concerns without due consideration of the effects on mineral exploration and development.

Treatment of mineral potential is confusing due to a lack of clear statement of the terms and the methodology used. The confusion regarding "mineral potential" and "potential for exploration/development/production within 50 years" is pervasive throughout the minerals narrative of the document. Occasionally other terms such as "probable" mineral resource potential compound the confusion. For instance, in the DEIS (Minerals section, page III-85) potential for locatable mineral occurrence is shown in Figure III-11 and Table III-37 with the definition to be given in Table III-37a. However, that table does not describe mineral potential but "Potential for exploration/development/ production within 50 years." It does not follow USGS, BLM or USBM usage of the term mineral potential.

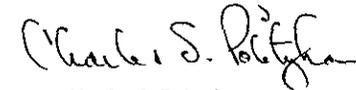

Leasable mineral classification is given in Figure III-12 (page III-93 of the DEIS). The classification is credited to USGS/BLM, but excludes the Known Coal Resource Area determined by those agencies. The KCRA should be shown on Figure III-12.

Areas identified for land disposal (Category IV) include much land which is valuable for coal, oil, and gas, geothermal, and hardrock leasables. An explanation as to how the determination that it would be in the best interests of the public to dispose of these lands was made and whether the mineral estate would be reserved to the Federal Government would be useful to reviewers. This is of concern since it is noted in Chapter II of the plan (p. II-72) that the mineral resources need to be inventoried and since mineral leasing is a source of revenue to the Government.

Our additional comments related to specific portions of the subject documents are attached.

Thank you for the opportunity to review this document.

Sincerely,

Charles S. Polityka
Regional Environmental Officer

Attachment I

U.S. Department of the Interior Specific Comments Related
to the
DES and Proposed Land and Resource Management Plan
for the
Wenatchee National Forest

DEIS

Page III-37, Wildlife The DEIS presents an excellent assessment of affected wildlife species describing unique and special habitats such as old growth, rivers, snags, downed woody material, cliffs and rims, caves and burrows, and talus. It describes the occurrence and status of threatened, endangered and sensitive species in various regions of the forest and explains the establishment of several indicator species for various habitats that are very important for wildlife management.

However, Section IV, the assessment of environmental consequences to wildlife for the Preferred Alternative C (page IV-31) consists of two very short paragraphs, of which only one sentence concerns nongame species. This section needs to be expanded considerably so that it is comparable in detail to the affected environment section.

Page III-42 (d) up to "Northern Spotted Owl". This section includes a listing of forest wildlife that have been listed as "sensitive" by the FS. The FS should be aware that the FWS has published a list of sensitive bird species (September 1985) for Region One of the FWS which includes Washington State. Sensitive species are defined by the FWS as vulnerable or declining species, subspecies, or distinct populations that could become Federally listed as endangered or threatened in the foreseeable future, throughout all or in a significant portion of their ranges without active management or removal of threats. A copy of the FWS sensitive bird list will be provided to the Forest wildlife biologist under separate cover to assist in determining if any of the sensitive bird species use the Forest.

Page III-42 and 43 (d) Northern Spotted Owl. The discussion on spotted owls could be improved. For example the phrase "minimum management requirements" should be explained in terms of viable populations of spotted owls. The National Forest Management Act speaks to managing for viable wildlife populations. As such, any plan must ensure that there are adequate numbers of individual reproductive animals, and that habitat will be well distributed to ensure interaction of individuals within the population.

There appears to be a lack of spotted owl inventories in the past and no formalized plans to do future inventories. The FS should revise and strengthen their policy on spotted owl (and other sensitive, threatened and endangered species) inventory work.

Page III-46, Table III-17 through III-48. The distribution of salmon and steelhead is only generally described. As a result it is difficult to determine how the boundaries and prescriptions of the alternatives will affect fish. A map (similar to the Alternative Maps) that shows fish use and potential fish habitat would be very useful and should be included. Any anadromous fish map that is prepared should show (a) present anadromous fish use according to spawning and rearing areas, (b) potential anadromous fish habitat (juveniles and adults), (c) natural and artificial fish barriers, and (d) areas where data gaps exist.

Page III-47, Paragraph 3. It is correctly indicated that mainstream Columbia River hydroelectric dams have been and still are a major factor in limiting anadromous fish production. However, the situation is changing. Anadromous fish runs in the Columbia River have been improving (e.g., spring chinook and steelhead runs). This is due to a number of factors such as better transportation measures for smolts, improved hatchery practices, and better harvest management of the sport and commercial fisheries.

Aquatic habitat on the forest is an essential part of the habitat base that will eventually be required for expanding Columbia River fish production. Fishery resource managers are optimistic for improvement in Columbia Basin anadromous fish runs due to the recently ratified United States/Canada Pacific Salmon Treaty. It is expected that improvement in the runs will continue. Thus, all existing and potential anadromous fish habitat in the forest should be maintained in its present state or improved. This includes stringent protection for riparian zones. Concerted efforts should be made to restore all aquatic habitat on the forest that is presently in a less than optimal or deteriorated state due to past logging, grazing and mining activities.

Page III-49(e) Fisheries Habitat. Field inventories of fish habitat have not been completed for the Forest. The final EIS should include a detailed discussion on how and when this task will be completed. Such a discussion should indicate standardization of measuring units, sampling methods and timing, definitions of terms, criteria (e.g., criteria for defining cover), classification systems, cartographic scales, and data reduction procedures necessary to permit comparisons of different areas over time.

Page III-53 (12). It is correctly stated that "the main barriers, Keechelus, Kachess, Bumping, Cle Elum, Tieton and Clear Lake Dams have significantly reduced the access of anadromous fish to forest streams. Over 100 miles of previously utilized anadromous streams have been affected. These dams resulted in the complete loss of sockeye salmon in the Yakima system." A detailed discussion should be included in the final environmental impact statement as to the FS's goals for protecting anadromous and resident fish habitat (of the forest) from the adverse effects of future dam construction. In addition, it would be helpful if a detailed discussion was included on how each of the existing dam and reservoir complexes, involving forest lands, could be improved for anadromous and resident fish production. In this regard the FS may wish to include data from a joint FS and FWS anadromous fish habitat survey of the Cle Elum watershed conducted in 1980.

Page III-67, last paragraph. Cattle are presently allowed to compete with elk on elk calving grounds of the Table Mountain Allotment. Cattle compete with elk not only for physical space but for nutritional plant species utilized by elk during periods of gestation and lactation. The Final EIS should present a plan that will eliminate or substantially reduce this problem.

Page III-89. The mineral potential map located on page III-89 of the DEIS should be enlarged to the same scale as the color alternative maps. This would allow the reader to easily compare the effects each alternative would have on areas of varying mineral potential, particularly the areas about which the reader would have specific concerns. In addition, we request that the computer-generated maps which demonstrated proposed management practice on areas of mineral potential be included in the report. Bureau of Mines received these from the Minerals and Geology staff of the Forest. They provided valuable information not available anywhere else.

Page III-90. Additional categories for Table III-37a - Criteria/Parameters for Economic Mineral Evaluation would be useful. Table J-3 in the Wallowa-Whitman National Forest

plan is almost the same, yet it provides two more categories of mineral potential—moderately high and very low. Access categories as used by the Beaverhead National Forest, Montana, also provide additional detail not available in the Wenatchee Forest tables without research. (See Attachment 6)

Page III-95 of the DEIS. The Water and Power Resources Service is now called the Bureau of Reclamation. The names in the table and narrative should be corrected.

Page III-116, Interactions with other Resources. The section on minerals and related sections, indexed and located on page III-153 of the DEIS, was especially useful. This is a remarkable discussion and a technique to be recommended for other forest plans

Page IV-29 Environmental Consequences. Cumulative impacts are not adequately addressed for the following reasons: (1) With the exception of deer and elk, we could not find an adequate analysis of cumulative environmental impacts on wildlife for each of the alternatives. Even for deer and elk a number of questions were not addressed, e.g., were the effects of lost soil productivity on valuable deer and elk winter range included in the analysis? see DEIS IV-29 through IV-32(c). (2) The cumulative impacts of each alternative on fish habitat was not quantified, e.g., number of stream miles adversely impacted by logging and grazing activities see DEIS page IV-32(7) through IV-40(b-7). (3) The analysis should evaluate the cumulative effects of not only FS activities, but also the activities of other public and private entities within, and outside of, the National Forests. (4) The analysis should have considered the effects of the forest, and activities therein, on the Columbia Basin as a whole with respect to fish and wildlife resources and their use. There are 16 National Forests in the Columbia Basin that produce anadromous fish, migratory birds and other resident fish and wildlife species. All of these forests are going through a major forest planning process that will ultimately determine how the forests are to be managed. Human activities on these forests can have a profound effect on fish and wildlife resources of the Basin. This is well illustrated by the fact that 50 to 70 percent of all remaining anadromous fish habitat in the Basin is contained in these forests. Actual and potential Columbia River anadromous fish production will be reduced to the degree that the aforementioned habitat base is impacted. Anadromous fish production downstream of forest boundaries will also be affected negatively or positively by water quality, quantity and timing of waterflows that originate on those forests. (5) The analysis did not adequately cover a broad enough time frame. In general, the impact analysis begins with current trends and continues through the fifth decade. It is not clear if past forest impacts were included or excluded, or at best used as some sort of baseline condition that included current trends. A careful integration of past environmental impacts into the cumulative impact assessment is an important step in developing a complete document. Columbia Basin fish and wildlife habitat has changed dramatically in the past 70+ years. Dams, water flow manipulation and depletions, various watershed management practices of agriculture and forestry, urbanization, industrialization, pollution and various transportation systems have resulted in huge changes in the aquatic ecosystems of the Columbia Basin.

Page IV-40 (c). The statement is made "no conflicts are anticipated between the effects of the alternatives and other plan and policies for the fisheries resources... . Since all alternatives predict increases in fish habitat capability, implementation of any alternative should be compatible with other plans." The use of any one of the presented alternatives could potentially interfere with efforts to restore anadromous fish runs to the Columbia Basin. For example, *livestock grazing on the forest could severely impact the major components of a stream ecosystem*: (a) streamside vegetation which provides shade and cover for fish and supports insects that are used as fish food, (b) stream channel morphology, (c) quantity and quality of the water, and (d) structure of the

streambank which is where undercut banks are formed that in turn provide valuable fish cover.

Page IV-40 (d) The EW-2 Riparian Protection Zone Prescription. A highly detailed discussion of how the FS plans to log the riparian zone is needed. It would also be helpful if an example was included of a typical logging operation where there was work in the riparian zone. We are particularly concerned about how those activities will impact fish and wildlife resources such as anadromous salmonids, resident fish, grouse, deer, and elk

Page IV-79. The tables on pages IV-79 through IV-85 are excellent, however, the Bureau of Mines has suggested a format that provides additional detail for an easier comparison of alternatives. (See Attachment 7)

Page IV-137. Protection of trust resources of the Yakima Tribe would best be served by *Alternative E*. This alternative appears to have the least adverse impact to soils, water, and cultural resources and be highly beneficial to the fisheries. There is some possibility that a lower allowable cut in the Wenatchee would lead to increased competition for reservation timber. While this might economically benefit the Tribe it would also increase the potential for detrimental impacts to reservation fish and wildlife resources.

Page IV-140 Summary of the Relationship Between Short-Term Uses and Long-Term Productivity. This section fails to discuss the many unavoidable adverse impacts that will occur to fish and wildlife habitat (chemical, physical and biological) from the preferred alternative or any of the other presented alternatives. For instance (as indicated on Pages IV-74, 75), most lands having less than a 40 percent side slope will be harvested by some form of ground-skidding equipment. Multiple trips over a piece of ground with a rubber-tired or even track-type tractor can cause soil compaction. The effects of soil compaction tend to be long lasting (more than one decade, as indicated on page IV-74) and they are often additive with each succeeding entry. In addition to reducing soil productivity, soil compaction also reduces the water infiltration rate so that there will be accelerated runoff, thus producing delivered sediment that can impact fish life.

The document indicates that other forest activities besides logging could have long-term consequences to forest productivity of fish and wildlife resources. On page III-85 it is stated "The Forest Service recognizes that minerals are fundamental to the nation's well being and as a policy it encourages the exploration for and the development of the mineral resources it manages." Thus it is reasonable to assume that substantial mining activities could occur in the forest in the future. Toxic materials commonly released by mining are arsenic, cadmium, cobalt, copper, iron, lead, manganese, mercury, nickel and zinc. Fish mortality can result from exposure to these metals in high concentrations. Continuous exposure to low levels of the metals may produce chronic effects such as behavioral changes, reproduction failure or juvenile mortality. Fish may avoid whole stream sections that are polluted with metals.

Proposed Land and Resource Management Plan (PLRMP)

Page II-8. There appears to be some inconsistencies with regard to river studies/designation. Page II-8 of the PLRMP states that the Chiwana, White, Wenatchee, North Fork Entiat, Entiat (two segments) and Mad (two segments) have been determined to be eligible and suitable under the Wild and Scenic Rivers Act. In the Appendix (page B-141), the Chiwana, White and portions of the Wenatchee Rivers are recommended for further study. Again, page IV-34 of the PLRMP states that steps will be taken to

formally designate segments of the Chiwana, White and Wenatchee Rivers. It appears that additional studies are not necessary, and we would encourage you to follow through on the recommendations on page IV-34.

Page II-51 Land Status. This describes state and private inholdings but not intermingled and adjacent Federal lands. We believe it would be appropriate, to clarify the land patterns, to mention lands managed by the NPS and the BLM, both here and in the DEIS, pages III-3 and 4.

Page IV-71 E through IV-113, 1st paragraph, Forest Wide Standards and Guidelines. The Standards and Guidelines that affect fish and wildlife are inadequate in that they do not provide the detail that will be necessary for on-the-ground guidance to FS personnel. For instance no standards are presented for road construction with respect to fish habitat requirements (See page IV-90). Standards for livestock grazing are not designed so that fish and wildlife habitat will be protected, e.g., no specified protection of riparian zone vegetation and streambank integrity.

Page IV-120. It is not clear how deer, elk, and mountain goat winter and summer range will be managed. Also management prescriptions should be strengthened by presenting a detailed discussion on how important fall and spring range for big game will be managed.

Page V-3 through V-30, Monitoring and Evaluation Plan. The monitoring plan, as presented, is inadequate and appears to be understated for fish and wildlife. Monitoring approaches and techniques are not specified. It appears that the FS plans to rely on other agencies for on-the-ground anadromous fish information. In our view, through Sec. 2, No. 6, NFMA, the FS has a responsibility and an opportunity for leadership in managing forest lands and associated natural resources. A thorough discussion should be included in the document on both the adequacy and appropriateness of relying heavily on other agencies for fishery work on immense tracts of Federal lands such as the Wenatchee National Forest.

Appendices

Appendix C. The discussion on mineral potential for each roadless area was excellent but it would be most easily understood by the average reader if the text was supported with a map.

Page C-215. The statement is made "There are 6,996 acres of private lands within the area belonging to the Burlington Northern Railroad Company. A discussion needs to be included about how the FS plans to maintain public fish and wildlife values of the forest in this or any other potential land trade.

Attachment 2

RIVER TERMINOLOGY

- 1 Potential Rivers. Rivers on the National Rivers Inventory, as well as those identified by the Forest Service as having "potential" for designation as Wild and Scenic Rivers, which flow partly or wholly through the Forest. These may or may not include rivers formally designated as "potential" by the Secretaries of Agriculture and the Interior under Section 5(d) of the W&SRA.
- 2 Eligible Rivers. Those rivers found to be eligible for Wild and Scenic status according to resource considerations and in accordance with the Final Revised Guidelines for Eligibility, Federal Register, Vol 47, no 173, September 7, 1982. NRI rivers are not automatically eligible.
- 3 Suitable Rivers. Those eligible rivers found to be suitable for recommendation to Congress as a component of the National Wild and Scenic River System. Such a determination would be conducted only on rivers that are eligible. While there are no nationally recognized guidelines for a suitability determination, the following should be considered: the amount of private land and its use, state and local government as well as public interest, and cost involved. In other words, the eligibility study considers the resources, and the suitability study includes political, economic, and public interest considerations.
4. Study Rivers. Those rivers formally designated by Congress to be studied under Sections 5(a) and 5(b) of the W&SRA. Only one stream in the Pacific Northwest the North Umpqua, is currently in this category.
5. Recommended Rivers. Those rivers which are found to be eligible and suitable, and which are recommended to Congress to become components of the National Wild and Scenic River System. In the past such a recommendation has usually been made only after Congress first directed that a study be made under provisions of Sections 5(a) and 5(b) of the W&SRA. However, this does not preclude agency-initiated studies.
- 6 Wild and Scenic Rivers. Those rivers so designated by Congress under Section 3(a) of the W&SRA.

Wenatchee, Washington 98801

Dear Mr. Smith

SUBJECT DRAFT ENVIRONMENTAL IMPACT STATEMENT (DEIS) AND PROPOSED LAND AND RESOURCE MANAGEMENT PLAN FOR THE WENATCHEE NATIONAL FOREST, CHELAN, KITTITAS, AND YAKIMA COUNTIES, WASHINGTON (ER 86/1110)

Enclosed is a copy of the letter we sent to the Department of the Interior on the review of the Wenatchee National Forest DEIS and Proposed Land and Resource Management Plan.

The maps attached to your letter of July 18, 1986, were excellent. Maps of this kind included in the EIS are essential for those readers who wish to understand mineral resource potential, how these resources will be managed, and how this management is related to the management of other resources. We cannot provide input with regard to areas of mineral resource potential at this time. We are planning to provide you with this data in the future and hopefully will be able to compensate with quality. It is our desire to assist the Forest Service Minerals and Geology staff in every possible way to assure the most equitable management of mineral resources on Federal land within the limitations of time and manpower.

Please contact this office should any questions on our review of the EIS arise or if you need any assistance with mineral information.

Sincerely,

D'Arcy P. Banister, Supervisor
Minerals Involvement Section
Branch of Engineering Studies

Memorandum

To State Director, Oregon State Office, Bureau of Land Management, Portland, Oregon

From Supervisor, Minerals Involvement Section, Branch of Engineering Studies

Subject Review of Draft Environmental Impact Statement and Proposed Land and Resource Management Plan for the Wenatchee National Forest, Chelan, Kittitas, and Yakima Counties, Washington (ER 86/1110)

Thank you for the prompt response to our letter of July 3, 1986, requesting unabbreviated versions of the DEIS and Proposed Land and Resource Management Plan. We have completed our review and found your plan and DEIS to be excellent and one of the most comprehensive with regard to minerals we have reviewed. Although all of the points we feel necessary were addressed, we do have a few requests and suggestions. They are

1. Enlarge the mineral potential map located on page III-89 of the DEIS to the same scale as the color alternative maps. This would allow the reader to easily compare the effects each alternative would have on areas of varying mineral potential, particularly the areas about which the reader would have specific concerns. In addition, we request that the computer-generated maps which demonstrated proposed management practice on areas of mineral potential be included in the report. We received these from the Minerals and Geology staff of the Forest and feel they would provide valuable information not available anywhere else.
2. Illustrate mineral potential for each roadless area in the appendices. The discussion in the text was excellent but it would be most easily understood by the average reader if the text was supported with a map.
3. The tables on pages IV-79 through IV-85 are excellent; however, we feel they could be substituted by the following table.

Potential Category*	Acreage	Alternative 1 % acres affected (by access category**)				Alternatives 2, 3, 4, etc.
		A	B	C	D	
I						
II						
III						
IV						
V						
Total of forest						

* Same as page J-10, appendices, Wallowa-Whitman National Forest DEIS (enclosed).
 **Same as Beaverhead National Forest, Montana, Revised DEIS (enclosed). This format will provide additional detail and an easier comparison of alternatives.

4. Provide additional categories for table III-37a-Criteria/Parameters for Economic Mineral Evaluation.

The enclosed table for the Wallowa-Whitman National Forest is almost the same, yet it provides two more categories of mineral potential--moderately high and very low. Access categories as used by the Beaverhead National Forest, Montana (enclosed) again provide additional detail not available in your tables without research.

We feel implementation of our suggestions will provide added detail and understanding for the reader.

We offer special congratulations on your "Interactions with other Resources" sections. The section on minerals and related sections are indexed and located on III-153 of the DEIS. This is a remarkable discussion and a technique we will recommend to all of the other forests we review.

Sincerely,

Darcy Bahister
 Darcy Bahister, Supervisor
 Minerals Involvement Section
 Branch of Engineering Studies

Re: Draft Environmental Impact Statement (DEIS) for the proposed
Land and Resource Management Plan, Wenatchee National Forest

Dear Mr. Smith:

The National Marine Fisheries Service has reviewed the subject
draft environmental impact statement

In order to provide as timely a response to your request for
comments as possible, we are submitting the enclosed comments to
you directly, in parallel with their transmittal to the
Department of Commerce for incorporation in the Departmental
response. These comments represent the views of the National
Marine Fisheries Service. The formal, consolidated views of the
Department should reach you shortly.

If you have questions concerning our draft comments, please
contact Jim Esch (503) 230-5427 or PTS 429-5427. Your continuing
coordination efforts are appreciated

Sincerely,

General Comments

The professional fish and wildlife staff on the Wenatchee National Forest should be commended for their effort to accurately represent all natural resource issues in the DEIS. However, there is a common theme in the DEIS and Plan that on-forest habitat greatly exceeds its present use, and that this fact is mainly due to off-forest impacts. Similar forest planning documents that NMFS has already reviewed in Oregon, Washington and Idaho contained this same common theme. This attitude on off-forest impacts tends to down-play the sometimes serious fish habitat degradation that we have observed on national forest lands throughout the region. Logging, road building, livestock grazing, and other permitted activities on the National Forests need to share the responsibility for the present depressed state of the Columbia River Basin's salmon and steelhead stocks.

The National Forests also need to take a more tangible approach in their evaluation of land management activities and their effect on production of anadromous fish. There are always going to be losses due to existing main-stem hydroelectric projects and problems due to harvest inequities. The National Forests should recognize that man-caused mortality will always influence, to some degree, the numbers of fish that can be produced on tributaries to the Columbia River.

The National Forests provide the majority of the available habitat for natural fish production in the Columbia River Basin. It is our hope that the Forest Service will concentrate its management effort on strengthening its role as steward of this anadromous fish habitat. Existing habitat must be protected and degraded habitat improved if long range fishery production goals are to be realized.

We offer the following specific comments on the DEIS and Plan

Specific Comments

Proposed Land and Resource Management Plan

Page II-23, paragraph 4. The text indicates that anadromous fish runs have declined solely due to commercial fishing, irrigation and mainstem Columbia River dams. We suggest that you include factors permitted on the Forest that have also contributed to this decline such as logging, grazing, road building, etc.

Page II-24, Production Potential. The information presented here needs to be supported with additional detail. For example, the coho production estimate appears to be out of line with previous estimates. In the context of the forest planning process, it may be more appropriate to estimate present and future maximum

K-304

potential fish production only on lands administered by the National Forest Service. Also, please provide details of the derivation of the catch and harvest data in the table on the bottom of page II-24

Page II-65, Table II-25 Harvest information is presented under the heading "Fisheries". The methods used to derive these figures should be detailed in the text.

Page II-70, "Fisheries". Given the identified information gaps in the fishery data base the final Plan should discuss whether confidence limits can be placed on the fishery estimates made in the Plan and the DEIS. It is stated that a methodology needs to be developed to address these data gaps in the fishery data base. We propose that the Plan is the proper place to develop this methodology, and suggest that the final Plan include a formula and schedule for gathering this information.

Page III-5, paragraph 4. Best Management Practices (BMP) are referred to but are not explained or detailed anywhere in the plan. The final plan should contain a reprint of the BMP's, possibly as an appendix of the Plan.

Page IV-12, "Fisheries". In the sixth paragraph under this heading, it is stated that most private in-holdings will be clear-cut within 10 years. We suggest that the same planning criteria applied to National Forest lands be used to analyze the effects of this timber harvest on Forest goals and management activities.

Page IV-25, Table IV-1 The table needs some clarification. The final plan should clarify whether the thousands of pounds of harvest for Habitat Improvement is in addition to the commercial harvest. Also, chinook salmon appear to be rather stable in numbers through the year 2035 (Page IV-26). Yet the previous page of the table showed over a sevenfold increase in pounds harvested over the same time period. This discrepancy should either be explained or corrected in the final plan.

Page IV-89, Wildlife and Fish. We suggest that projects be prioritized on the basis of their importance or potential importance as habitat for fish and wildlife rather than just their cost effectiveness.

Page V-14, Monitoring Plan. Please explain what smolt habitat capability is. Also, we recommend that there be consistency between the monitoring plan and the other previous displays of forest outputs. Earlier in the document, units of adult fish or thousand pounds of harvest were used. In this table the unit is smolt production. It is difficult to make a comparison of alternative actions when units of measure are not consistent throughout the Plan.

Draft Environmental Impact Statement

Page II-156, Economic Values. The economic indicator for anadromous fish is described as "commercial harvest of anadromous fish." While commercial harvest is an important contributor to the National economy, other values can be assigned for recreational fishing. For some species of anadromous fish, this sport harvest is a major factor in their dollar value, and may increase in the future.

Page III-46, Anadromous fish. Some part of the decline in anadromous fish numbers should be attributed to land use practices on the Forest.

Page III-47, paragraph 1. The FEIS should explain how smolt habitat capability is calculated

Page III-47, paragraph 5. The June 1982 NOAA Technical Memorandum, NMFS, F/NWR3, Net Economic Values for Salmon and Steelhead from the Columbia River System is cited as the source for harvest distribution data for anadromous fish spawned on the Forest. This report is now outdated. Enclosed with our comments is the latest effort by NMFS to provide economic information for resource planners.

Page IV-122 and 123, Fisheries Interactions-Trees. The discussion here deals with options for the use of funds available for fish habitat improvement. A suggested use of Knutson-Vanderburg Act funds is road culvert fish passage restoration. We recommend that culverts improperly designed or installed be replaced with funds other than those earmarked for habitat work.

Page IV-123, paragraph 2. It is suggested here that timber harvest along stream corridors may increase fish production due to warming effects. We offer that many factors, in addition to temperature, limit productivity in anadromous fish streams. We recommend that the potential benefits of temperature elevation be carefully weighed against the possibility for excessive heating, decreased summer streamflow, and increased sedimentation. Generally, we view an undisturbed riparian zone to be optimal for fish production.

Mr. Doug Rushton
Department of Ecology
St. Martins Campus
Olympia, Washington 98504

Dear Mr. Rushton

Draft Management Plan for
Wenatchee National Forest

We have reviewed the four documents, plus maps, that constitute a draft management plan for Wenatchee National Forest. In aggregate, the reports contain excellent qualitative narrative on the status of Pacific salmon resources and the inter-relationships with planned activities on the Forest. However, we can only judge the plan to be deficient since it does not establish any quantitative technical linkage between salmon production and proposed major environmental modifications. The plan concedes that many activities - timber harvest, recreation, livestock grazing, road management, fire management, small hydroelectric projects, irrigation impoundments - can alter the quality and quantity of available fish habitats. The plan also discusses the distinct possibilities of significant adverse impacts due to cumulative effects and frequently mentions the higher risks of damage as levels of various planned activities increase.

Unfortunately, none of these factors are ever translated into measurable predicted impacts on salmon resources. The inherent assumption is that habitat capabilities can be at least maintained under any configuration of the proposed alternatives. Knutson-Vandenburg (K-V) funding, which is directly related to timber sales, is treated as "enhancement" even though the plan admits that a significant amount needs to be diverted to projects such as inadequate culverts resulting from past activities on the Forest. We believe that the most optimistic possible forecast would be for the future K-V funds to cover normal mitigation practices as these new environmental modifications occur. Special appropriations should be requested to mitigate for past damages which are described in the plan. Many mitigation needs are long overdue. In addition, it is not realistic to expect K-V funds to handle any environmental events such as a major slide or stream channel change due to their limited amount and constraint to the vicinity of timber sales. A single massive slide in a major salmon production area could make all the plan's forecasts obsolete. Again, the

K-306

DEPARTMENT OF FISHERIES
00580

86 SEP -8 A7 46

Mr. Don Rushton
September 3, 1986
Page 2

00580

plan should prescribe the need for special appropriations to handle these types of problems. If all of the above can be successfully incorporated into a revised plan, then outputs from any additional appropriations might be legitimately described as potential fisheries "enhancement". We also propose that any special funding needs become part of the Forest's preferred alternative instead of being linked to other options since the current connection to Alternative E appears to be only coincidental (e.g. "E" shows the highest at \$200,000, "C" shows only \$25,000). We have appended specific comments on a section-by-section basis mainly to support the general conclusion reached above. These begin with the Appendices to the Draft Environmental Impact Statement (DEIS) (600 pages), followed by the DEIS itself (550 pages) and the Proposed Forest Plan (350 pages). (Note: I have not attempted to reference a similar concern each time it appeared.) However, we must stress that it will be impossible to have any meaningful input on the plan until it is revised to establish a quantified relationship between levels of environmental modifications and salmon production. Alternatively, the plan could be revised to document the lack of use of such a relationship in spite of the weight of scientific evidence which supports its existence. A procedure to develop this relationship and implement the needed levels of mitigation would be included. A third option would be to set an overall provisional mitigation level for funding that is directly proportional to the amount of forest area disturbed. A final possibility to consider would be special treatment of anadromous fish (salmon and steelhead) via a separate, supplemental EIS process, possibly for all Forests in the Columbia Basin. Reasons for this approach would be (1) the present inability to quantify impacts from environmental disturbance, (2) the special status of treaty Indian fishing rights, and (3) the cumulative effects of multiple forest management plans on overall Columbia River fish production.

Sincerely,

Sam Wright
Senior Fisheries Research Scientist

SW rc

DETAILED COMMENTS ON THE PROPOSED
WENATCHEE NATIONAL FOREST PLAN

Appendices - Draft Environmental Impact Statement

Page A-9 It is probable that naturally produced salmon resources will be managed for maximum sustained yield (MSY) which is not synonymous with full habitat utilization. The latter would equate to equilibrium yield in the absence of fishing.

The provision of higher water temperatures may be a benefit in some stream reaches, but can eventually create high temperature problems as the same water moves downstream. In addition, higher summer temperature benefits can be at the expense of winter rearing habitat conditions. These potential trade-offs should be added to the narrative.

Page A-19 Under opportunities for No. 7 (Wildlife and Fish), the cooperation should be extended to all entities with fisheries resource management responsibilities.

Page B-62 The modified Universal Soil Loss Equation (USLE) originated as a predictor of soil loss from tilled agricultural lands. Its modification for use in the Forest requires an extrapolation outside the available data base. At best, the results should be portrayed as relative index changes between alternatives. However, the specific methodology questions will remain irrelevant unless the plan develops a quantified technical link between sedimentation and salmon production.

Page B-63 Predicted changes in water yields should also be treated as a rough index since they are based only on vegetative manipulations by silvicultural prescriptions. Probable changes in peak flows and minimum flows are not analyzed. As is the case with sediments, many subsequent discussions treat both factors as absolutes.

Pages B-66 to 83 The economic techniques for salmon resources are difficult to understand. The second full paragraph on page B-66 plus the discussion under "Wildlife Habitat and Diversity" on page B-67 indicate that priced values are limited to recreational uses on the forest and ex-vessel commercial fishery values. Table B-IV-2 on page B-82 and the second paragraph on Page B-83 indicate the same illogical treatment. If this is the case, modification will be necessary to reflect true national values.

Page B-159 Table B-VIII-1 begins to unveil the primary problem in the draft plan. Water yields and sediments are really only indexes, the former by the plan's own definition. The Anadromous Fish Commercial Harvest shows only a very slight difference between nine alternatives, ranging from 63 to 66 thousand pounds. Alternative E shows the highest level, but this is not linked in any manner to its lowest index value for both increased water yields and sediments.

Pages B-184-185 The increases for anadromous fish are unrelated to any of the environmental manipulation differences in the nine alternatives. They will mainly be the result of non-Forest Service actions except for an increment attributable to appropriated habitat enhancement funding that varies by alternative.

Draft Environmental Impact Statement

Page 5-8: As the summary for Alternative E states, it has the distinct negative features of lowest timber harvest, least mineral resource area activity, least payments to counties, lowest employment and lowest income. This makes it an especially poor place to coincidentally propose the highest level of appropriated funds for fisheries enhancement (which is the only reason for Alternative E's highest ranking for anadromous fish production).

Page III-45 The conversion of actual fishery trips to recreation visitor days means that the values in Table B-IV-2 (page B-82 of the Appendices) are unrealistically low. At these levels, the values would fall far below any of the contemporary economic valuations for Pacific salmon benefits in the Pacific Northwest.

Page III-47: As stated in the draft plan, all of the estimates for salmon production will have to be updated. The current goal of the Northwest Power Planning Council is to achieve a survival rate of 90 percent for smolts at each dam. However, recent attempts to increase this goal were unsuccessful, and any assumption that off-Forest Dam losses will be nearly eliminated is unrealistic. The ability of spring chinook to rebuild to MSY will depend mainly upon their inherent reproductive capability and its relationship to the cumulative population removal rate from dam losses plus catch and non-catch fishing mortalities. This reproductive capability can be significantly altered by the quality of spawning and rearing habitat. Amount of rearing habitat (quantity) will determine the maximum production potential.

Page III-53 Fish passage must include not only the commonly-referenced upstream movement of adults and downstream migration of smolts, but also the ability of rearing juveniles to move freely between preferred habitats during their early life history stages. This is particularly critical for fish such as spring chinook, which have prolonged freshwater rearing periods and often move upstream as juveniles.

Page III-54 The inventory and funding priority discussion for habitat improvements illustrate a basic flaw in the draft plan, e.g., there will always be extensive time periods between identification and correction of fish habitat problems on the Forest. Significant fish production losses, possibly irreversible, would occur during these delays. Problems arising from environmental modifications on the Forest must be corrected as they occur, and the inventory and funding mechanisms in the plan need to be revised accordingly.

Page IV-32 The conclusion that the Forest's fish production capabilities would increase under any alternative is far too optimistic, since no losses of any type are calculated for environmental disturbance activities such as timber harvest, associated road building and grazing. Funding for fisheries work is treated as enhancement only, even though much of it would be diverted to problems created from past Forest management practices. The plan does not acknowledge any major risk of future environmental damage exhausting the available funding sources.

Page IV-33 The figures for appropriated funds in Table IV-11 do not appear to have any direct relationship to components of the nine alternatives. It appears that the peak amount of \$200,000 in Alternative E could just as easily be included with the preferred Alternative (C).

Page IV-38 Several alternatives would include the diversion of K-V funds to provide fishing access. This would further diminish the availability of these relatively modest funds for correcting past environmental damage on the forest and fulfilling newly emerging needs in a timely manner.

Page IV-72 Delivered sediment is correctly described as only an index in this section, with the analysis value being limited to relative differences between alternatives. Other parts of the draft plan treat predicted sediments as total expectations. Unfortunately, the sediment index shows long-term increases for every possible alternative. This is incongruous with the forecast of no net adverse impacts on the fish resources due to Forest activities.

Page IV-122 The word "enhancement" is continually mis-used throughout the draft plan. In virtually all cases, the available funds will actually be utilized for mitigation of past or current habitat damage on the Forest. Some projects, such as spawning channels, may appear on the surface to be enhancement, but in reality will probably be comparable to the plan's earlier example of a post-fire salmon spawning channel on the Entiat River.

Page IV-124 The inter-action between fisheries and water should include the negative aspects of higher peak flows and lower minimum flows, which are not a part of the calculated index values. The section on fisheries and soil contains one of the many narrative descriptions which concede the significantly greater risk of damage to fish resources from certain alternatives. Unfortunately, these numerous greater risks are never translated into quantified lower long-term forecasts for salmon habitat capabilities. Another good example of higher risk is in the fisheries-road inter-actions.

Proposed Land and Resource Management Plan

Page IV-96 Other descriptions for the Class III streams indicate that any with fish potential would be included. However, this description limits inclusion to streams that are rehabilitated or enhanced. The broader definition is much better, since the absence of fish can also be due to inadequate spawning populations or recent fish passage problems - both correctable problems.

Pages V-14 and V-15 Several entries under Fish should be revised. Actual juvenile spring chinook abundance per standardized unit of habitat area should be measured and compared with MSY production abundance needs. Successful production will depend upon a full year of adequate habitat conditions, which can best be measured by the fish themselves. The variability which would initiate further evaluation should parallel the plan's forecast of continual abundance increases. For fisheries mitigation (improvement), the critical measures should involve correction of all critical areas in a timely manner in order to minimize production losses. The same need applies to migration obstacles.

Page A-15 and A-16 This table clearly illustrates the problem of delayed mitigation of fisheries resource damages. The plan, in its current form, must phase-in correction of past problems due to the limited and uncertain availability of funding. No reserve of any type is provided for new problems that arise. These would presumably be added to the list for correction at some dates far in the future.

00579

September 22, 1986

Mr. Don Smith, Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, Washington 98801

Dear Mr. Smith

Governor Booth Gardner has delegated review and coordination of comments on National Environmental Policy Act documents to the Washington Department of Ecology. This letter is the response of the state of Washington to the Wenatchee National Forest's Proposed Land and Resources Management Plan and Draft Environmental Impact Statement. We appreciate the opportunity to provide comments and assist in your efforts to develop a workable Plan for managing the Wenatchee's valuable resources.

Since each alternative favors a different mix of resources and resource values, the "preferred alternative" would hinge upon one's perspective of resource management. Therefore, due to the broad nature of interests and the range of mandates represented by the various state agencies, there is no "preferred alternative". Rather, we have taken the approach of discussing the alternatives that are presented in the Plan, emphasizing evaluation of the preferred alternative. Three areas of special concern were identified. Detailed comments and suggestions regarding these areas are included in the enclosures.

- 1 The descriptions and analyses of water quality and related elements are disconcerting in that no degradation is promised even though the data and information provided indicate otherwise. For example, sedimentation is increasing over the life of the Plan, but at the same time water quality and anadromous fish production are supposed to increase; a relationship contrary to our experience.
- 2 There is a need for basic data in several areas; e.g., baseline information on fish populations and habitat. As a corollary to the need for basic data, monitoring and evaluation of past, present, and future management activities should be implemented. (Specific examples of data needs and monitoring/evaluation needs are included in the enclosures).

- 3 Washington State contains all or part of seven National Forests. We reserve the opportunity to examine the cumulative effects of all the Forest Plans once they are completed and at that time additional comments may be submitted regarding the Wenatchee Plan.

In Ecology's role as coordinator for this Plan, we received comment letters from state agencies and those letters are included as enclosures to this letter. Please refer to those letters for specific, detailed comments and for inclusion in your final plan.

We congratulate you and your staff for your good work thus far to complete this important planning effort.

Sincerely,

Andrea Beatty Rifiker
Director

I AIR QUALITY

- K-311
- A. The state's primary concerns with regard to air quality maintenance are centered upon the recently revised "Smoke Management Plan" and the visibility standards that are included in it. In general, the discussion included in the DEIS and the Plan adequately cover the state concerns.
- B. The cumulative and synergistic impacts of Forest Service burning and confinement fire policy needs to be examined in conjunction with the agricultural burning by farmers and orchardists [especially in the spring] and prescribed burning and wildfire management by the Washington State Department of Natural Resources, Bureau of Land Management Plum Creek Timber, Burlington-Northern, and other large landowners.
- C. DEIS, page II-124, Air Quality. It is stated that the Forest will demonstrate reasonable progress in reducing total suspended particulate from a starting point of 49,000 tons from prescribed burning. Please explain what is "reasonable".
- D. DEIS, page III-79. The National Surface Water Survey is being done by the Environmental Protection Agency with Forest Service assistance. Areas known to be sensitive to acid rain deposition should be described and their current and probable future management described. What efforts are being made to coordinate with the Department of Ecology's Air Program in this effort?

II WATER RESOURCES AND INSTREAM VALUES

A General

Monitoring is mentioned several times as the tool that will be used to determine if the Forest is meeting its requirements for protecting its numerous resources. Monitoring can be expensive and requires increased numbers of personnel to do. How does the Forest propose to accomplish the required monitoring and how and in what priority will monies be allocated among the resources?

B Land Management

1. The alternatives contemplate various levels of timber harvest, road building, and other management activities. These activities can have negative impacts on fish habitat (and other instream values) and, therefore, reduce production potential. In light of the varying levels of activities being considered, it seems highly improbable that estimated fish harvest and habitat capabilities would be the same for all alternatives. Please explain this apparent contradiction.
2. A major difference between alternatives C and A appears to be in the acres allocated to wildlife habitat management areas (EW-1). With 100,000+ acres being allocated to alternative C (and harvest levels being higher in C than in A), where will the difference in volume be harvested in alternative C?
3. Why is a zero potential automatically assumed for those watersheds with less than a 30% harvestable area? Other factors need to be taken into consideration, such as location of harvestable acres, location and miles of road, stability of soils, stream channel characteristics, and other factors. Please explain why these factors and others that may be relevant were omitted.
4. DEIS, page III-140. The statement is made, "The exact effect of livestock grazing on fisheries within the Wenatchee National Forest has not been studied." We are glad that this data and information gap has been identified. What is expected to be gained from the studies that are presumably going to be done to fill this gap? How do the studies fit in with maintenance of water quality, grazing allotment plans, and the forest plan?

- 5 DEIS, page III-149, Water - Roads. Other things besides those listed can impact water. These other factors should be discussed. They include harvesting practices (e.g. skidding through and across streams), road abandonment practices, off-road vehicle use, and others.
- 6 Timber cutting patterns can impact snow melt. Smaller clearcuts tend to retain snow longer that larger ones due to shading. The harvest pattern can impact snow melt, and, therefore, runoff. This needs to be discussed.

C. Water Use and Flows

1. The discussion of uses of water originating on the Wenatchee National Forest should mention the importance of those flows for instream resources because of the amount of attention currently being given to fishery-related problems on the mainstem Columbia River.
2. Water use is planned around normal summer low streamflows. Based on the 1985 drought experience, it may be prudent to develop alternative supplies and conservation plans. Please elaborate Forest Service plans relative to alternative supplies and conservation.
3. Considering the present and possible future uses of groundwater in and around the Wenatchee Forest, the description of groundwater resources is lacking. Information concerning sources, problems, anticipated uses, and other, similar, relevant information is needed.
4. Expected impacts of water yield changes on the small streams which are often the most significant streams in terms of fish utilization and production need to be discussed.
5. Projected water needs for various on-Forest and off-Forest uses need to be thoroughly examined.

6. Varying levels of increased water yields have been calculated for each alternative based on timber harvest, but they do not appear to be correlated to anything. What will be the effects on channel stability, sediment loads, and instream uses? In what drainages will these increases have positive impacts and in what drainages will they have negative impacts?
7. DEIS, page II-128, Energy. An explanation of the proposed small hydro-electric sites is warranted.
8. DEIS, page III-78. Since there appears to be a lack of data to adequately quantify cumulative effects, it seems inappropriate to assume that "none known" means no negative cumulative effects exist in a particular drainage.

D. Instream Values

1. One of the Forest's tools for mitigation is to restrict forested openings (opening defined as trees less than 15 feet tall) to less than 40% in any watershed greater than 1000 acres. Has this 40% limit been shown to be adequate? Is it based on research or otherwise documented? Has an analysis been done to show that the Forest can meet their annual cut and still maintain 60% of a watershed with trees greater than 15 feet tall?
2. DEIS, page III-75. There is a brief discussion of impacts from projects on water. This discussion focuses on aquatic and fish habitat. Ecology is concerned with impacts on all instream values, including fish, wildlife, water quality, navigation, recreation, flows, aesthetics, and other environmental values.

E. Fisheries

1. The DEIS shows no substantial differences between alternatives in impacts on instream values, particularly water quality and fisheries. Based on the greatly disparate levels of roading and timber harvesting between alternatives, please provide data and other information to substantiate the apparent lack of difference in impact levels.

- 2 The analysis of the fishery resource states that fish populations will increase with all alternatives
- a Since alternative A is very similar to alternative C, is this statement based on documented rates of increase in fish populations which have resulted from past management? If not, what will make the difference? What data are being used to justify an increase in the fishery in all alternatives regardless of the level of harvest and road building?
- b The increase in the fishery appears to be based on the assumption of receiving K-V and appropriated monies to enhance existing fish habitat to mitigate the effects of timber harvest and road construction. How were the appropriated monies for fisheries calculated for each alternative? Should the Forest expect additional dollars for fish in a time affected so strongly by budget cuts? Should the Forest rely on K-V dollars to mitigate all possible negative impacts to resident fish particularly when "non-essential K-V" is not protected in base rates? Has work accomplished by the use of K-V funds been documented to mitigate all impacts for which it was used in the past?
3. The DEIS is unclear why Alternative G would produce the least amount of cutthroat
- 4 The Forest's riparian protection zone prescriptions appear to offer no protection for class IV streams, yet these streams are numerous, directly affected by timber harvest and provide supportive habitat to downstream channels. How will these streams be managed?
- 5 The DEIS states in several sections that very little data exists to evaluate forest stream habitat and fish populations. How were the effects and environmental consequences to fisheries calculated without sufficient data? How will data which is collected in the future be integrated into the plan?
- 6 DEIS, Page II-78, Table II-1 under Section 7, Wildlife and Fish, in the issue of "Ability to meet fish Habitat Needs," it is stated that various measures, " . . . should assure that no degradation of forest streams should occur " Please elaborate

- 7 DEIS, Page II-78, Ability to Meet Fish Habitat Needs. The strongest words used with regard to meeting fishing demands are, "Should meet the existing demand level " This sounds precarious, what are the Plans if the existing demand level is not met? Page II-2 of the Plan states, "Although Recreation use is projected to increase steadily in the future, the Forest has so much to offer that crowding and shortages are expected to be only localized problems." On the one hand, recreation is projected to steadily increase, but on the other hand fishing demand is expected to (i e, should) meet *existing* demand for first two decades of the plan Demand is increasing, but will only be met at existing level. What will be done about the excess demand? The alternatives do not all extend to the fifty year planning horizon that the plan covers

III WATER QUALITY

A General

A fairly substantial amount of data and information dealing with water quality and its protection is presented in the DEIS and in the Plan. However, the following issues should also be discussed

- Existing water quality
- Current water quality trends
- Water quality monitoring plans
- How water quality monitoring plans will be incorporated into management decisions and programs
- An explanation of how water quality standards will be met
- Whether or not special conditions will be implemented where warranted

Specific comments on various sections of the documents follow

- 1 In several places in both the Plan and the DEIS, the Forest's best management practices are referenced. These should be summarized and included in the final EIS along with a timetable for implementation.
- 2 All alternatives were calculated to show an increase in fish populations regardless of the levels of road building and timber harvest. These increases were based on mitigation and enhancement projects which will depend on funding which may or may not be available in future years.
- 3 Impacts to lakes and ponds from forest practices and mining activities are not addressed. Impacts to groundwater quality are not adequately addressed and could result from the use of fertilizers, pesticides, or herbicides.
- 4 Plan, page II-76. The wildlife and fish comparisons only talk about wildlife. Impacts to fish need to be listed.

5 Plan, page V-20. The water quality monitoring plan does not have enough detail to evaluate it. The reference is made in the table to "see water quality monitoring plan for parameters", but the plan is not included in any of the documents. Six samples per year to evaluate cumulative effects does not seem adequate based on the information presented. A discussion of where, when, and what the sample would cover is warranted. Impacts to both mainstem rivers and small watershed should be studied.

6 DEIS, page III-75. The comments and table III-32 on water quality data need to be explained. The mean value for fecal coliform of 31.99 is depicted with maximum values reaching 2400. Washington State Water Quality Standards for Class AA waters require that fecal coliform organisms shall not exceed a geometric mean value of 50 organisms/100mL, with not more than 10 percent of the samples exceeding 100 organisms/100mL. The table inaccurately shows 50 as being the maximum when it is really the maximum geometric mean value. The water quality data need to be displayed to see the true number of samples exceeding the standard (the table shows a maximum value of 2400) and to evaluate trends indicated by the data. The same may be true for turbidity where maximum values reach 990 NTU's with 5 NTU's over background as a standard. What is the background value for NTU's? A basis for comparison is needed.

7 DEIS, page III-78, Cumulative Effects. How does the Forest Service take into account effects on water quality from other land managers? NEPA requires this to be done (see NEPA, 1508.7).

8. DEIS, page III-78. The statement is made that water quality impacts from mine tailings do not exceed "thresholds" for toxic materials and heavy metals under "normal" conditions. "Thresholds" and "normal" need to be defined. Water quality standards (Chapter 173-201 WAC) apply to man-caused activities under any runoff condition.

9. DEIS, page III-80, Soils. Maps depicting locations of special concern soils areas (i.e., mass wasting areas, degraded areas) would be helpful in comparing past management with current and proposed conditions.

- 10 DEIS, page IV-97. The table of Riparian-Aquatic Protection zone widths gives no indication of what will be left in these zones. Clearing is limited to 40% in a watershed and prescribed burning is allowed, but no indication of leave trees for large organic debris recruitment, temperature control, species composition or other similar, relevant information is given. Requirements for leave trees and understory vegetation should appear in the FEIS. Management prescription EW-2 (page IV-127) does mention extended shelterwood harvest as the predominant method, but this should be clarified. This section further mentions increasing sunlight to benefit stream productivity. What stream productivity parameters will be increased (e.g. what species will be considered?) Resident cutthroat may benefit from higher temperatures, but summer steelhead and chinook could suffer.
- 11 DEIS, page IV-87. The statement is made that any water body found to not meet water quality standards "should" be restored to the prescribed quality (#68). The FEIS should explain how the water body will be restored and replace the "should" with shall.
- 12 Appendices, page B-173. Benefits to fish and wildlife were not included in the present net value computations and need to be accurately compared to the alternatives. The table on this page shows discounted costs and benefits for wildlife and fish, but these remain deceptively constant throughout the alternatives. Please explain why, with the greatly varying levels of impacts to these resources with the various alternatives, the PNV changes so little.

B. Sediment

- i DEIS, table S-2, page S-8, Summary of Results Relating to Planning Problems, the sediment increase index shows increases in all alternatives. Please explain why the planning premise is not the reduction/elimination of water quality degradation. It seems that with better technology and management techniques that land managers would be able to reduce sedimentation.

- 2 DEIS, page II-13. Anadromous fish "habitat" is depicted as rising dramatically in the fifth decade of the Plan. Given that sediment yields rise at about the same time (page II-16), the word habitat seems a misnomer. Fish production may rise in spite of habitat loss due to sedimentation. (See comment on Plan, page IV-61.)
- 3 DEIS, page II-74. The comparisons of alternatives for impacts on water quality should list expected sediment yields. Implementing the same measures for all alternatives to deal with sedimentation does not make sense.
4. DEIS, table II-3a, pages II-114, 115. Water. Improved watershed acreage increases from 57,000 acres to 136,000 acres under all alternatives, but background sediment yields continue throughout the life of the plan at 930.5 thousand tons per year. The correlation between "improved" watershed conditions and a constant sediment load needs to be clarified. Each part of the table is not labeled and this makes locating some items difficult.
5. DEIS, page III-75. The statement is made, "Continued efforts to reduce sediment levels leaving the National Forest are necessary to maintain existing water quality levels." Contrary to this, on page IV-73, Figures IV-31 through 33 all depict increased sediment. It is not clear that whatever the "continued efforts" are can lead to maintenance of existing water quality levels based on the information presented.
6. DEIS, page III-96. Chronic sediment sources not only need to be corrected, but correction should be assured. Identification of problem areas, planning of appropriate remedial actions, prioritization and follow-up all could be part of dealing with these chronic sediment sources.
7. Plan, page IV-61. The plan "delays" the amount of delivered sediment until after the fifth decade when it rises dramatically for all alternatives. In alternative H this is as high as 19.6% over background. This demands an explanation. Most roads will be built within the next 22 years and they are typically the source of much of the sediment. What is the source of the sediment in the latter decades of the Plan?

The preferred alternative has a nearly five percent increase in sedimentation over natural levels for the first five decades, yet it is stated that the Class AA water quality standards will be met. The anti-degradation policy of Washington state [Chapter 173-201-035(8) WAC] provides that beneficial uses shall be protected allowing NO water quality degradation which would interfere with existing beneficial uses.

- 8 Appendices, page B-184 The expected sediment increases do not appear to meet the anti-degradation clause of the water quality standard (see comment number seven, above). The expected commercial harvest of anadromous fish in the year 2030 as listed on this page shows significant differences alternative E provides 743,000 pounds with alternatives A, G, F, G, H, and I all only providing 482,000 pounds -- a 65% reduction. Obviously, impacts from the Forest's management activities become the limiting factor for fish production with this dramatic degradation of this beneficial use. Note that this also will be well after the solving of management problems downstream from the Forest on the Yakima and mainstem Columbia Rivers, so that those factors currently affecting production cannot be blamed for these reductions.

C Mines

- Under mining activities, only past mining is discussed with no discussion of future activities such as road building and site disturbance for exploration or extraction. Even though these topics may be covered in separate, project-specific environmental documents, some generic impacts should be covered.
- DEIS, page III-78, Cumulative Effects Potential water quality degradation due to leached heavy metals and other toxic substances associated with mine tailings are discussed. It is stated that water quality standards would not be exceeded under normal runoff. Abnormal runoff conditions and the prescribed management reaction to these needs to be discussed. A definition of normal needs to be provided. What is the management prescription for these tailings?

- DEIS, page III-149, Water - Minerals Peshashtin Creek has been recommended for additional sampling or elimination from the Washington State list of potential hazardous waste sites. Which action is going to happen and based on what criteria?

D Roads

- Roads contribute much sediment to streams. Abandonment of unneeded roads, both existing and future, needs to be considered and would need to include measures to preclude future erosion, mass wasting, and sedimentation problems.
- Any new or reconstructed bridges must be located so existing water quality is not altered. Any non-emergency alteration of water quality requires a short-term water quality modification from the Department of Ecology.

E Range

- Why do all alternatives show an increase in grazing? From the information provided it is not clear that the demand is there for increased grazing.
- DEIS, page III-47, Water degradation is identified as a problem associated with rangeland management. While it is good to identify that a problem exists, one needs to go farther and discuss the degree of the problem, possible solutions, a timeframe to develop and implement a plan to solve the problems, and, lastly, follow-up and adjustment to determine how well the effort worked and what could and should have been done differently to achieve better results.
- DEIS, Page II-84, Range Management The preferred alternative ultimately provides for an increase of between 10 and 15 thousand AUM's over the five decades of the plan. In the section on water quality (page II-74), measures implemented to maintain or enhance water quality are the same for all alternatives. This approximately 10% rise in the number of AUM's may have negative impacts on water quality. Please explain how the 10-15 thousand AUM's will be accommodated and the resource impacts associated with it (e.g., wildlife, water, aesthetics).

- 4 DEIS, page IV-126 Management prescription EW-2 (Riparian-Aquatic Zone) allows grazing and will feature an "extensive scheme" for management. What is the "scheme"? On the same page it is stated that allotment plans will maintain or "enhance" the riparian-aquatic zone. We are interested in how this will happen since it is our experience that livestock do not enhance riparian zones, any "enhancement" is usually incidental to much damage.

IV WASTE MANAGEMENT

The documents should address the types, amounts, and the methods for handling and disposal of wastes generated by recreationists (dispersed, campground, special events, and other), at work sites, work centers, and ranger stations. A litter control plan, discussing problems, solutions, and future opportunities would be beneficial.

The documents do not contain any information regarding recycling. Does the Wenatchee National Forest have a recycling plan? Considering the amount of public concern and the need for conservation of natural resources, if there is no recycling plan, one needs to be developed and should include such things as recycling of office paper, recycling of motor oils from vehicles, and the reuse of materials where feasible. The Litter Control and Recycling section of the Department of Ecology's Yakima Office ([509]575-2800) can provide advice and guidance in developing litter control and recycling plans.

We are concerned that former Forest Service dump sites (and also sites of unauthorized dumping) may contain potentially dangerous materials, such as empty herbicide containers. There needs to be an identification and evaluation of these former dump sites to determine if there are any problems, such as leaching, of hazardous or other materials from these sites.

Mines and mine spoils are mentioned several times in the documents. Oftentimes there are chemicals and other substances [e.g. fuels] associated with mining that could cause environmental damage. Mine spoils may contain heavy metals. These potential sources of hazardous materials need to be identified and evaluated. If the evaluation determines there are solid or dangerous wastes present at these mining sites (or any other sites), disposal shall be in compliance with Chapter 173-303 and 304 (WAC), the laws for State Dangerous Waste and the Minimum Functional Standards for Handling Solid Waste, respectively.

Many Forest Service installations and work sites have storage areas for hazardous materials, such as fuels or herbicides. Spill containment procedures, equipment, and personnel need to be discussed. Some installations may have underground fuel storage tanks that are extremely old and may have high risk of leaks. Identification and evaluation of "high risk" underground storage tanks is needed, especially those with the potential to contaminate soil or groundwater, particularly groundwater used for water supplies.

V GENERAL and ENVIRONMENTAL QUALITY

A General

- 1 An index would be helpful in finding specific data and information that may be located throughout the documents. A cross-reference guide would aid in evaluating the data and information.
- 2 Instead of viewing some circumstances and activities as "irreversible", it may be more appropriate to view them as an opportunity to do something different.
- 3 Page numbers are occasionally wrong. For example, in the Appendices Table of Contents for Section B, Chapter VIII is listed as starting on page B-155 when it actually starts on B-157.
- 4 Two documents that can have an impact on resources within Wenatchee National Forest are

Beery, Marsha 1982

Wenatchee River Basin Instream Resources Protection Program Including Proposed Administrative Rules (WAC 173-545) and Supplemental Environmental Impact Statement (Water Resources Inventory Area 45) Washington State Department of Ecology.

USDI Bureau of Reclamation and the Washington State Department of Ecology January, 1986.

Plan Formulation Summary (Yakima River Basin Water Enhancement Project, Washington) Report to Regional Director, Bureau of Reclamation and Director, Department of Ecology

Copies of these documents can be obtained by ordering through the Publications Officer, Department of Ecology, Mail Stop PV-11; Olympia, WA 98504-8711

- 5 The impacts of illegal and unpermitted uses of the Forests need to be examined and their impacts analyzed and worked into the planning process. Activities that should be examined include.

-Failures to abide by timber sale contract provisions (for items like yarding through streams, draining petroleum products onto the ground, cutting leave trees in the riparian zone)

-Grazing allotment problems (putting animals on too soon or taking them off too late, management around water courses, spreading of noxious weeds)

-Poor roading practices (logs buried in roadbeds, poor culvert placement)

-Special uses (poor access road management by permittees, poor mine management)

B Management and Public Involvement

- 1 A portion of the RPA targets are allocated to each Region and then to the Forests, and finally down to Ranger Districts. The criteria that are used to allocate a Region's/Forest's/District's part of the overall RPA target needs to be discussed. While the criteria are discussed in the Regional Guide, there needs to be at least a brief discussion of the allocation process needs to be included in the DEIS.
- 2 The Multiple Use-Sustained Yield Act of 1960 says nothing about community stability but refers to recreation, range, timber, watershed, wildlife and fish as the multiple uses.
3. DEIS, page II-134, Social Effects. The basis of how, when, where and to what extent attitudes, beliefs and values would be impacted needs to be explained. From the information presented in the table, there is no way to see how the inherent conclusions were derived.
- 4 Budget increases are unlikely under Gramm-Rudman. Budget cuts are generally the rule. How would budget cuts be distributed among the resource areas?

- 5 What are the differences in management costs between alternatives?
6. How will comments on the DEIS be addressed in the final? Will there be an opportunity to see what comments others are making and whether the Forest Service response is adequate?
7. DEIS, page II-3. The costs of the alternatives need to be discussed and displayed. Virtually anything can be done, but the costs need to be shown. For example, it is technologically possible to remove all sediment from a stream downstream from a sloughed-out trail, but the costs incurred to do that would not be commensurate with the benefits.
- 8 It would be beneficial in the evaluation of alternatives, if impacts on the lands' productivity were displayed across a variety of resources (i.e. timber, forage, water, wildlife, fish, and recreation).
- 9 DEIS, page II-148, Nonpriced Outputs. It is stated that subjective judgements are made in assessing whether benefits from the nonpriced outputs outweigh the opportunity costs of priced outputs. While we have no suggestions for a better way to do this comparison, we would like to see the criteria and other factors that went into the judgement, including a definition of the "check-off point" as to when a nonpriced output is "more valuable" than a priced output.

C. FORPLAN Model

- 1 Mathematical Model (FORPLAN)
A description is given of what FORPLAN is supposed to do, taking into account costs, budgets, resource limitations, and the like. A major problem with modeling, as evidenced in the FORPLAN description, is that it cannot model values. It cannot compare, in an acceptable fashion, commodity values and non-commodity values. It is reasonable to compare commodity values with other commodity values [such as different harvest timings], but *not* with non-quantifiable values.
- 2 In the FORPLAN model, how many stems (or acres) does one plot represent? Is the sampling frequency per acre large enough to yield reliable results for all resources?

- 3 FORPLAN only models *monetary* (i.e., quantifiable) cost and benefits. How are non-monetary costs and benefits analyzed, evaluated, predicted, and monitored?
- 4 The objectives and constraints for the FORPLAN model need to be displayed. The process for developing the objectives should be visible.

D Cumulative Effects

- 1 While it is true that the Wenatchee National Forest is not responsible for off-Forest uses of water, the cumulative and synergistic impacts of forest activities with non-Forest activities need to be examined.
2. The cumulative effects of the Forest Plans on the following areas must be defined and evaluated
- a Tourism. The impacts of reducing visitor days on one Forest may be small but state-wide, and coupled with Oregon and Idaho, they can be significant.
 - b Timber harvest levels and rate/timing of harvest. These factors can impact the local, regional and state economies and, to some extent, demographics.
 - c Habitat manipulations that reduce wildlife habitat, especially critical areas such as riparian zones, calving areas, migration routes, and wintering areas need to be discussed. How and when habitat manipulations of adjacent Forests and adjacent land managers are done can impact wildlife resources.
3. The cumulative effects analyses are very general, non-quantitative for most resources and based on incomplete data. Cumulative effects were calculated for water and soils and expressed as water yields and sediment, but these two parameters were not correlated to any beneficial uses.

- 4 DEIS, page III-76 The discussions concerning cumulative impacts fail to meet National Environmental Policy Act (NEPA) requirements. In NEPA, section 1508 7, Cumulative impact; cumulative impact is defined as the impact on the environment which results from the incremental impact of actions when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-federal) or person undertakes such other actions. The following topics, their contribution and how they combine to cumulatively impact resources need to be discussed, as a minimum

- Intermingled ownerships and related land management activities
- Water use
- Mining

Cumulative effects in all major functional categories should be examined, including timber, water, wildlife, range, recreation, soils, cultural resources, and special uses. In the section of NEPA on Scope (1508 25), connected actions are to be discussed in the same project statement

E Vegetation

- 1 Page S-14, Vegetation. The Environmental Consequences of the Alternatives on vegetation primarily considers trees and forage. Species other than tree and forage species need to be thoroughly examined and discussed for such things such as how they fit into the various forest ecosystems, what happens under various management scenarios, and how the Wenatchee Forest intends to manage non-tree and non-forage species. This "non-commodity" vegetation could be handled in much the same way as non-game species of wildlife.
- 2 How is the removal of the timber and the removal of forage by grazing affecting ecosystem balance and nutrient cycling? What is the management program for replacing nutrients lost due to soil erosion, removal of timber, removal of mined materials, and removal of forage? How is the bioregional energy balance affected?

F. Range

- 1 DEIS, page III-148, Priced Outputs. The values received for AUM's are not based on market transactions, but are based on grazing permit fees. This is not the best way to evaluate value received. Like the other products mentioned in this section, grazing value should be based on market transactions. This would allow comparisons with other resources and help decisionmakers better decide the efficiency of spending -- i.e., are they putting the money where the return is the greatest? Further, by only ranking the value based on fees received, the value is underestimated. Why is the "value" for grazing determined in this way rather than like the other resources? All costs and benefits associated with cash resources need to be considered when evaluating value.
- 2 Plan, page IV-53, Vegetation. Several references are made to the need for range analysis work and evaluations in order to develop allotment plans. These plans should be based on the biological and physical capabilities of the allotment and then meshed, as nearly as feasible, with overall management goals. The statement, "through full implementation of these reanalyzed plans that livestock numbers will be increased.." presupposes the outcome of the data analysis. Range analyses may or may not show the allotments capable of sustaining additional AUM's without damage to other resources. How is the Forest making the decision to increase grazing in the face of data that admittedly has not been collected, let alone analyzed?
- 3 Plan, page IV-53, Vegetation. In the first paragraph it is stated that the expected increase in permitted use will be accommodated through the second decade. As was done for other resources, livestock use through the life of the plan needs to be considered.
- 4 Overgrazing may result in selecting for an undesirable plant species and that species may not be usable by either wildlife or livestock.

G Wilderness

- 1 DEIS, Alternatives Considered. The document need to contain a full range of alternatives. Not considering the addition of new areas to the Wilderness system unnecessarily limits the range of alternatives. The rationale for the elimination from study of some of the alternatives needs to be displayed.
- 2 Impacts of management activities adjacent to (but outside of) a Wilderness on the Wilderness need to be examined and discussed. Subjects to be discussed should include at least the following noise impacts on wilderness values, gas and oil drilling under Wilderness, and air quality and visual impacts from prescribed burning.
- 3 The amount of wilderness and wilderness use is depicted as the same for each alternative in table S-2 on page S-9 of the DEIS. By not even contemplating additional Wilderness, the Forest is unnecessarily omitting alternatives. There needs to be a demonstration of why an alternative that would include the adding of more wilderness to the Wilderness Preservation System was not included. Further, table II-3b that begins on page II-124 of the DEIS and is titled, "Qualitative Resource Outputs and Environmental Effects," does not mention wilderness. Some of the prime values that wilderness provides are qualitative and they ought not be omitted from the table.
4. Page S-16, Section K, Irreversible or Irrecoverable Commitment of Resources. The statement is made that timber resources can be irretrievably lost by land being designated as Wilderness. The President can recommend declassification to Congress, which can then, in turn, act upon that recommendation. Admittedly the likelihood of this scenario is small, but it is possible.
5. DEIS, page II-91, Management Areas. Conspicuous due to their absence are Spotted Owl Management Area Plans.

- 6 DEIS, page III-16, Inventoried Roadless Areas. While the Washington State Wilderness Act of 1984 did not require a review of remaining roadless areas or require that remaining roadless areas be managed to preserve future wilderness designation options, neither did it preclude the Secretary of Agriculture from preserving the option. The statute says the roadless areas "need not be managed," which means they can be managed to preserve wilderness values.
- 7 DEIS, page III-33, Wilderness Capacity and Demand. A map(s) that would show the relationships between the various Wilderness areas and the subdivisions within them would be beneficial in assessing needs, cumulative effects, and impacts to other resources.
- 8 Forest Service management policies for backcountry and Wilderness areas can have serious impacts to resources. Management of sensitive areas around water bodies is especially important. Limiting party size and composition can have beneficial impacts. For example, limiting the number of horses in a party can reduce water quality degradation by reducing fecal coliform, reducing soil compaction (and thereby increasing runoff), reducing the number of trees with horse-caused injuries, and the unpleasantness of manure in trails which may eventually be washed into water. It appears that the current policy of a combination of people and horses adding up to twelve is working and with District Rangers having the prerogative of allowing additional people or animals, any change to allow increased numbers across the board would not be warranted.

H Timber Management

- 1 What is the percent error in the timber harvest calculations and what will be the likely impacts on local economics? Many things are based on the assumptions in the timber harvest calculations. If the confidence level of the timber harvest calculations is low, it may invalidate some of the proposed actions that are based on the assumptions.
- 2 DEIS, pages II-111, 112 Timber. It would be helpful to have the timber sale quantities in acreages (as well as volume); in order to make comparisons with acreage reforested and subjected to timber stand improvement work.

- 3 DEIS, page II-112, Under natural reforestation It is assumed the correct acreage under Alternative C is 22 thousand acres rather than 22,000 acres, as written
- 4 The mean annual increment for various forest types would give a gross characterization of overall impacts of timber harvest activities on timber availability, cutting rates, and compliance with the Multiple Use - Sustained Yield Act of 1960

negative impact on environmental quality than do trails through such things as water quality degradation (during construction and maintenance), displacement of animals through the removal of habitat, acreage made unavailable for other uses, management problems (e.g. litter, vandalism, illegal firewood removal, poaching), maintenance costs, and aesthetic impacts

The Wenatchee needs to examine what other trail managers in the area are doing. There are no other significant trail systems in the Wenatchee area that are not managed by the Forest Service. Therefore, the impacts of Forest Service trail management decisions may put undue pressure on those few miles of trail outside Forest Service jurisdiction.

I Recreation and Wildlife

- 1 DEIS, page S-11, section 1 Recreation It is stated the amount of unroaded recreation outside wilderness is a major concern on the Forest. What is to preclude the changing of an administrative classification status from unroaded to roaded and what would be the ramifications?
- 2 DEIS, page III-37, Wildlife Only vertebrate species are acknowledged to exist on the forest. Other species, such as insects, can have a significant impact on forest resources and can be impacted. Food chain impacts need to be addressed. If there are no data available, the data gap needs to be identified and information gathered.
- 3 DEIS, page III-137 The statement, "There are no significant interactions between air and wildlife" is erroneous. Animals breathe, birds fly.
- 4 DEIS, page III-142, Threatened, Endangered and Sensitive species. There is no mention of species listed by the Washington Department of Game.
- 5 With the current and projected levels of recreational use in unroaded areas, it is not clear that increasing roading while reducing the numbers of miles of trails is a good approach to meeting this demand. There needs to be a justification for removing 51 miles of trail during a time when the demand for trails is increasing. Nationwide, including the Pacific Northwest, trails are being reduced in numbers and reducing the number of miles of trails on the Wenatchee National Forest would only exacerbate that situation. The opportunity to develop or maintain trails in a forested setting such as the Wenatchee are diminishing. Roads have a much more

Specific examples of these conflicts involve fish, big game, old growth indicator species and wildlife economics. It appears that model outputs of fish are not affected by differential sediment volumes, a result that seems counterintuitive. Especially since you state that some streams may suffer cumulative impacts, we would expect sediment outputs to be unevenly distributed, reaching impacting levels in some locations. We believe that management activities would affect fish habitats and populations. Although activities off WNF may have the largest influence on fish production, it is still important that on-forest actions aid recovery efforts. We suggest that the WNF examine fish/sediment models developed on other forests

With big game, we feel that differences in Forest-wide harvest activity and road management would far outweigh the effects of 1300 acre-equivalents per year of habitat improvements. In addition, it appears that what we see as limiting factors for the various herds are not incorporated as model parameters. Projected population increases within the Plan may be possible, but we believe that they would require a concentrated program of winter range improvements and strict vehicle access restrictions. Our suggestions for big game management emphasis areas are discussed below.

With old growth indicator species, such as pileated and three-toed woodpecker and marten, it appears that minimum management requirements (MMR's) would not be met. Information on dispersion distances (EIS, page III-43) conflicts with table outputs given earlier (EIS, page II-108). In addition, we believe that management should be above MMR level for all species. Also, the amount of acreage allocated to SOMAs is less than 25% of the average old growth found in Washington spotted owl home ranges.

We also believe that the alternatives would vary in their effects on recreation, and that the local economy would reflect these differences. Fish and wildlife oriented recreation supports a significant amount of economic activity statewide, totaling \$864 million in 1983, \$2.8 billion counting the effects of a standard spending multiplier. We know that campground occupancy rates can fluctuate with the level of opportunity for fishing and hunting. In addition, you have stated that recreation contributes more to local economy than timber. It seems reasonable that differences among alternatives should lead to different effects on the local economy's recreation sector. Perhaps our disagreement stems from your assumed linear relationship between road mileage and total recreation. It would be helpful to describe model assumptions and parameters so that these differences might be resolved.

Three other process-related issues should be raised. First, we suggest that the Plan would benefit from a broader range of livestock grazing alternatives. The approaches there appear very similar, especially given a certain existing level of conflict. Resolution of current and possible future problems is very important to us. Second, we strongly recommend that you strengthen the language in your wildlife oriented Forest-wide Standards and Guidelines. We do not believe that qualifiers such as "if possible", and "strive for" are

PROPOSED LAND AND RESOURCE MANAGEMENT PLAN
AND DRAFT ENVIRONMENTAL IMPACT STATEMENT
Wenatchee National Forest

Dear Mr. Torrence:

Washington Department of Game staff have reviewed the Proposed Plan and DEIS, comments follow.

We wish to thank you for the opportunity to respond to your Plan documents, and for Wenatchee National Forest (WNF) efforts to include us at each preliminary step. Land and waters in WNF are extremely valuable for the fish and wildlife resources managed by this agency, so coordination with the Forest is a high priority for us. We appreciate how immense a task it is to put together a comprehensive resource plan which features a full range of alternatives, you are to be commended. It is our intention to continue to work with WNF to achieve successful wildlife management on the Forest, meeting population goals, and making wildlife oriented recreation available to the public

Because we believe that impacts on fish and wildlife would be higher than stated, we cannot support your preferred alternative as formulated. We do hope that the level of detail we provide will be helpful in arriving at a final plan which is better for wildlife and still meets other resource requirements. Our response focuses on the changes that we believe should be made. We do not dwell on the good parts of the documents, although much is well done. Brief examples are the formulation of most Forest goals, and from the standpoint of informing effectively, most of the tabular displays and diagrams. Please understand that we recognize many others, though they may not be mentioned

A major source of concern involves mechanics of the planning process. Model outputs do not always match what we would expect to occur over the various alternatives. Because the assumptions and parameters you use in model runs are not shown, there is no chance of reconciling these differences. Moreover, we are unable to add our expertise to refine the models. We strongly recommend that you include model descriptions in the appendix volume, as well as output tables for all indicator species across the full planning horizon.

K-323

Page 3

appropriate for this section. Instead, it would be helpful to set firm standards, as was done for other resources, to implement Forest goals, and to state operative minimum management requirements for all indicator species. The third issue involves fish and wildlife valuation.

Economic Value of Fish and Wildlife

We are concerned that your economic efficiency calculations seriously underestimate the value of fish and wildlife. These are public resources, enhancements represent real benefits and impacts produce real losses. Both affect present net value. Where the resource is enhanced, benefit is measured by the public's net willingness to pay (WTP) for extra outputs. When losses occur, the proper measure is net willingness to accept payment (WTA) to do without the resource.

We believe there are several ways that PNV figures are biased away from fish and wildlife values. First, an arbitrary reduction of 37.5% was made from the numbers derived by Loomis and Sorg for the 1985 RPA documents. We strongly believe the justification for that reduction, which you give in the Appendices, page B-81, is not correct. With Travel Cost Method (TCM), an implicit demand curve is mathematically derived, and consumer surplus determined. Net, not total, willingness to pay is measured by consumer surplus. We agree that TCM studies are site-specific. However, the conjecture that study locations are typically high quality sites should be substantiated and quantified by sensitivity analysis before value reductions take place.

In fact, there is more reason to believe that the Loomis and Sorg data underestimated applicable wildlife values. TCM measures only the use component. Other sources of value involve existence of the resource, option to make future use of it, and opportunity for increased knowledge to lead to new or enhanced uses. For some species and ecosystems, we would expect these components to add significant value.

Another factor is that no attempt is made to incorporate fish and wildlife losses as costs in PNV calculations. It should be noted that WTA is the proper measure of value for this purpose, and that WTA magnitudes are typically higher than those of WTP. In addition, losses should be measured from current conditions, not current direction.

Finally, a small relative bias is introduced through attributing a 1% real growth rate in timber prices, while holding other resource values constant over time. Taking into account the relative growth of demand for fish and wildlife oriented recreation over the last 10-20 years, we feel that timber values are unjustly favored by your assumption.

Recommended Alterations to the Preferred Alternative

The recommendations which follow include changes in prescription definitions, specific allocations, and management techniques. We believe that their adoption not only would be better for fish and wildlife, but also would produce a stronger plan. We ask you to make these changes to your preferred alternative. Major topics are grouped under separate headings.

Management Prescription EW-1

We believe that several refinements need to be made in this management area to assure successful big game habitat emphasis. As a start, it would be very helpful to strengthen the associated language in your Forest-wide Standards and Guidelines (Plan, page IV-91). However, the primary shortcoming is that a general prescription is written to cover multiple species and seasons. To remedy this, we recommend that you develop separate sections for deer, elk and mountain goats, with appropriate management criteria for each, as well as for winter, summer and transition range. As an example, objectives for winter range could include protection and development of thermal cover, and protection of forage from overgrazing. Summer range objectives could include creation of forage areas, road closure targets, and protection of calving, fawning and hiding areas. Specific target criteria would vary by species.

In addition, we recommend that all activities within the EW-1 management area be judged by their impact on big game. Optimum cover/forage ratios are discussed but not often specified in your documents. For deer and elk winter range, 40-60 should be the target, with specific canopy closure, as identified in Thomas, et al., *The Blue Mountain Handbook*, for cover areas. Increased habitat effectiveness should be achieved. In this regard, on low elevation winter range, we believe that reduced timber harvest, and road and ORV trail closures during key periods will be necessary.

Your preferred alternative incorporates most of the big game acreage we specified at an earlier stage in the planning process. We ask that you add the rest of that acreage (to match the Alternative G allocation), as well as the following area.

- 1 Mud Creek corridor, Entiat drainage (change from ST-2, RM-1)
Extensive use by mule deer in winter and during fall migration

Management Prescription EW-2

Riparian zones make up a small portion of Wenatchee National Forest, but support a larger number of species than any other management area. Because of this abundance, we support the prescription goal of optimizing habitat for wildlife. However, we do not agree that your proposed management will attain

James F. Torrence
September 22, 1986
Page 5

00582

the optimization you seek. Your proposed prescription retains less than one-third of the big trees, we suggest that canopy cover should exceed 60% to be more optional for wildlife.

We recommend that area definition be functional. Minimum zone width should be based on the area of physical influence measured by slope distance equal to natural tree height. Soils, vegetation and topography can then be used to widen the zone, where appropriate. In addition, reaches of class III streams should be included in this management area when key wildlife habitat is present. Harvest within the riparian corridor should emphasize maintaining cover, stabilizing soils, and providing large organic debris for instream habitat needs. Large snags must be present for the many species that use them. Instead of shelterwood, selective harvest of intermediate-sized trees would be better for wildlife. Maximum harvest per decade should be 5%. Snags should be maintained at 100% potential woodpecker habitat.

Management Prescription OG-1

We believe that protection of old growth habitat should be given very high priority. At the same time, we question whether old growth attributes can be adequately recreated by management activities. For this reason, we strongly recommend that existing old growth areas be dedicated, without allowable harvest. Acreage scheduled for addition, due to future growth, to the OG-1 management area under your preferred alternative can be used as study sites, to judge the effectiveness of actions taken to recreate old growth values. Until the success of these management activities is assured, we consider it extremely unwise to allow further loss of this dwindling resource. The existing old growth prescription will not meet the cover needs of your indicator species. We suggest you reference materials used to develop MMRs and C. Phillips, et al., Siuslaw National Forest.

Roads

Of all forest management tools, roads are the most impacting. Each mile of road requires the destruction of four acres of wildlife habitat. Roads allow human intrusion, which leads to increased harassment, poaching and vehicle/animal accidents. Many species of wildlife, but particularly big game, avoid roads, effective habitat and carrying capacity are reduced. Populations are lowered, as are high quality viewing and hunting opportunities. In addition, roads are the greatest source of increased sedimentation of forest streams, which can significantly impact fish populations.

To mitigate these adverse effects on Wenatchee National Forest, we strongly recommend that the following measures be adopted as standards. It is important that new roads avoid key habitats, including riparian zones, wetlands, natural forest openings, and places with special uses, such as deer and elk travel corridors and calving areas. Buffers of natural vegetation should be left to

James F. Torrence
September 22, 1986
Page 6

screen these critical habitat features. When stream crossing is necessary, it should be done at a right angle, to minimize the area of impact. It is also important to limit open road densities to levels compatible with prevailing wildlife use. Optimum elk habitat requires 0.2 mi/sq mi or less, significant drops in habitat effectiveness for deer and elk occur at levels above 1 mi/sq mi. We ask you to strive for optimum level in the most critical areas, which we would be happy to help you specify. Elsewhere on WNF, our goal for maximum open road density is 1 mi/sq mi.

On WNF, average road density is listed at 3.75 mi/sq mi in roaded areas. We understand that this figure does not take into account spurs and dead-end roads. Even at the lower number, habitat effectiveness for deer and elk is reduced by about 50%. We note also that road mileage would increase under every alternative. To mitigate adverse effects, we recommend that you minimize new road mileage, and develop closure programs on both new and existing roads to approach less impacting density levels. Regrading and revegetating corridors is most effective. Road management programs, either with gates or the green-dot system, can also be used. Often, seasonal closures are sufficient. Washington Department of Game priorities for new road management areas on the Forest are as follows:

1. Entiat, Mad and Chiwawa River drainages - Entiat Ranger Districts
2. State Rte. 2 to Alpine Lakes Wilderness - Lake Wenatchee R.D.
3. Wenatchee Mountains, east of U.S. 97 - Leavenworth and Cle Elum Ranger Districts
4. South of Interstate 90 near Cle Elum - Cle Elum R.D.
5. Thorp Mountain area - Cle Elum R.D.
6. Nile River drainage - Naches R.D.
7. Tieton River drainage - Naches R.D.

As for specific construction projects, we recommend that you not permit development of the Naches Pass Road. The Little Naches basin is critical summer and transition range for big game. It is also a major migration route for deer and elk wintering in the Naches, Wenas and southwest Kittitas County valleys. Motorized traffic in the drainage is already at high levels, adversely affecting these species. Putting in the road would compound this impact, and would compromise co-operative efforts by our two agencies and Plum Creek Timber Co. to control access.

Page 7

Off Road Vehicles

Our concerns over this issue are long-standing, with correspondence dating back to the first Wenatchee National Forest ORV Plan Environmental Assessment in 1975. Since that time, we have consistently stated that ORV's have a detrimental impact upon wildlife and their habitat. Our position is based upon the large number of professional studies documenting impacts of motor vehicles on wildlife. Many of these studies were conducted by the Forest Service, and published in professional journals. Unfortunately, little work has been undertaken to document impacts from ORV use in forested habitats. We believe that a comprehensive study of these potential adverse effects should be undertaken. At the same time, conflicts have grown. With the availability of funds in 1978 from the Interagency Committee for Outdoor Recreation (IAC), ORV trail development on WNF increased substantially. This occurred despite our request that site-specific wildlife and habitat evaluations be done for each proposed development before project authorization. Our position today remains the same, no new ORV development should occur on WNF until the following have been performed to standards mutually agreeable to WDG and WNF:

1. Complete a comprehensive study that quantifies the extent and timing of wildlife and habitat impacts from ORV development and use.
2. Develop and implement a mitigation plan to offset or minimize any ORV impacts identified in the comprehensive study
3. Develop and implement a monitoring plan of ORV use on WNF trails, consistent with Executive Order 11644 (USDA Forest Service, 1977). The monitoring plan should be designed to identify impacts before they occur, and should allow for successful implementation of the mitigation plan of (2), above. We believe the existing ORV monitoring plan is not comprehensive enough to meet basic needs of wildlife and habitat management
4. Develop and implement effective enforcement and education plans for ORV and road management programs on the Forest. Currently, the onus of enforcement is borne by County ORV Deputies and our Wildlife Enforcement Agents. There are too few personnel to do an adequate job. Because federal land and statutes are involved, we feel that WNF should assume lead responsibility for enforcement of ORV use on the Forest

Finally, we believe that high wildlife habitat values cause some areas to be inappropriate for ORV development and use. We have already identified a number of these sites, and believe the bulk of remaining unroaded areas may well fit into this category. Others will require careful evaluation before a determination can be made. One specific case for which we have recommended no further ORV development is the Negro/Shazer proposal. This agency performed a wildlife assessment for the project. Our recommendation, based on wildlife needs and habitat use of the area, was not to build or improve trails for ORV

K-326

00582

James F. Torrence
September 22, 1986
Page 8

use. We request that these recommendations be adopted. If they are not, please send us notice of the reasons for your decision.

Roadless Areas

Because roads are so impacting, wildlife would benefit by leaving as many roadless areas as possible in a pristine state. We believe that your description of the roadless percentages of inventoried areas after planned entry understates adverse effects. With the proposed management of your preferred alternative, these sections will not be roadless. For clarity, it is also important to separate your treatment of inventoried roadless areas from that of wilderness. The two classifications feature different values, and support different uses.

When entry is unavoidable, low harvest intensity, appropriate to transitional areas, should be applied. Road mileage should be minimized, with all roads closed to public access. After harvest, regrading and revegetation of corridors should be used to the maximum extent possible. In addition, we believe that certain changes should be made in management allocations if inventoried areas must be opened. We repeat that our strong preference is that they not be roaded. The changes are as follows:

1. Entiat, Stormy Mountain and Slide Ridge - EW-1
Key summer range and migration routes for Entiat mule deer herd. We are especially concerned with impacts of new roads on herd ecology and recreational quality.
2. Nason Ridge - RE-3
Important habitat for a major mountain goat herd. To reduce impacts, decision to allow ORV access should be reconsidered.
3. Alpine Lakes Adj. - RE-3
Again, to reduce impacts on mountain goat.
4. Devil's Gulch, Waneum and Lion Rock - EW-1
Important summer range and migration routes for the Colockum elk herd - very high priority for remaining roadless. Proposed allocation would allow improvement of cover/forage ratio. Focus should be on minimizing impact of roading, with low mileage and full closures required. Grouse Spring Road, in Waneum area, should also be closed, at least seasonally
5. Taneum, Manastash and Quartz
Quartz is the last undisturbed area between major summer and winter ranges. We believe it should be left unroaded. ORV trails above Milk Lake should be rerouted to protect meadows and riparian zones. Low mileage and cooperative road management programs should be emphasized in interspersed ownership of Taneum and Manastash areas.

00582

James F. Torrence
September 22, 1986
Page 9

6. Norse Peak Adj.
ST-1 allocation is important mountain goat habitat, and should not be roaded or logged. In other sections, close roads after harvest.
7. William O Douglas Adj.
Change GF to ST-2. Many small fragments provide summer range and migration routes for deer, elk and mountain goat. Roads should be closed after harvest; transitional nature should be emphasized. For specific segments of this area:
 - a. Miner's Ridge - change ST-2 to ST-1
 - b. Clover Springs - change GF to ST-2
 - c. Rattlesnake Cr. - change RE-2B and GF to EW-1
 - d. Timberwolf Mt. - close all new roads, restrict ORV's
 - e. Wildcat Cr /Russell Ridge - change all to RE-3
8. Blue Slide
Change majority of Divide Ridge from GF and ST-2 to ST-1. Allocate U.S. 12 to Teton River Valley, and area near Grey Cr Campground to ST-2. Close all roads after harvest. Key summer range and migration routes.
9. Goat Rocks Adj.
Close all roads after harvest.
10. Thorp Mountain
Change RE-2A to RE-3.
Mountain goat population already impacted by ease of access. Coordinate activities with private landowners.
11. Teanaway
Change SI-1 to RE-3.
Summer range and migration routes for major mule deer herd, with northern portion of area supporting mountain goat.

Range Allocations

Potential conflicts that livestock can create with wildlife use of the Forest include overgrazing, impinging on critical habitats, and passing diseases. To minimize these problems, we suggest that a number of measures be taken. First, grazing allotments should calculate AUMs only on the acreage that is actually used by livestock. Level to moderate slopes and presence of water are necessary.

Second, allotments should avoid critical habitats. In this regard, we recommend that fencing or reduced stocking be used to protect riparian zones, and achieve the goal of optimum wildlife habitat. Specific priority areas for this action are within drainage bottoms on the Manastash Allotment, and in the

K-327

00582

James F. Torrence
September 22, 1986
Page 10

Teton River and Rattlesnake Creek drainages. Timing restrictions should be sufficient to remedy another specific conflict, the competition for space between cattle and elk during calving season on the Table Mountain Allotment. A conflict in the Manson Game Management Unit should be studied to determine the proper course of action. We believe that any new grazing should be directed away from big game winter range.

Finally, domestic sheep should not be allowed to graze near bighorn sheep habitat. Diets overlap, and bighorn have no natural defenses against diseases and parasites that can be passed. Specific areas of conflict on WNF are Clemans Mt. to Bald Mt., and the Swakane/Chumstick Mt. vicinity.

Forest Grouse

We would also like to recommend opportunities to benefit ruffed grouse, as well as the other grouse this indicator species represents. Riparian management as we have suggested above would provide a good base. In addition, we would support reduced logging, grazing and ORV use adjacent to natural meadows. Specific areas of key grouse habitat are as follows:

1. Rocky Saddle - Milk Lake, Naches R.D.
2. Bald Mt. - Rock Cr. - Cattle Camp Spring - Two Point Spring Naches R.D.
3. Bethel Ridge - Microwave Tower Area, Naches R.D.
4. Lion Rock - Table Mt., Cle Elum R.D.
5. Sugar Loaf Mt., Entiat R.D.

Mission Ridge and Other Winter Recreation Facilities

Because of intermingled ownership, 1200 acres of Game Department lands were leased for development of the Mission Ridge Ski Resort. In many respects, this arrangement has proved to be beneficial for the last 20 years. However, there are impacts, directly attributable to development of the Mission Ridge facility, which threaten wildlife in the Squilchuck and Stemilt basins. These impacts are cumulative, occurring over a long period of time, and were not identified by WNF in the prospectus and original lease documents (May 1965). The adverse effects result from zoning changes on private lands. What used to be forest and range now has commercial and residential use. This, in turn, has caused complete loss of lower elevation lands for wintering wildlife. Upper elevation developments are impacting summer/fall transition range, and important deer and elk migration routes. As one result, we have been faced with an increasing workload from wildlife damage claims and "problem" wildlife complaints.

00582

00582

James F. Torrence
September 22, 1986
Page 11

We feel that consideration of wildlife needs early in the planning of Mission Ridge could have prevented most of these impacts. By creating an all-weather road to the ski base area, providing power and other services (easy access), land development was encouraged and accelerated.

We are now faced with two major land development proposals near the Mission Ridge base area, well above existing developments. If construction occurs, we believe it will eventually eliminate all big game movement between the Stemilt, Squilchuck and Mission watersheds. Summer and fall use of these areas will be greatly reduced, as elk and deer seek scarce undisturbed sites. One of these proposals, Constellation Ridge Resort, has already requested development permits and zoning changes. The project would require access across WNF lands to tie into the Mission Ridge base area, also constructed on the Forest. We have made it clear to Wenatchee Mountain, Inc (Mission Ridge operation and management) that no access will be granted across Game Department lands for a destination resort, or any other year-round development. Our reasons have been clearly stated: we manage these lands primarily for the Colockum elk herd, and believe that other than winter-only use would have a significant detrimental impact on long-term herd survival.

Because Forest lands are central to the Constellation Ridge proposal, we feel that you should document potential impacts on habitats and wildlife use of the area. Of particular concern to us are long-term cumulative effects from ski resort and associated development. A mitigation plan should also be developed, to offset impacts on wildlife from use of Forest lands for commercial purposes. An appropriate method to address these concerns might be through rewriting the Term Special Use Permit, recently issued by WNF to Wenatchee Mountain, Inc. for continued operations at Mission Ridge (30 year lease). Your permit does not currently address our concerns. This agency recently issued a Term Special Use Permit (20 year lease) which does identify impacts and mitigation responsibilities for continued use of department lands. In your Forest Resource Management Plan, we ask that you address ski resort expansion and year-round use of WNF, cumulative long-term impacts from development of adjacent lands, and strategies to mitigate impacts on wildlife. We are currently developing a Colockum elk study proposal to address these and other concerns. We invite you to identify ways you might cooperate in this study

Information Needs

We favor a comprehensive monitoring plan which tracks model assumptions and parameters. Because you use indicator species to represent all forest wildlife, it is important to study habitat and populations for indicators, and also the linkages between these and non-indicator species. In addition, other data gaps exist. Big game winter use of the more heavily forested areas above specified winter range should be quantified and mapped. Human disturbance of mountain goats occurs, but little is known about threshold levels at which impacts become significant. Study of the effects of different sources of disturbance could point out useful management options. We also believe that

James F. Torrence
September 22, 1986
Page 12

grizzly bear and gray wolf recovery plans should be among those that you follow and monitor.

Land Acquisition and Exchange

Within the EW-1 management area description, in the section on lands, you state that public ownership of winter range is preferred. We strongly agree, and would support further acquisition of private inholdings within these areas as they become available. Recommended priorities in Entiat Ranger District are Swakane Canyon, Oklahoma Gulch, Entiat River Valley, and Twenty-five Mile Creek. Those in Naches Ranger District are lower Nile Creek drainage, lower Rattlesnake Creek drainage, Gold Creek, Rock Creek, and Garrett Canyon area along the slopes of Bald and Clemans mountains.

Although we support acquisitions of important habitat, we are concerned about the potential adverse effects of land exchanges. Creating large contiguous blocks of land can increase management options for Forest-owned portions, at the cost of giving up options on the privately-owned blocks. Net effects on fish and wildlife can only be judged on a case-by-case basis. We ask that you continue to consult us on any future land exchange proposals.

Specific comments follow

Proposed Plan

Page I-2, paragraph 3. Do model outputs and environmental effects in the plan include the Alpine Lakes area?

Page II-6, Production Potential. The existing setting does not represent maximum unroaded potential, because existing roads could be regraded and reseeded.

Page II-16, paragraph 2. We understand that all 4,667 miles are "system" roads, and do not include spurs. What is total road mileage on the forest?

Page II-19, Deer and Elk Winter Range. We believe that this method of populations actually underestimates deer and elk use on the Forest.

Elk Summer Range. We agree that some harvest could improve forage for elk. However, potential impacts from associated roading could easily outweigh the positive effects. Reduced livestock grazing would also be appropriate.

Mountain Goat Range. Other populations occur at Norse Peak and Henry M. Jackson wildernesses, and the Teanaway, Mt. Clifty and Keechelus Ridge areas.

Page II-20, Threatened, Endangered and Sensitive Species. Washington State status of Northern spotted owl is threatened, not sensitive. In addition, our

K-328

James F. Torrence
September 22, 1986
Page 13

Nongame Data System shows historic occurrences of grizzly bear and gray wolf at locations involved with timber sales (records enclosed). These species should also be used as indicators, and recovery plans discussed in your documents

Page II-21, Production Potential. It would be more helpful here to model and display production potential for all indicator species. Also, WFUD potential should be shown.

Demand. This discussion is limited to demand for deer and elk hunting. Non-consumptive use and hunting for other species are also important components of wildlife resource demand, and should be quantified. It would be appropriate to give expected WFUD's here.

Page II-24, Production Potential. Despite the uncertainty in these numbers, this presentation is more helpful than the preceding section on wildlife.

Page II-27, current timber harvest level. The figure of 176.8 million board feet appears to conflict with quantities given on pages II-29 (140.5), II-30 (184,164), and II-66 (131.9). These differences should be clarified.

Page II-31, Current Management Program. Your presentation of existing conditions is informative.

Page II-41, paragraph 1. The water quality data also show that standards are exceeded at times. We are concerned with potential local impacts on fish, so discussion of violations, rather than average compliance, is important

Page II-50, Current Management Direction. Hydraulic Project Approval is required for any prospecting activity within the ordinary high water mark. However, for panning and small sluice boxes, application need not be made, and the pamphlet 'Gold and Fish', published by this agency and Washington Department of Fisheries, serves as approval. The pamphlet must be brought to the work site.

Page II-54, Roads, Overview. The existing road density of 3.75 mi/sq mi has major impacts on wildlife. As discussed above, we strongly recommend maximums of 0.2 mi/sq mi in important wildlife areas, and 21 mi/sq mi elsewhere. On the next page, typical road densities proposed for currently unroaded areas are also high. In addition, even these numbers understate impacts if spur and dead-end road mileage is not counted.

Page II-65, Table II-25. Comparison with the table on page IV-26 would be possible if outputs were shown here for all indicator species. We ask you to include them and to show your model parameters, so that assumptions can be checked.

Wildlife Habitat, Big Game. Please explain model relationships which show potential increases of about 40% from a habitat potential over 6 times that of current program acreage.

James F. Torrence
September 22, 1986
Page 14

Big Game Estimates. Figures for 1986 seem to show that the current program is producing at maximum potential. Is this so?

Cutthroat Trout. Do numbers refer to smolts or adults?

Anadromous Commercial Harvest. Using pounds as units of measurement makes comparison with outputs on page IV-26 very difficult.

Page II-66, Table II-25, Trees. It is not clear how these figures are derived, or why they appear to conflict with those on pages II-27, II-29 and II-30

Page II-68, Recreation, 4. We strongly believe that this type of information on wildlife impacts from ORV's should be obtained before more large ORV allocations are made.

Page II-69, Wildlife. The NFMA requires that viable populations of all naturally occurring species be maintained, well distributed, within the planning area. Threatened or endangered species must be maintained, with no harm to individual animals.

Page II-70, paragraph 2. Population trend data for indicator species should also be gathered by WNF.

Page II-73, Roads. What assumptions do you make concerning road construction and recreation use? As far as impacts of roads on fish and wildlife, a great deal is already known (e.g.- Perry and Overly, 1977). However, information on ORV impacts would be helpful.

Page III-4, paragraph 2. We believe that avoiding activity in the riparian zone would be more beneficial for fish and wildlife, better for soils and water quality.

Paragraph 3. We are concerned that increased runoff would likely occur during peak flows, when it is less useful and brings greater risk of stream scouring. Throughout your documents, runoff seems to be treated as a benefit, though it may well be highly impacting.

Wildlife and Fish, paragraph 2. Fish and wildlife habitat are also affected by thinnings, reforestation and use of chemicals.

Page III-5, paragraph 4. We do not agree that Best Management Practices would assure no degradation of forest streams.

Page III-7, paragraph 1. We disagree that long-term, high-intensity timber production would improve big game cover/forage relationships. Paragraph 3. Snags and down wood would be reduced by this type of management, wildlife numbers would decrease.

00582

00582

James F. Torrence
September 22, 1986
Page 15

Page III-9, Water Quality and Quantity Cumulative Effects, paragraph 2. As stated above, we do not agree that Best Management Practices are sufficient to safeguard water quality

Page IV-3, Wilderness, 4 What kinds of facilities are to be developed? This goal appears to conflict with goal 20, page IV-5.

Page IV-5, Wildlife and Fish. These goals are generally well formulated. However, we believe that it would be appropriate to remove qualifying language from goal 1. Also, in goal 2, please add that viable populations of desirable non-native species will be maintained

Page IV-6, IV-7, Water, Soil and Air We support these goals.

Page IV-12, paragraph 1. As formulated, harvest intensities in riparian areas would impact wildlife.

Paragraph 2. Increased populations of species using snags and down woody material would occur only if you make more snags than now exist.

Fisheries, paragraph 3. In connection with the habitat improvement plan mentioned here, we look forward to contributing to future Sikes Act planning. Does the 3% increase of resident cutthroat trout take into account habitat degradation due to roads?

Page IV-20, Wildlife, paragraph 3. If snags and down woody material will only be managed for 60% of potential wildlife use, impacts will occur.

Page IV-21, paragraph 3. Availability of down woody material will be reduced for wildlife as well.

Page IV-24, Roads. We believe that you should discuss the need to control public use of forest roads in areas with densities greater than 1 mi/sq mi.

Forest Management Objectives. In contrast to what is stated, it appears that Table IV-1 shows resource outputs but not annual funding levels.

Page IV-26, Table IV-1. It would help a great deal to show fish and wildlife models and parameters, so that we could see how the numbers in this table are derived, and comment on the assumptions you use.

Chinook Salmon. As we mentioned above, numbers in this table are hard to compare to weight on page II-65.

Mule Deer, Elk These objectives are equal to maximum production potential shown on page II-65 Is this correct?

Bald Eagle. Does management for two nest sites comply with recovery plan objectives?

James F. Torrence
September 22, 1986
Page 16

Spotted Owl. The 79 pairs in 1987-1995 is almost equal to MMR level. Because risk factors exist for spotted owl, we question whether this is a proper management strategy

Page IV-27, Table IV-1, Sediment. Has any modeling been done for sediment impacts on resident and anadromous fish? Models are available from other forests.

Page IV-29, Table IV-1, Fuel Treatment. These figures are very close to your current program. This appears to conflict with the statement on page IV-22, paragraph 3, that burning of forest residues will be discouraged.

Page IV-30, Recreation Setting Have cumulative effects of more roads and recreation been included in big game output models?

Page IV-31, Trails. We strongly recommend that you re-evaluate this whole section, not only by ROS class, but also for conflicts with other resources, such as big game winter range and mountain goat habitat.

Page IV-44, Wildlife, paragraph 1. Carrying capacity would increase for some species, decrease for others. We also believe that road closures must accompany big game habitat management to make these efforts effective.

Paragraph 2. Effectiveness of old growth allocations depends on distribution and elevation, as well as adequacy of structural relationships.

Page IV-45, paragraph 3. As we have stated above, Best Management Practices do not prevent degradation of stream habitat. We strongly recommend that you develop a predictive model which includes the effects of your management activities

Page IV-47, Table IV-6. Unsuitable acreage appears to include non-forest land. We suggest that you retitle this column, or separate the non-forest component.

General Forest. Why have 166,895 unsuitable acres been included in the general forest prescription?

Page IV-49, Timber Yield Tables - Special. As stated above, we believe that 15-20 large trees per acre are not sufficient for old growth, big game cover or riparian protection prescriptions.

Page IV-52, Table IV-9, Age Class. Are shelterwoods put into the overstory or understory age class, or is average stand age used?

Page IV-59, Water, paragraph 1. Water quality standards will be met on the average. We are concerned with potential impacts on fish from events where standards are exceeded, and believe this should be discussed in your documents.

K-330

00582

James F. Torrence
September 22, 1986
Page 17

Page IV-62, paragraph 3. Could the Minimum Management Requirement (MMR) for dispersion be met under the forty percent criterion you mention here?

Paragraph 4. Another method to lessen soil compaction would be to limit designated skid trails to 10-15% of the sale area

Page IV-66, Roads, Management, paragraph 1. Another appropriate goal for road management is to reduce wildlife disturbance, harassment and road-induced mortality.

Page IV-71, Recreation Planning and Inventory, 7. We suggest that design of road and trail systems also be consistent with other resource objectives of the applicable management area.

Recreation Planning and Inventory, 8. We believe this standard should read, "Evaluate existing developed and dispersed recreation sites to determine if they meet the present and anticipated future public desires and resource capability, as well as other resource objectives of the applicable management area."

Page IV-85, 50. We maintain that it is within this agency's management prerogative to stock previously unstocked waters.

Page IV-86, 55. We support this standard. It should be applied forest-wide.

Page IV-89, Wildlife Surveys and Plans, 2. Population studies of management indicator species should also be conducted by WNF.

Page IV-90, table, Riparian. One-half of riparian snag-using wildlife species are cavity nesters in large snags (list attached). Wood duck are dependent on this class of habitat. Therefore, the riparian prescription should include an adequate large snag component.

Page IV-91, 13. We strongly recommend that you adopt standards for protection of important wildlife travel corridors. Perhaps these could be connected with riparian management criteria.

In Addition, we question whether modifiers such as "strive for", "consider", and "where possible" are appropriate for standards. It should be noted that this language only appears in the wildlife sections.

We also suggest that MMR's for management indicator species be included here.

Winter Range, b. Thermal cover units should be a minimum of 30 acres to provide a wind-free core. Winter Range c.

Winter Range, c. Open road density on winter range should be reduced to a maximum of 1 mi/sq mi, 0.2 mi/sq mi in certain key areas.

00582

James F. Torrence
September 22, 1986
Page 18

Page IV-96, Planning, 2. Please add: d. are within a special wildlife area.

Page IV-97, table. Is width measured in horizontal or slope distance? Minimums should be the direct influence zone slope distance equal to natural tree height.

3. Can your MMR dispersion constraint be met with 40% of a watershed in created openings?

4. We strongly recommend that burning not occur in riparian zones.

Page IV-105, Road Closures, paragraph 1. The USFS Region Six road management committee also identified consideration of the public's recreation experience as valid basis for road closures.

The final item in this list allows a closure if one "is necessary to protect or enhance National Forest resources." Because roads affect wildlife use so significantly, we believe it necessary to reduce open road densities to a maximum of 1 mi/sq mi forest-wide, and 0.2 mi/sq mi in key habitats.

Page IV-113, EW-2 Riparian. We recommend you add: d. Are in areas having special wildlife values.

Page IV-120, Recreation, Use Administration, Standard and Guideline, 2. Recreational objectives should be included in this standard, and in the corresponding Activity Statement entry.

Page IV-121, Non-Structural Habitat Improvement, Standard and Guideline, 2. Pruning and crushing could be added as appropriate vegetation management techniques.

Activity Statement, 1. Effectiveness index is not used anywhere else in the documents. Its derivation and meaning are not evident. What cover/forage ratio does an index rating of 80 imply? Are road densities considered?

Range Planning and Inventory, Activity Statement, 1. We question whether wildlife forage production should be subservient to livestock range use in a big game habitat management prescription.

Page IV-122, Timber, Regeneration Harvest, Standard and Guideline, 1. Definition of deer and elk thermal cover (Glossary, page 6L-23), should be incorporated into these standards. However, with shelterwood the predominant harvest method, it is unlikely that 15-20 large trees per acre would be sufficient to provide effective thermal cover. Increase use of selective harvest, and meet the specific canopy closure defined by Thomas, et al.

Intermediate Harvest, Standard and Guideline, 2. Within this wildlife prescription, snags should be managed at 80% of potential woodpecker habitat.

K-331

00582

James F. Torrence
September 22, 1986
Page 19

Reforestation, Activity Statement, 1. Delayed planting and wider spacing of seedlings would help to meet forage production objectives.

Timber Sale Preparation, Guideline 2, Activity Statement 1. We ask that you consult with this agency in establishing fawning, calving and kidding areas.

Page IV-124, Facilities, Local Road Construction, 1. Language should be added to this standard to establish a specific road density threshold. In EW-1 areas, where the emphasis is on big game, 1 mi/sq mi should be the maximum, with 0.2 mi/sq mi in key sections.

Page IV-125, Recreation Planning and Inventory, Standards and Guidelines, 2. The primary purpose of this management prescription is to maintain optimum riparian habitat for wildlife and fish and to protect wetlands. We believe that stronger language is appropriate for the standard on new campsite development.

Page IV-127, Regeneration Harvest, Activity Statement, 2. Please add that you will consult with this agency on decisions to concentrate leave trees away from the stream course.

Regeneration Harvest, Standards and Guidelines, 1. As we stated above, selective harvest would be more appropriate for riparian protection.

Intermediate Harvest. Please add 3. Manage snags for 100% potential woodpecker population.

Water, Soil, and Air, Improvement, Standards and Guidelines, 1. Enhancement of wildlife habitat would also be appropriate.

Page IV-128, Minerals and Geology, Processing of Site Specific Development Proposals, Standards and Guidelines, 4. The riparian zone is not appropriate for disposal of toxic mine tailings

Page IV-129, Facilities, Local Road Construction, Standards and Guidelines, 1. Because this is a wildlife prescription, better language for this standard would be, "Locate roads outside the zone wherever possible."

Standards and Guidelines, 3 Please add, "Maintain screening vegetation adjacent to all roads in the riparian zone."

FA&O Construction and Reconstruction, Standards and Guidelines, 1. As with roads, these structures should be located outside the zone whenever possible.

Standards and Guidelines, 3. Transfer systems should be located outside the riparian zone.

00582

James F. Torrence
September 22, 1986
Page 20

Page IV-134, top of page, Standards and Guidelines, 2. In all general forest prescriptions, you should mention that snags will be managed at 60% of potential woodpecker habitat.

Page IV-141, Management Prescription OG-1. As discussed above, we have major concerns with this prescription being applied to all old growth areas outside of wilderness. We believe that not enough is known about managing timber to produce critical old growth functions.

Description, paragraph 2. One standing snag per acre does not meet minimum management requirements (MMR's) for pileated or Northern three-toed woodpecker. MMR's for marten specify 6 down logs per acre.

In addition, we believe you should specify no activities in this management prescription during breeding season, and minimum canopy closures of 50% for marten, 65-80% for spotted owl.

Wildlife and Fish, Wildlife Surveys and Plans. Surveys should be made of species with minimum management requirements, to see if habitats are occupied.

Page IV-142, Timber, Regeneration Harvest, Activity Statement, 1. To account for future mortality, more than a minimum number of dominant trees should be left per acre.

Activity Statement, 2, a. Spotted owl inhabit areas with a canopy closure of 65-80%. b. MMR's for pileated and Northern three-toed woodpecker specify 2 snags per acre. c. MMR's for marten require 2 snags and 6 down logs per acre. Canopy closure must be at least 50%.

Intermediate Harvest, Activity Statement, 1. We believe this should read, "Thin to maintain a multi-storied, uneven-aged stand (see old growth description)."

Page IV-143, Intermediate Harvest, Standards and Guidelines, 2. The spotted owl management plan in the Regional Guide specifies that dead and dying trees will not be removed.

Timber Stand Improvement, Activity Statement, 1. We ask you to state that chemicals will not be used in this prescription.

Timber Sale Preparation, Standards and Guidelines, 1. Activities should be strictly timed to avoid breeding season.

Page IV-145, Initial Attack Suppression..., Standards and Guidelines, 1. Here and in the following standard, we ask that you add "which maintains multi-layered, uneven-aged stands."

K-332

James F. Torrence
September 22, 1986
Page 21

Page IV-147, Wildlife and Fish. It would be helpful here to add a standard specifying that development of ski areas and other recreational sites will avoid key wildlife habitats.

Page IV-152, Timber. In this prescription, salvage harvest should maintain enough snags for 60% of potential woodpecker habitat.

Page IV-161, Non-Structural Habitat Improvement, Activity Statement, 1. It would be helpful here to state forage level allocated to wildlife.

Page IV-162, Timber, Intermediate Harvest, Standards and Guidelines, 2. In this prescription, harvest should maintain enough snags for 60% of potential woodpecker habitat

Page IV-163, Water, Soil, and Air, Improvement, Standards and Guidelines, 1. We believe that all actively eroding stream channels should be rehabilitated.

Standards and Guidelines, 3. We suggest that you strengthen this wording by changing "consider" to "conduct".

Page IV-171, Wildlife and Fish, Non-Structural and..., Standards and Guidelines, 1. Please add: "Manage snags at 100% potential woodpecker habitat level."

Page IV-176, Wildlife and Fish, Non-Structural Habitat Improvement, Standards and Guidelines, 1. Please add: "Manage snags at 100% potential woodpecker habitat level."

Page IV-182, Wilderness, Standards and Guidelines, 1. It would be helpful to add: "Regulate human activities where necessary to prevent habitat degradation and wildlife harassment."

Page IV-183, Intermediate Harvest, Standards and Guidelines, 2. In this prescription, harvest should maintain enough snags for 60% of potential woodpecker habitat.

Page IV-189, Intermediate Harvest, Standards and Guidelines, 2. In this prescription, harvest should maintain enough snags for 60% of potential woodpecker habitat.

Page IV-193, Wildlife and Fish, Non-Structural and..., Standards and Guidelines, 1. The opportunity exists to seed utility corridors with wildlife forage in winter range and key elk summer range.

Page IV-197, Range. In wilderness, we believe it would be appropriate to phase out livestock allotments as they expire.

James F. Torrence
September 22, 1986
Page 22

Page IV-203, Wildlife and Fish, Non-structural Habitat Improvement, Standards and Guidelines, 1. In this prescription, snags should be managed for 80% of potential woodpecker habitat.

Page IV-204, Intermediate Harvest, Standards and Guidelines, 2. The 80% criterion mentioned in our previous comment should be stated here.

Page V-4, paragraph 2. We strongly recommend that you also monitor your model parameters to see if assumptions and predictions are valid.

Page V-13, Table V-1, Wildlife. As we stated in the previous comment, model parameters and assumptions should be monitored.

Wildlife, 6.1. Another important monitoring component is to determine occupancy rates of old growth indicator species.

Wildlife, 6.7. Our spotted owl studies have been completed; additional census work by WNF will have to be undertaken to fulfill this element.

Page V-14, Fish. Other elements we believe you should add are monitoring of SCHI model parameters against fish population samples, and sediment/impact linkages.

Draft Environmental Impact Statement

Page S-4, Wildlife, paragraph 3. We have enclosed occurrence records of grizzly bear and gray wolf sightings from areas of recent timber sales on WNF.

Page S-5, Roads, paragraph 1. Road densities of 3.75 mi/sq mi have significant impacts on wildlife, especially big game. We recommend that closures and/or regrading and reseeding be used to reduce this figure.

Page S-9, Table S-2. From the range of figures, it appears that model outputs of anadromous fish do not account for sediment increases.

Page S-13, Fisheries, paragraph 1. Since resident fish numbers should be a better measure, it would be better to include them in the Table S-2 display.

Page S-14, Table S-5. With fairly large differences in allocations among alternatives, it is unclear why permitted grazing levels vary so little.

Page S-16, Probable Adverse Environmental Effects That Cannot Be Avoided, paragraph 2. Management activities can also have long-term effects on water.

Page S-17, Short-Term Uses vs. Long-Term Productivity. We believe it would be good to discuss old growth in this context. Cutting old growth may cause permanent loss of valuable attributes. In contrast, dedicated stands form a gene pool resource, harbor insect inhibitors (birds), serve as spore source of

James F. Torrence
September 22, 1986
Page 23

nitrogen-fixing fungi (spread by small mammals), and so maintain long-term productivity of the forest.

Page I-8, Planning Problem #4, paragraph 1. We believe that more attention needs to be given to the effects of roads on wildlife.

Page II-3, paragraph 2. Impacts should be compared to existing conditions rather than current direction.

Page II-15, Water, paragraph 1. In each alternative water quality standards would be met on the average. We feel that it is important to know potential adverse effects of those times when standards are not met.

Page II-16, Soil. Sediment volumes increase significantly for all alternatives in years 50-150. A question that this fact poses is what future activity levels bring such sediment increases. It would help to see model parameters.

Page II-48, Minerals. Withdrawal figure of 12,826 acres disagrees with numbers given in the accompanying table.

Page II-71, Table II-1 Under Alternative F, acreages for unroaded, motorized and non-motorized recreation appear to be in conflict with percentage breakdowns listed immediately below.

Page II-72, Table II-1, Management of Areas That Are Presently Undeveloped. We believe that these percentages are somewhat misleading. Putting roads in these areas will cause them to cease being roadless. A more revealing figure would be the number of inventoried areas you plan to leave truly roadless in each alternative.

Page II-74, Table II-1, Water Quality and Quantity, Water Quality. As we have stated above, Best Management Practices do not eliminate degradation of water quality.

Page II-90, table. Roaded dispersed recreation is not compatible with big game emphasis (EW-1) if road densities are over 1 mi/sq mi. Riparian wildlife emphasis (EW-2) would have the same potential conflict; in addition, developed recreation would usually be inconsistent with this prescription.

Page II-92, Management Area OG-1, Description, paragraph 2. We question whether 10-15 large trees per acre would be sufficient to meet canopy closure needs for MMR species. Pileated and Northern three-toed woodpecker require two snags per acre. Marten need a canopy closure of at least 50%, and 6 down logs per acre. Spotted owls should have a canopy closure between 65-80%.

Page II-95, paragraph 1. We commend your intention to combine compatible facilities to the same corridor whenever possible.

James F. Torrence
September 22, 1986
Page 24

Pages II-100, II-101, Unroaded Motorized Use and Capacity. We believe that wildlife are adversely affected by widespread ORV use. Because of this, we do not support unroaded motorized use allocations which are 2-5 times projected demand.

Page II-108, Table II-3a, Spotted Owl. Our research indicates the average amount of old growth used by owls in Washington is 4500 acres.

Page II-108, Table II-32, Marten. The figures given here match those for pileated woodpecker. However, the two species are distributed at different distances. In addition, MMR's require at least 894 marten. This may be a misprint, or incorrect parameters may have used in your model. Please explain how the numbers of animals were calculated. Both pileated woodpeckers and owls need to be distributed differentially in FORWET and FORDRY.

Page II-109, Table II-3a, Wildlife Habitat Improvement. There are fairly large differences across alternatives in this category as well as in the magnitude of timber activities. However wildlife-related PNW (EIS, page II-152, Appendices, page B-173) does not change. We believe that this result is clearly erroneous.

Page II-124, Table II-3b. In many categories, comparing outputs and effects to current direction rather than existing conditions makes impact assessment more difficult.

Pages II-142, II-143, Table II-3b, 15. Sensitive Species. We understand that state listed species are required to be managed with the same considerations as federally listed wildlife.

16. Game Populations and Distribution. It appears that distribution information was inadvertently left out.

17. Non-Game Populations and Distribution. This category was not included for alternatives F-I, on page II-143.

Page II-147, Present Net Value. As discussed in the main body of this response, wildlife are a publicly-owned resource. Losses caused by management actions represent costs which affect net public benefit calculations.

Page II-148, paragraph 4. Here, and elsewhere in your documents, you treat increases in water yield as an unqualified benefit. We believe that runoff timing could easily cause extra flow to be impacting, and without holding structures, unavailable to downstream users.

Page III-8, pie charts. It would be helpful here to include a breakdown of fish and wildlife oriented recreation for comparison.

Page III-12, Off-Road Vehicle (ORV) Use, paragraph 1. The figure 192,000 causes us to question your projected average of 346,000 RVD's for unroaded motorized use, 1980-1990, in Table III-3.

James F. Torrence
September 22, 1986
Page 25

Page III-38, Old Growth Forests. As stated in the main body of this response, we believe that your definition of old growth does not meet minimum management requirements. Additional constraints are needed for percent canopy closure, and numbers of snags and down logs per acre to meet the individual needs of each species.

Page III-39, Dead and Defective Tree Habitats, paragraph 1. It would be helpful to outline possible methods for eliminating snag removal by firewood cutters. These might include changes in permit language, increased enforcement, and education programs.

Cliff, Rim, Caves, Burrows, and Talus, paragraph 2. Talus habitats can also be affected by alteration of the hydrologic regime due to harvest of timber above and adjacent to them.

Page III-40, Deer and Elk Winter Range, paragraph 1. We feel that your technique of proportioning game populations by percentage of WNF land within game management units actually understates the number of animals that use the Forest at least part of the year. We believe that more realistic estimates would be 29,000 deer and 14,500 elk, with harvests of 3450 and 4500, respectively. In addition, the department goals generally differ from ten-year averages.

Page III-42, Elk Summer Range. Consideration should also be given to increasing carrying capacity by limiting livestock allocations.

Threatened, Endangered and Sensitive Species. Should grizzly bear and gray wolf receive fuller treatment? Both have occurred on the Forest (see attachments).

Page III-43, paragraphs 1-4. We agree with your use of the single-paired SOMA concept.

Table. Dispersal distances should be measured center to center. Also, it is unclear how these figure relate to the output table on page II-108, where numbers of marten and pileated woodpecker are equal, although dispersal distance constraints differ.

Page III-44, Demand for Wildlife, paragraph 1. As discussed above, we believe that more accurate harvest estimates would be 3450 deer, and 4500 elk

Pages III-44, III-45. In your discussion of recreational use of wildlife and fish, it would be helpful to show WFUD's and their corresponding value.

Page III-58, Figure III-9. This diagram is very helpful.

Page III-75, paragraph 1. We are also concerned with impacts from those instances when water quality standards are not met

James F. Torrence
September 22, 1986
Page 26

Page III-81, Nutrient Losses. Removal of snags and down wood also causes loss of nutrients.

Page III-86, Recreational Minerals, paragraph 2. As mentioned earlier, Hydraulic Project Approval is required for any instream prospecting activity. For panning and small sluice boxes, the pamphlet 'Gold and Fish' serves as Approval. The pamphlet can be obtained by contacting any Department of Game office.

Page III-118, Recreation Setting/Wildlife, paragraph 3. Wildlife losses also occur through poaching and when animals are hit by cars.

Paragraph 5. Please add "and direct mortality" after "factor".

Paragraph 7. It would be helpful to show wildlife-related WFUD's and associated value.

Recreation Setting/Fisheries, paragraph 1. What is the imputed value of this recreation?

Page III-123, Wild, Scenic, and Recreational Rivers/Wildlife, paragraph 3. We believe that restrictions on activities from these designations would lower impacts on wildlife.

Page III-133, Wilderness/Wildlife. We believe your statement, that wilderness designation has very little effect on wildlife, is clearly wrong. Maintaining natural ecosystems and natural levels of all wildlife species is a definite benefit of wilderness designation. The absence of roads and minimization of human disturbance assures long-term maintenance of populations.

Wilderness/Vegetation Trees, paragraph 1. Management activities in wilderness which do affect natural vegetation are livestock allocations and mining.

Page III-135, Wildlife/Wildlife, paragraph 2. Your statement that indicator species will be monitored does not appear to be reflected in the monitoring plan (Plan, page V-13).

Page III-136, Wildlife/Vegetation: Trees, paragraph 3. Known adverse effects from harvest activities include loss of old growth acreage.

Washington State status of spotted owl is threatened.

Page III-138, paragraph 1. Another mitigation possibility is to restrict permitted mining to certain seasons.

Paragraph 3. We suggest that operating plans definitely be rejected if there is an unavoidable conflict with endangered species habitat.

James F. Torrence
September 22, 1986
Page 27

Wildlife/Roads, paragraph 3. Roads also lead to increased legal and illegal kills of game animals. To contradict the last sentence, we believe that fairly good information is available on the extent of reduced wildlife use of habitats adjacent to forest roads, and we refer WNF to Perry and Overly, 1977, Thomas et al., and Brown et al. for quantifications.

Paragraph 4. We believe that for most species benefits from created edge have been outweighed by impacts.

Wildlife/Social/Economic. Adverse effects on big game winter range also lead to direct mortality.

Page III-139, paragraph 2. It would be helpful to model sediment/fish interactions.

Paragraph 6. How many K-V fisheries projects were funded in fiscal year 1986?

Page III-142, Fisheries/Roads, paragraph 1. Roads are the major cause of stream sedimentation and loss of habitat, as you point out on page III-150, Soil/Roads, paragraph 1.

Page III-143, Fisheries/Social/Economic, paragraph 1. It would be informative here to include the value of fishing WFUD's.

Page IV-3, Developed Recreation. We do not agree that more roads inevitably mean more recreation opportunity, and firmly disagree that the relationship is a proportional one. Use of an area can drop due to relative crowding, because of wildlife avoidance of roads, or from other intangible factors.

Page IV-9, Conflicts with Other Agency Plans and Policies, paragraph 2. Our goals are more comprehensive than stated. Species population and road management goals may also be in conflict with these and other alternatives. We recommend WNF obtain a copy of WDG Region 3 operations plan.

Mitigation Measures, 5. Habitat protection is an important reason for road closures.

Page IV-31, Alternative B, paragraph 3. We believe there are only two species dependent on early successional stages: American kestrel and Western bluebird.

Page IV-32, Mitigation Measures for Wildlife, paragraph 2. It should be acknowledged here that mitigation would not be effective for all species of wildlife. Other measures, not mentioned, involve road location and design, size, shape and location of harvest units, protection of critical habitats, protection of snags, and rotation length.

Page IV-35. We strongly recommend that you develop a model which relates populations to management activities and resulting sedimentation.

James F. Torrence
September 22, 1986
Page 28

Page IV-37, paragraph 5. We do not agree that Best Management Practices can assure no significant reduction in stream habitat.

Page IV-41, paragraph 1. As we stated above, we believe that 15-20 trees per acre would not be sufficient to provide optimum wildlife habitat.

Is the 10% harvest restriction given in terms of volume or acreage?

Page IV-52, last paragraph. It should be noted that this agency has fed elk in the winter to make up for increasing losses of winter range to agriculture and development.

Page IV-56, Mitigation Measures for Vegetation: Forage, paragraph 4. We agree that grazing management can make improvements over conditions from unmanaged livestock use. We do not agree that it is preferable in all cases to no livestock allotments.

Page IV-62, bottom paragraph, left column. Here you appear to allow that Best Management Practices do not prevent stream degradation.

Page IV-72, Mitigation Measures for Water, paragraph 1. Your statement here about the effectiveness of Best Management Practices conflicts with the first paragraph in the section on direct effects of each alternative, located on this same page.

Page IV-73, graphs. It would be helpful to extend all these graphs through the entire planning horizon.

Page IV-92, last paragraph. As we discussed above, road densities should be a maximum of 0.2 mi/sq mi in key wildlife areas, and 1 mi/sq mi elsewhere.

Page IV-93, Alternative's Conflicts with Other Plans and Policies. As given, all alternatives may be in conflict with this agency's road management goals of 1 mi/sq mi forest-wide, and 0.2 mi/sq mi in special areas (open road density).

Page IV-103, last paragraph. It would be helpful to show model parameters.

Page IV-104, Recreation Setting/Fisheries, paragraphs 2, 3. The implication here that increased roading is key for fishing opportunity is contradicted by outputs listed on page II-104, showing that Alternative E gives the most WFUD's.

Page IV-106, Recreation Setting/Minerals, paragraph 1. Impacts are described as temporary; however, coal mining operations often last for decades.

Page IV-109, Wild, Scenic, and Recreational Rivers/Wildlife, paragraph 1. We believe that activity restrictions due to these classifications would generally benefit wildlife.

00582

James F Torrence
September 22, 1986
Page 29

Page IV-114, Scenery/Wildlife, paragraph 3. We believe that lower road densities in alternatives E and F would provide better wildlife viewing.

Page IV-118, Wildlife/Wildlife, paragraph 2. Old growth areas provide critical forage for deer and elk during severe winter weather.

Paragraph 3. Forage is reduced, not eliminated, in old growth.

Page IV-121, Wildlife/Soil. Productive soil leads to productive vegetation for wildlife.

Wildlife/Roads, paragraph 2. According to Perry and Overly (Washington Department of Game, 1977), Deer use increased 44% at a distance of 1/8 mi. from open roads. Elk use increased 44% at 1/8 mi., and another 25% in the next 1/8 mi. Even these figures are simplifications - original data might be used in more detail within this section. Direct effects of roads on wildlife also include poaching and vehicle-caused mortality.

Page IV-122, Wildlife/Social/Economic. It would be helpful here to give the figures for wildlife oriented recreation expenditures.

Fisheries/Vegetation Trees, paragraph 3. Temperature increases can also have detrimental cumulative effects downstream of harvest activity. In addition, openings allow greater cooling during severe winter weather.

Page IV-123, paragraph 2. As stated above, we believe that your standard of 15-20 trees per acre leaves insufficient canopy for optimum riparian habitat. We recommend selective harvest for riparian areas.

Fisheries/Vegetation: Forage, paragraph 1. We question whether livestock use would improve plant cover to the benefit of fish.

Paragraph 4. You state here that shelterwood sites are unsuitable for livestock forage. This seems to conflict with your plans to make shelterwoods the predominant method of riparian harvest and to continue with riparian grazing allocations.

Page IV-124, Fisheries/Water, paragraph 1. Increased yields are likely to occur during peak flows, making impacts more probable than benefits.

Paragraph 2. The direct relationship you mention does not appear to be used in your model.

Fisheries/Soil. We do have concerns for sedimentation impacts on fish habitat. Taken over the entire planning horizon, all alternatives show increases which, together with background level, could cause significant localized impacts.

K-337

00582

James F. Torrence
September 22, 1986
Page 30

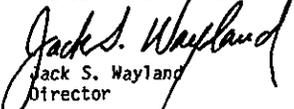

Fisheries/Roads, paragraphs 2, 3. As stated above, we disagree that best management practices give sufficient protection. Measurable changes in fish production do not appear to be shown by your model outputs.

Page IV-143, paragraph 4. Vegetation management activities also adversely affect wildlife, although we agree that some species benefit from openings. In addition, there will be a continuing reduction of large tree component snags, down wood, and large organic debris for stream habitat. Species dependent on these features will be impacted.

Thank you for the opportunity to comment on the WNF document. We trust you will find our information useful in preparing final plans.

Sincerely,

Mr Clifford Rushton
Forest Plan DEIS Coordinator
Department of Ecology
PV-11
Olympia, Washington 98504-8711

Dear Mr Rushton

Re Wenatchee National Forest DEIS

Considering the issues and concerns on this forest, Alternative C provides a good balance of recreational opportunities. Dispersed, unroaded recreation receives appropriate acreage allocations for both motorized and nonmotorized recreation. This option supports the State ORV Plan by providing for motorized recreation in unroaded areas.

Future recreation facility needs as addressed in the Statewide Comprehensive Outdoor Recreation Plan for this region are also answered by this Alternative. An increased need for camping facilities and motorized trail recreation by 1990 are met in this option. Greater protection for scenic values is allowed and more acres are allocated to game range. Fisheries are also enhanced.

One qualifier--you have assumed demand for recreation facilities will grow commensurate with population growth. Be aware that recreation demand can and often does exceed population growth and must be anticipated.

Thank you for the opportunity to comment on the plan.

Sincerely,

LORINDA A ANDERSON

Re Wenatchee Forest Plan and
Draft EIS

Dear Mr. Rushton:

A staff review has been completed of the above referenced draft environmental impact statement and proposed land and resource management plan. The document adequately considers known and anticipated cultural resources and the potential for impact to these. The precautions proposed to identify cultural resources and to avoid or mitigate anticipated impacts to identified or unidentified cultural resources are adequate.

Thank you for this opportunity to comment.

BRIAN BOYLE
Commissioner of Public Lands

OLYMPIA WA 98504

00342

September 2, 1986

Mr. Don Smith
Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, WA 98801

Dear Mr. Smith:

In our recent letter of response to the Okanogan National Forest Draft Environmental Impact Statement (DEIS) and Plan, we supported and echoed recommendations from other states in the Pacific Northwest Region that no final forest plans be issued until all drafts have been made public. Our concern is that the sustainable harvest or management of other resources on each of the national forests could change appreciably with significant cumulative effects statewide. Because of this, we wish to reiterate our support for this recommendation to you and defer selection of a preferred alternative at this time.

In our comments, we will address the No Action Alternative, Economic Efficiency, Alternatives Assessment, discussions specific to Hydrology and Cumulative Effects, Geology and Mineral Resources, Natural Heritage and General Observations.

NO ACTION ALTERNATIVE

Alternative A, the "No Action Alternative," appears to be a continuation of the recent programmed sale of timber. However this is not the case, since during the period 1975-1984 the offering of timber totalled 184 million board feet annually. This is in contrast to the "No Action Alternative" which would offer for sale 140.5 million board feet annually. A decline of over 20 percent is a significant change. Even if we compare this with the volume sold (1975-1984), the total is 164 million board feet annually. In this instance the decline is nearly 15 percent which is still a substantial change.

The phrases "current level," "current management direction," and "current planning data" should be clearly explained for a better understanding of how the "No Action Alternative" was created.

Mr. Don Smith
September 2, 1986
Page 2

ECONOMIC EFFICIENCY

Strict economic efficiency is determined by maximizing present net value (PNV) for the market-priced products. To do this, it is essential to include the benchmark alternative labeled "Maximum Present Net Value Based on Established Market Price." Once this is determined, other alternatives can be assessed against the economic efficiency alternative to determine the value of market goods given up.

If it is recommended, for instance, that 2,000 acres of old-growth be reserved to maintain a pair of northern spotted owls, the cost of this decision can be calculated by determining the value of the market-priced goods lost. This seems to be a sensible way to approach the valuation of the nonmarket goods.

Present net value (PNV) is used in the Plan/DEIS for valuing both commodity products and nonmarket goods. Only the commodity goods should have dollars assigned to them. For maximization of social net benefit, implicit dollar values should not be added to market-derived dollar values. The combined value does not provide a meaningful measure for choosing between alternatives. Nonmarket values should be arrayed separately for the purpose of the EIS analysis.

ALTERNATIVES ASSESSMENT

Community effects are a concern for federal and state government. Revenues to counties, jobs, and income effects, are all important. An effort should be made to increase these when feasible. Also, impacts beyond the first decade should be considered. With the departure for one decade, there may be an initial boost, which is then followed by a substantial decline. Alternative I is one which on the surface looks good in terms of first decade harvest, but has a substantial harvest decline in subsequent decades.

The alternatives were assessed using a simple rule of thumb--all alternatives that do not have positive community effects are rejected. Using this rule, Alternatives A, C, E, F, and G were all unacceptable. Alternative I was also rejected because of the departure feature of the timber harvest over time. Alternative H (timber production maximization) had a low present net value. For this reason it seems appropriate to reject it from further consideration.

The alternatives which appear to make the most sense in terms of a continuation of timber as a commodity resource and an important community stability resource are Alternatives B and D.

K-340

Mr. Don Smith
September 2, 1986
Page 3

Of these two alternatives B would have much greater impacts on the nonmarket resources which is clearly a multiple-use resource concern. Alternative D would continue to provide stability to the local economies at the recent timber harvest level and also allows for flexibility with respect to the nonmarket resources.

HYDROLOGY AND CUMULATIVE EFFECTS

The DEIS for the Wenatchee National Forest simplifies the impacts on water into the categories of water yield changes and sedimentation. The simplification of complex hydrologic systems seems to be a valid approach for long-term strategic planning.

In the Plan/DEIS, long-term projections of sediment yield show that maximum levels occur after as much as 150 years. Although it is not specifically stated, recovery rates must be expected to be very low. These projections seem to be unrealistic.

K-341
IV
The issue of cumulative effects was also simplified. It is assumed that basins with more timber harvesting scheduled and having a larger proportion of area in private ownership have a greater risk of cumulative effects. Further discussion of what cumulative effects are and how they occur would provide a better insight about their significance when comparing alternatives.

GEOLOGY AND MINERAL RESOURCES

An important issue to the Department is access to land for mineral exploration and mine development. The Department is in support of protecting and improving the opportunities for mineral exploration when consistent with the protection of other resource objectives. Our Geology and Earth Resources Division staff may have information on specific areas in the Wenatchee National Forest of mineral interest. Please feel free to call Ray Lasmanis, Division Manager, at (206) 459-6372 in Olympia.

NATURAL HERITAGE

Special Plants

The Wenatchee National Forest has the highest concentration of endangered, threatened, and sensitive plant species of any national forest in Washington. We agree with Forest Service policy to maintain viable populations of all sensitive plant and animal species.

Mr. Don Smith
September 2, 1986
Page 4

Since management for other resources potentially conflicts with maintaining viable populations of sensitive plants, standards and guidelines should be developed.

Research Natural Areas

The Research Natural Area Program is strongly supported by the Department as part of the cooperative effort of federal, state and private groups to establish a statewide system of natural areas. The natural area needs, outlined in the State of Washington Natural Heritage Plan (WDNR 1985), will be best met by all the participants inventorying for, and designating, the best examples of representative ecosystems and rare species populations on their lands. On the Wenatchee National Forest this means low- and mid-elevation forests be considered, especially those that cannot be located on other national forests or state and private lands.

Special Interest Areas

The discussion of the Tumwater Botanical Area is accurate as far as it goes. The area is also habitat for the only known population of Hackelia venusta (showy stickseed). This species is soon to be proposed for listing as endangered under the Endangered Species Act. It is quite unusual for a botanical area to be designated for other reasons and then be found to contain an endangered species. A management plan should be developed for this area which specifically takes into account this rare plant. Publicity regarding the area as being habitat for the species should avoided.

The technical staff of our Private Forestry and Natural Heritage Division has prepared detailed comments relating to natural heritage resources. These will be sent to you under separate cover.

GENERAL OBSERVATIONS

We would expect the plan to ensure operations be conducted to equal or exceed the requirements in the Forest Practice, Forest Fire Protection, Surface Mining, and Forest Insect and Disease Control state statutes and subsequent regulations. Additionally, we would expect the transportation system management program not to interfere with the access for Department-managed lands.

Overall, the Wenatchee National Forest Plan provides a good basis for making sensible decisions of how to manage the national forest during the next 10-15 years. The maps were well done, especially the color coding, which is helpful for understanding the differences between the management alternatives. We did note that

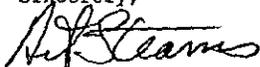

00342

Mr. Don Smith
September 2, 1986
Page 5

the map provided for the preferred alternative does not reflect the ownership changes brought about by recent USFS-DNR land exchanges in Chelan and Kittitas counties.

We appreciate this opportunity to comment on the Wenatchee National Forest Plan and DEIS. If you would like further clarification, please call Glenn Yeary, Manager of the Analysis and Planning Section in Olympia at (206) 586-4435.

Sincerely,

Art Stearns
Supervisor

RE Proposed Land and Resource Management Plan and Draft Environmental Impact Statement, Wenatchee National Forest

Dear Mr. Smith

The Board of Chelan County Commissioners have had an opportunity to review the proposed plan and draft environmental impact statement. Prior to providing specific comment we would like to point out that due to the volume of material provided, the nine alternatives offered and the numerous management issues discussed within each alternative, it becomes extremely difficult to provide specific and detailed comment. We have, therefore, attempted to confine our comments to three general areas of concern rather than any one alternative. We are hopeful that these concerns will be addressed in the final alternative developed.

The first area of discussion can be generally categorized under economic concerns and/or issues. The plan contains a wide range of potential impacts relating to employment in the wood products industry, however these projections are based on some rather old economic data. We would suggest that the economic model be updated in order that more accurate projections might be presented. With better quality data perhaps all parties might better understand the implications of the various proposals. In any event we would suggest that the final plan be structured so as to have the most positive impact on the wood products industry in Chelan County, consistent with the comments which follow.

Also in the area of economic impact we find very little discussion of the value of tourism and recreation which have been long recognized as important aspects of the local economy. Certainly the alternative selected and management direction provided for such issues as developed recreation, view sheds, cultural resources, etc., will have the potential to significantly affect the tourism and recreation industry. It is equally important to include in the final plan, an RE-1 category recognizing the expansion and development potential of Echo Valley and the Stormy Mountain ski areas since winter sports help expand our recreation season.

Don Smith
September 29, 1986
Page 2

Under the general heading of water we have concerns relating to both water quality and water quantity. With regard to water quality, it is important to recognize that the alternatives which have the potential to significantly increase sediment loads will have an impact on local growers. The area of most concern would be increased maintenance costs for irrigation pumps and sprinkler nozzles. This is a problem today for growers in the Entiat Valley and along Mission Creek.

Water quality is an important issue throughout the County, but perhaps more so in the Icicle Valley since that stream serves as the municipal supply for the City of Leavenworth. This Board has serious reservations with the concept of substantially expanding small existing campgrounds in that drainage, particularly since there is some potential to seriously degrade water quality. Certainly there must be other campgrounds better suited to accept expansion impacts than those within the Icicle Valley.

Another concern with water quantity relates to the potential for increasing water yield from the national forest. If increased yield means impacting the timing of runoff, this may seriously affect the problem of maintaining in-stream flow requirements for local rivers. In the event that we are unable to adequately maintain in-stream flow requirements local landowners will immediately suffer affects.

Our final comments come under the general heading of off-forest impacts. There seems to be very little information contained within the proposed management plan or the draft environmental impact statement regarding the wild, scenic and recreation river classifications and more particularly how those classifications may affect private lands within the national forest boundary. Before such proposed classifications are enacted, it is extremely important that the local land owners have a clear understanding of the issues.

The last off-forest issue relates to winter range. While there are substantial benefits to increasing deer and elk numbers, we do not have a clear understanding of potential impact this may have on off-forest winter range. There certainly should be additional discussion on this matter particular with those land owners who might be most directly affected. One alternative may be to examine the plans for optimum forage production and utilization by commercial livestock and consider modifications in consideration of the winter range issue.

We wish to thank you for the opportunity to review and comment on the proposed plan and draft environmental impact statement. The plans of the Wenatchee National Forest have rather direct bearing on Chelan County and we look forward to working with you as a final document is developed.

Sincerely,

John S. Wall

Re: Wenatchee National Forest Management Plan

Dear Mr. Smith:

Your recently published National Forest Plan with Alternative "C" as your preferred alternative, indicates that the losses to Kittitas County could be substantial. We are also concerned that the actual losses may be greater than what you indicate.

We do believe that a balanced timber harvest is essential, and that job opportunities be provided through the harvest and manufacturing of forest products, and the availability of continued mining activities.

Our position on the Management Plan is inescapably tied to the unresolved issues of the Spotted Owl. We would prefer that timber yields not be reduced until it is determined how many acres of timber will be set aside for each pair. It is difficult to address this plan until a determination is made on this issue. We believe that your preferred alternative be modified to enhance all the values that exist now in the Wenatchee National Forest. After your determination of the SOMAS, the allowable cut should be maintained at its present allocation. This allowable cut would insure the availability of timber and would still provide a compatible multiple use balance for all the other amenities that exist on the forest.

We recognize that increasing the allowable cut from that proposed in preferred Alternative "C" may affect other areas. Our concern is with the subsequent impact that road construction would have on continued resource management. We recommend strongly that all unnecessary new roads be closed to motorized activities following harvest and that you dedicate these areas for dispersed recreation. This modified proposal could also be an enhancement to wildlife resource.

Mr. Don Smith
Page 2
September 30, 1986

We strongly urge your modification of Alternative "C" to reflect the concerns we have expressed. Your implementation of these suggestions would insure the future of our Region.

We would also like to express our gratitude to you for the time you have taken to explain the Management Plan to us.

Sincerely,

Re FOREST SERVICE PLAN

Dear Don:

K-345 You have our sympathy and our gratitude. Sympathy because we are only too aware of the hazards of culling a single recommendation from a broad range of diverse positions. Gratitude for the fine work you and your staff are doing in informing people of the alternatives available to make the forest serve the most people in a reasonable manner. Also, we thank you for sending a team of your people to meet with us.

We have met with representatives from most groups involved in creating positions within the range of alternatives. We have met with our own planning staff, attended public meetings and followed comments which occurred within the media. We feel we are now prepared to present to you our comments.

The Yakima County Commissioners unanimously support the Forest Service Alternative B with certain modifications. Briefly, we would like to summarize our reasoning.

- 1) We feel that the appetites of the various parties interested in the forested area should have been satiated during the recent wilderness negotiations. We feel it was the best compromise possible as is indicated by the apparent lack of total satisfaction by any individual interest. Whenever a compromise is struck, in this case involving the use of forest land, there has been a taking from status quo. It is our sense that there can be no more give from land available for cutting.
- 2) Perhaps there needs to be an indicator species by which the impact on the animal population can be gauged. But to choose the Spotted Owl, a species by which there is such diverse opinion on its needed habitat, seems rather peculiar. Estimates range from 1,000 acres to 8,600 acres per pair. In addition the credibility of the assumption that it needs

old growth timber is under question. We as Commissioners have taken sworn testimony by the Yakima Indian Nation that certain of its arid lands are the habitat of the Spotted Owl--land which has as its tallest plant growth the sage brush. Further, Spotted Owls are reportedly inhabitants of second growth timber. In addition to land set aside for Spotted Owls, more land would be set aside for the Marten, the 3-Toed Woodpecker and Pileated Woodpecker. The cumulative total of set aside would be much too great an impact on potential timber harvest.

- 3) Considerable doubt has arisen as to the validity of the numbers used and the methodology of the process. So much so that the feelings are that the statistics are skewed in order to validate a pre-determined position. We feel these statistics should be held up to an unbiased evaluation prior to the final adoption.
- 4) The assumption is that reduced cuts increase recreational opportunity. The opposite would appear to be true. Again the forested area dedicated to assure adequate wilderness recreational activity seems to be sufficient. For the balance of the forest recreational users, it would appear that the logging roads increase one's ability to reach a destination in less time. Thus a wider range of both single day and overnight experiences are made available to the increasing pressure of the population. Additionally, by opening a limited number of new roads, it seems the concentration of harvesting would be diminished and more acreage would be available for the same amount of harvest.

Our concerns which would modify or affect Alternative B are

- 1) We are concerned about the 525 miles of trail which are eliminated by Alternative B. Upon inquiry it appears the Forest Service is not sure from where this figure comes. This adds support to 3) above.
- 2) We are also concerned about the reduction of scenic quality on scenic corridors. We would support full retention along these travelways rather than partial retention. At this time it not clear to us just how partial retention would appear.
- 3) Care should also be taken that the final plan does not conflict with the objectives of the Yakima River Basin Enhancement Project now in progress. Under this project, millions of dollars will be spent to increase instream flows for the protection and enhancement of anadromous fish as well as to provide supplemental water supply to meet irrigation needs. With such a large investment of public funds, it is important that spawning habitat for anadromous fish are protected from logging-related damage. Construction of 2,196 miles of new logging roads, coupled with harvesting a quarter million acres of currently undisturbed natural watershed, will be counterproductive to the work of the Yakima River Basin Enhancement Project unless protective measures are used.

Mr. Don Smith

Page 3

- 4) We definitely oppose running roads right up to Wilderness boundaries. There should be a buffer zone.
- 5) It is our feeling that clear-cutting should be limited as much as possible--perhaps used only to deal with diseased timber.
- 6) To reduce the conflict between cutting and trails, we would prefer to see a management policy which would assure that trails which are impacted will be restored and properly marked.
- 7) A great deal of litter is created from logging. Would it be possible that a deposit by the successful bidder be required in order to assure post harvest clean-up? If this is not done satisfactorily, then the deposit could be used to defray the cost of clean-up either by a youth corps or by lawbreakers who are sentenced to community service.

A final note. We suspect that the Spotted Owl habitat issue and the need for accelerated road building are means to address future wilderness creation by interested parties. Our preference is for any wilderness addition to be addressed on its own at an appropriate time.

We greatly appreciate being given the opportunity to comment.

Sincerely,

Graham Tollerison, Chairman

K-346

Office Of The Mayor
City of Seattle

Charles Royer Mayor

October 1, 1986

Don Smith
Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, Washington 98801

Dear Mr. Smith:

The citizens of Seattle have a keen interest in the Wenatchee National Forest, and we are pleased to respond to your Draft Land and Resources Management Plan.

The Wenatchee is a popular destination for Seattleites who help make it one of the most visited forests in the country. The wild and beautiful Wenatchee draws us--whether for hiking, hunting, fishing, rafting, or simply driving the scenic mountain pass highways. Hikes along quiet trails through the roadless back country are cherished outings for many of our citizens. As the Draft Environmental Impact Statement points out, demand for hiking and other primitive types of recreation will continue to increase. We are concerned, however, that the destination will continue to shrink with the proposed plan.

We are particularly concerned about the increase in road construction proposed. These additional roads will reduce trail mileage, increase fishing pressure on fragile mountain lakes, increase sedimentation and eliminate the lower forested trails. Not only do these areas remain open for a longer season, they provide extended hikes, disperse visitors, and often include special features such as groves of giant trees and undisturbed shores of major rivers. More roads will only push the increasing numbers of users into smaller and higher areas, which will only increase impacts to these fragile high mountain lands.

The City also owns land in and near to the forest, (e.g., Entiat Valley and Cedar River). Thus, we are concerned about the effects of management to the adjacent national forest lands.

Don Smith
October 1, 1986
Page two

Seattle residents are also concerned about wildlife habitat in our national forests, particularly old growth forests which have become so scarce. We must make every effort to preserve these ancient and complex expanses of forest and their associated wildlife that find refuge nowhere else. The Lake Creek Valley which drains into the Little Wenatchee River is an example of such an area with huge evergreens towering over a gentle trail along the creek.

Clean water for fish, irrigation and recreation is a critical resource of national forest. The protection of drainage basins in roadless areas will maintain that high water quality. It will also benefit from wild and scenic rivers designation for such rivers as the Wenatchee, Entiat, Naches, and their tributaries. As we resurrect our fisheries, an important recreation and economic resource, we must have undisturbed spawning areas with clean water.

The North Fork of the Entiat River Valley is another example of a valuable but dwindling resource. Here, the significant trail, wildlife, scenic and ecological values indicates a strong need for preservation. Roadless lands in the Chiwawa and Mad River drainages and Mission Creek and Manastash Ridge are also valuable and deserve protection.

Tourism and recreation are our state's fastest growing industries. Sales of books, tours, camping equipment, lodging and roadside services are just some of the activities that benefit the local and regional economy. Leavenworth demonstrates this so beautifully.

Maintaining the scenic beauty that draws people to the forest must be a priority. The shores and mountains that rise above Lake Wenatchee and Lake Chelan must be maintained in all their natural, spectacular beauty. The Chinook Pass and White Pass highways also traverse stunning scenery that needs strong protection.

Significantly, our quality of life is a major attraction for industries seeking new locations. Such economic diversity will complement the contribution of our timber industry as we move into the next century and adapt to new economic patterns.

Don Smith
October 1, 1986
Page three

Protecting the Wenatchee National Forest's outstanding scenic, recreational and wildlife resources is essential for continued growth of our economy, to provide refreshment from the stresses of modern life, and to gain a better understanding and appreciation of our natural heritage. Proper stewardship of these public lands will provide many benefits for us and our children. We urge you to give careful consideration to these values. Alternative F (supported by conservationists, sportsmen, and fishing groups) would better provide that kind of stewardship for these public lands, and we urge you to incorporate many of its features in your final plan.

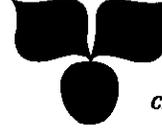

Thank you for the opportunity to comment.

Sincerely,

Charles Royer

Don Smith
Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, WA 98801

Dear Mr. Smith:

With reference to the Wenatchee National Forest Plan prepared by the Forest Service, the Yakima City Council believes that the severity of the economic impact under proposed alternative C warrants full consideration of the report prepared by Brian Long, titled: "Economic Impact Analysis of the United States Forest Service Proposed Alternative C on Chelan, Kittitas and Yakima Counties" (August, 1986).

A majority of the Council believes that the public is entitled to a reconciliation of the data inconsistencies on the timber harvest, and that the IMPLAN I/O model must be updated to 1982 relationships. A supplemental document should then be issued by the Forest Service with opportunity for both public comment and public hearings.

Sincerely,

Henry Beauchamp
Mayor

Wenatchee, WA 98801

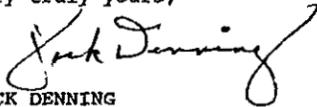

Dear

As Mayor of the City of Roslyn, Washington, I have been instructed by the Council of the City of Roslyn to formally respond to the latest Wenatchee National Forest Plan and in particular to the 10 year timber sale plan contained in one of the Appendixies to the Forest Management Plan. The City of Roslyn objects very strenuously to the 10 year timber sale plan as it pertains to Section 36, Township 21 North, Range 13 East and Sections 6 and 8 of Township 20 North, Range 14 East, Kittitas County, Washington, or more commonly referred to as the Easton Ridge area. As you are aware, the City of Roslyn domestic water originates from Domerie Creek. The Domerie Creek watershed encompasses Easton Ridge and any logging, road building or slash fires would potentially contaminate the Domerie Creek watershed.

The Forest Service in the past has acknowledged in its various plans, including the Alpine Lakes Wilderness Plan, the future pressure that the Forest Service would foresee for maintaining clean water. The theory obviously is that the more the National Forest is used, the more potential the variety of uses has to contaminate clean water. Today is that foreseeable future and the City of Roslyn is complaining now, not in the future (although the City will complain in the future as well). I find it amazing how the federal government through the Environmental Protection Agency and the Clean Water Act can place demands upon municipalities such as the City of Roslyn to maintain high standards for its drinking water yet on the other hand allow the National Forest Service to completely undo what Congress had intended to obviate with the Clean Water Act. Let's work together, not against each other for the preservation of clean water.

I trust that you will record the City of Roslyn's objection to the Wenatchee National Forest Plan and in particular to the 10 year timber sale plan and act thereupon. Should you want any further input please feel free to contact me or any other citizen of the City of Roslyn.

Very truly yours,

JACK DENNING
Mayor

September 24, 1986

Don Smith, Forest Supervisor
Wenatchee National Forest
301 Yakima Street
Wenatchee, WA 98801

Dear Mr. Smith:

Naches is a very small town with its economy almost totally reliant upon forest products and agriculture. The impact on all of us when a few jobs are lost is significant. Any cut in revenue to the schools would hurt severely. There is an ongoing need for construction of school buildings which have been put off due to declining revenue from the depressed lumber industry. Any further cut would be unthinkable.

You seem to have decided on Plan C for your comprehensive plan for the Wenatchee National Forest. I believe this plan would cause severe hardship in this area. We do believe a balance is necessary between forest uses and appreciate the recreational uses of the forest as well as the commercial. Plan C is not in the best interests of any of us.

The Essential Alternative Plan seems to be a reasonable plan that will protect our forests, wildlife and economy and allow for continued recovery in the timber industry. Please consider this plan and I urge you to accept it as your comprehensive plan for the Wenatchee National Forest.

Sincerely,

Mary E. Tenney, Mayor

Don Smith, Forest Supervisor
Wenatchee National Forest
301 Yakima Street
Wenatchee, WA 98801

Dear Mr. Smith:

The recently released Wenatchee National Forest Plan prepared by the Forest Service includes your preferred alternative plan "C" which you admit will eliminate 210 jobs and \$6.6 million in income throughout Yakima, Kittitas and Chelan counties. While it may be the general belief of the Forest Service that this economic impact will be accepted by the communities in the region, the actual losses are significantly greater than you have led the public to believe.

The data used by the Forest Service to make their calculations takes into account a 22% reduction in available harvestable timber and bases the economic impacts on pre-1982 timber industry production and a 1977 IMPLAN I/O model. These base calculations are not realistically translatable to 1986 timber industry practices.

Through the efforts of the Yakima County Development Association and the Forestry Task Force of the Greater Yakima Chamber of Commerce, an independent economic analysis of the impacts of preferred alternative "C" has been conducted. The findings of this analysis indicate an actual job loss of 936 jobs and a loss of \$29.5 million in total income should alternative "C" go into effect. This severe impact is totally unacceptable to the citizens of Central Washington

While we believe a balanced timber harvest is necessary, we favor

03427

Don Smith, Forest Supervisor
September 23, 1986
Page 2

maintaining existing employment opportunities through the harvest and manufacture of forest products. This is essential to economic stability in our communities. Environmental protection can be afforded the forest without negative impacts on employment through the following:

1. Adopt alternative "B" with minor changes.
2. Meet minimum requirements, but do not reduce timber yields until Spotted Owl habitat requirements are established specifically for Wenatchee National Forest environments.
3. Enhance wildlife resources through a selective road management program.
4. Protect the existing trail system and replace trails which are lost due to road development. Disperse trail use concentrations through additional trailheads.
5. Develop the roadless areas within the first two decades to bring those under management.
6. Intensively manage all the suitable general forest to enhance tree replacement and growth

It is the sincere belief of myself and officials from the three-county area, Chelan, Kittitas and Yakima, that the implementation of alternative "B" with these minor changes will allow for continued recovery in the timber industry, recreational opportunities, and environmental protection, all without negatively impacting the regional economy.

It is with a sincere concern for the future of our region that I urge you to accept and implement these recommendations for management of the Wenatchee National Forest.

Sincerely,

John P. Hodkinson, Jr
Mayor

Town of Harrah

P O Box 10
HARRAH, WASHINGTON 98933

September 26, 1986

Don Smith
Wenatchee National Forest
301 Yakima Street
Wenatchee, WA 98801

Dear Mr. Smith

The Town Council of the Town of Harrah, Washington, wishes to express concern regarding the preferred alternative plan "C" on the Wenatchee National Forest Plan. The enactment of plan "C" will have a profound negative effect on the economy of Yakima, Kittitas and Chelan counties. Whether this impact is the 6.6 million dollar loss as your study predicts or the 29.5 million dollar loss that an independent economic analysis predicts, the loss will adversely affect our area due to jobs lost and money allocated from timber sales to school and road funds.

As council members we recognize the importance of planning for the future and we believe that a balanced timber harvest is necessary. We urge you to adopt alternative "B" with a few minor revisions as follows:

1. Meet minimum management requirements, but do not reduce timber yields until Spotted Owl habitat requirements are established specifically for Wenatchee National Forest environments.
2. Enhance wildlife resources through a selective road management program.
3. Protect the existing trail system and replace trails which are lost due to road development. Disperse trail use concentrations through additional trailheads.
4. Develop the roadless areas within the first two decades to bring those under management.
5. Intensively manage all the suitable general forest to enhance tree replacement and growth.

We strongly believe that Spotted Owl requirements need to be specifically established for the Wenatchee National Forest and that both the Spotted Owl habitat requirements and the job requirements of our citizens need to be taken into consideration before setting timber cutting policies. Please give careful consideration to a slightly revised alternative "B" which will offer environmental protection and recreational opportunities without a negative impact on our three county area and on our state.

Sincerely,

Town of Harrah Council

POST OFFICE BOX 151
TOPPENISH WASHINGTON 98948

September 23, 1986

James Torrence, Regional Forester
Wenatchee National Forest
P.O. Box 811
Wenatchee, WA 98801

Dear Mr. Torrence

The Yakima Indian Nation would like to take this opportunity to comment on the fisheries aspects of the Wenatchee National Forest Management Plan. We would like to state at the outset that although it is claimed repeatedly that increases in fish to the forest will largely be due to increased escapements, it is possible to sustain and increase escapement only if high quality fish habitat is provide. Therefore, it is of the utmost concern to the Yakima Nation that the best possible habitat for salmon and steelhead is available on forest lands. We also feel that diminished numbers of fish within the forest is not only due to downstream effects, but also because of environmental perturbations, use as grazing, road building, and timber harvest within the forest itself.

K-354

Roads - Our concerns regarding roads center around increased sediment yield and fish passage. Clearly, the large number of roads proposed to be built will result in a greater number of culverts. Each culvert imposes a risk of failure and an increased maintenance cost. Present surveys on the Naches District show 60% of the culverts present fish passage problems, and these are stated to be on resident fish streams. Are there no anadromous fish in these streams because of poor culverts? In addition, these inventories were not done on the Cle Elum district or in the Wenatchee or Entiat Drainages. We therefore, do not know the status in these areas. These surveys should be completed and funds should be appropriated to correct passage problems, with highest priority given to streams with a potential for producing anadromous fish.

It is stated in the DEIS that road density is 3.75 miles/section (III-96) or 4 miles/section (III-149). There is no discussion of densities within sub-basins. Studies on the Olympic peninsula have shown detrimental levels of sediment entering streams with road densities greater than 3 miles/section. There must be studies done to determine appropriate road densities on the Forest, and this should be done on a sub-basin scale.

It appears that these will be a proliferation of ORV roads on the forest. Is there an inventory of existing roads, and has there been an analysis to determine the impacts of these roads to fish habitat. We would like to see this analysis completed before there is an increase in these activities on the forest.

In certain watersheds (Little Naches/Upper Rattlesnake) there is evidence of high natural levels of mass wasting. Will inventories be done to evaluate

past performances of roads and their association with mass wasting, particularly on a sub-basin level. Because of the increased sediment associated with roads, we would encourage reductions of timber harvest in those watersheds with high natural levels of mass wasting.

Soil - The DEIS states that impacts of sedimentation resulting from timber harvest will be negligible compared to background levels. These levels were based on a model designed for predicting soil erosion on agricultural land. Has there been any calibration to determine if these predictions are valid. As stated above, there needs to be predictions done on a sub-basin scale. Potential cumulative effects are identified on a number of sub-basins. We feel that empirical data should be gathered to better prescribe management actions. Of particular concern are the Little Naches, Manastash Creek, Pyramid Creek, Blowout Creek, Taneum Creek, and Nason Creek. These creeks are all present or potential anadromous fish bearing waters. Without detailed sub-basin evaluation, it is difficult to assess the appropriate management strategy. We also question whether 40% of a watershed in created openings with trees less than 15 feet tall will adequately avoid cumulative effects of increased sediment loading. There is no discussion of the basis for this strategy, or whether this is too much or too little for particular sub-basins. As stated in the Plan the soil survey information for the Yakima County portion of the plan is "terribly out of date and not adequate for project level planning." This is very disconcerting when management plans are being developed for the Yakima River Basin.

Water - We are particularly concerned about the impacts of harvest activities on water yields. Your analysis looks at water yields on a forest wide basis. We feel there must be analysis performed on sub-basins where cumulative impacts have a high likelihood. In addition, we feel that mean annual yield has no real meaning. The concerns are high peak flows, which act to destabilize stream channels, and reductions in summer low flows. Although one approach is to claim that summer low flows will be increased due to reduction in evapotranspiration, there is no discussion of the converse. That is, after tree planting, will there be a greater (than pre-harvest) level of evapotranspiration a short time later. We feel this analysis is crucial for sound management decisions. In addition, as stated above, there is no discussion of why 40% created openings, or 1,000 acres is used as a guideline to reduce impacts. We would also like to see analysis and a monitoring program to examine the effects of rain-on snow events in these areas, and the impacts to fish habitat. Finally, temporary water yield increase (DEIS III-76) as a result of timber harvest can result in unacceptable long term habitat degradation.

Range - While we are dubious about the positive effects of cattle grazing on fisheries habitat, we do not see large scale impacts of grazing on fisheries in the forest at this time. However, we feel that the amount of grazing (AUMS) should be held constant. If there are new grazing allotments, these should be surveyed to determine the impact on the aquatic ecosystem, and

detailed mitigation plans should be devised. We would also like to see an inventory of cattle/fish impacts that exists on the forest today.

Fisheries - We would like to commend you on the detailed discussions of the fisheries impacts of the plan. However, this analysis is based on a distressing lack of detailed data. If the forest is in fact a multi-use land management area, sufficient funds should be provided to adequately survey all resources. We question the resources committed to fisheries habitat management as compared to timber harvest and its associated requirements (roads, administration etc.). There should be an immediate increase in resources committed to habitat inventories, studies of fish populations and distribution etc. It is only in this fashion that sound management decisions can be made.

We feel that the EW-2 designation is by and large a sound management strategy. Some questions are not addressed however. Are there certain slopes too steep for harvest within this area. We would like to suggest that on very steep slopes (70%) that there be no harvest below the first topographic break uplope from the stream. Also, we have some concern that firewood cutting can have deleterious effects successful management in this area. We would like to see that no firewood cutting of live, dead or downed material be allowed within 100 feet of any class I, II or III stream. It is only in this fashion that a recruitment of woody debris can be guaranteed.

We have some questions about the reliability of assumptions regarding smolt habitat capability when no detailed surveys have been done. Additionally, what precisely is the method for defining smolt habitat capability.

We feel that an inventory of forest service related activity that has already impacted fisheries habitat is germane to good management practices. It is possible that this could be accomplished in part from air photos and past records of activities.

We feel that Table III-18 (DEIS III-47) is in error. Smolt Habitat capability for Sockeye in the Yakima River is estimated in your table to be 0. In fact, studies are just beginning to determine the feasibility of fish passage at Lake Cle Elum. If passage is possible there are many miles of good habitat above the Lake, and we would not want the Forest Service to preclude any management options based on underestimations of potential smolt yield. We understand that predictions of smolt yield are in flux in the Yakima Basin at this time, but would like to see a further refinement of this number.

Because of the potential cumulative effects as a result of intermingled ownerships on Forest Service lands, we support the theory of pre-and post harvest monitoring. One question is when will this begin, and what will be the level of involvement. We hope that empirical data will be gathered, rather than through estimations based on theoretical models. We would hope these monitoring programs include inventories of bank stability, incidence of mass wasting sediment yield, presence of woody debris, and water yield, and that these analysis take place at the sub-basin level. In addition, we feel

that there should be analyses of changes in stream temperatures as a function of harvest activity. These should include areas under EW-2 management, as well as analyses of cumulative effects in areas cut prior to implementation of the new plan.

We feel that the standards and guidelines section is lacking in substance. What are the standards to be used to insure that there is adequate woody debris in streams. What stream temperature guidelines will be used? Is there a baseline input of sediment that is acceptable? What are the guidelines for mitigation, or enhancement? What will order priorities for expenditure of K-V or appropriated funds? What is the guideline that will determine that a bridge rather than a culvert will be installed at stream crossings? Questions of this nature should be addressed? We find a very elaborate set of criteria for wilderness areas (which by the very nature of being in a natural state should require few guidelines) and little discussion with regard to fish and wildlife concerns. We hope the final EIS will have a more substantial analysis.

Finally, we would like to see a detailed monitoring plan outlined in the document. Specifically, which sites and what resources will be monitored.

Alternatives - We feel that your representation of alternatives with regard to fisheries impacts is not realistic. Alternative E shows the least changes in sediment yield and water yield, and the greatest number of fish throughout the 5 decades of the scope of planning. In fact, these benefits are accrued solely due to the large amount of appropriated funds, if the modelling of sediment and water yields is accurate. We feel that this is not a realistic alternative. Conversely, we see fisheries benefits in Alternative B due to large expenditures of K-V funds. In essence, this alternative says that you can degrade habitat, but you will then have the money to mitigate the impacts. Again, we feel this is not a viable alternative. In fact, we question the availability of expenditure of K-V funds. Our understanding is that authorization of these expenditures have not been forthcoming. Intensive timber management on the forest predicated on mitigation with K-V funds leave the fisheries resource in an extremely precarious situation. In addition, these funds can only be used for activities within sale boundaries, and as reported in the DEIS, primarily for mitigation in resident fisheries. How then can these funds be used to mitigate for downstream, cumulative impacts? How can they be used to repair existing inadequate culverts? Will there be expenditures for mitigating habitats lost due to construction of the Naches River Road (Highway 410) along the Naches River for example. We hope that a sufficient level of appropriations will be requested to address these concerns.

Because there is so little inventory data collected on the forest, it is difficult to have specific sub-basin requests for management strategies. We therefore, can only offer a generalized strategy that will address our concerns. When additional data is made available, we would be happy to discuss site specific recommendations with you.

03550

We would like to see along all anadromous streams a classification similar to ST-1 that would extend from the upslope limits of the EW-2 to above the first topographic break. This would entail a limited entry with no commercial thinnings. This will decrease road use and construction, and will reduce the amount of the land base that is actively undergoing changes resulting from timber harvest. As additional data becomes available, these streams could then be managed on a more site specific basis. We concur with your alternative C for the American Teanaway, Entiat and Bumping River corridors. We feel that alternative F is most appropriate for the Rattlesnake Creek Drainage. Both the Teaneum and Manastash Creek drains need to be afforded as much protection as possible due to the large amount of private ownership in the Teaneum, and the past intensive harvest activities in the Manastash. Both these creeks are anadromous fish bearing streams.

The Yakima Nation would also like to thank the Wenatchee National Forest for their commitment to meeting the needs of the Yakima people, and we look forward to continued discussions with you in this regard. Please refer to correspondence from the Columbia River Inter-Tribal Fish Commission for additional concerns regarding fish and wildlife resources on the Wenatchee Forest. If you have additional questions about our comments, please contact Larry Wasserman of my staff at 865-5121, ext. 672.

Portland, OR 97208

RECEIVED
OCT 2 1986
PLAN/PD&B

Dear Mr. Torrence,

The Columbia River Inter-Tribal Fish Commission appreciates this opportunity to comment on the Draft Environmental Impact Statement (DEIS) and the proposed Wenatchee National Forest Plan. The Commission is composed of the Fish and Wildlife Committees of the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes and Bands of the Yakima Indian Nation, the Confederated Tribes of the Warm Springs Reservation of Oregon, and the Nez Perce Tribe. These four tribes have rights reserved by treaty to take fish that pass their usual and accustomed fishing places. Among these fish are the anadromous species that originate in the Wenatchee National Forest.

The Nature of the Treaty Right

The tribes' right to take fish that pass their usual and accustomed places is a right confirmed by numerous court decisions. See e.g. Sohappy v. Smith, 302 F.Supp. 899 (D. Or. 1969), aff'd, United States v. Oregon, 529 F.2d. 570 (9th Cir. 1976); Washington v. Washington State Commercial Passenger Fishing Vessel Ass'n, 443 U.S. 658 (1979) (Passenger Fishing Vessel). In addition to binding state governments, See Passenger Fishing Vessel 443 U.S. at 682 and n.25, the treaties are also binding on private citizens, See e.g. United States v. Winans, 198 U.S. 371 (1905), and of course the federal government. Passenger Fishing Vessel, 443 U.S. at 682; See also Confederated Tribes of the Umatilla Reservation v. Alexander, 440 F. Supp. 553 (D. Or. 1977). Absent specific authorization by Congress, Indian treaty rights cannot be abrogated. Id., citing Mencinnee Tribe v. United States, 391 U.S. 404, 413 (1968).

In Passenger Fishing Vessel, the Court painstakingly examined the circumstances surrounding the negotiation of the treaties in an attempt to divine the parties' long-term intentions. The Supreme Court emphasized that Governor Stevens invited the Tribes to rely on the United States' good faith

efforts to protect their right to a fisheries livelihood. Stevens specifically told the tribes: "This paper [the treaty] secures your fish." Id. at 667 n.11. During the treaty negotiations, "the Governor's promises that the treaties would protect that source of food and commerce were crucial in obtaining the Indians' assent." Id. at 676 (emphasis added). As the Supreme Court stressed:

It is absolutely clear, as Governor Stevens himself said, that neither he nor the Indians intended that the latter "should be excluded from their ancient fisheries," . . . and it is accordingly inconceivable that either party deliberately agreed to authorize future settlers to crowd the Indians out of any meaningful use of their accustomed places to fish.

Id. The Supreme Court also mentioned that the treaty guaranty of "the right of taking fish" was meaningful only if fish were available for the taking. Id. at 678 (emphasis added).

The 130 years since the treaties were signed have witnessed a truly startling number of methods by which the quantity of fish available for the taking could be reduced -- if not decimated. The courts have responded to these threats to the treaty right by declaring a policy that the treaty right cannot be defeated by technology or other methods not anticipated by the treaty signatories. For example, in United States v. Winans, 198 U.S. 371 (1905), the defendant constructed a fish wheel (a device capable of destroying an entire run of fish) and excluded the Indians from one of their usual and accustomed fishing places. Commenting on the effects of improved fishing devices, the Court noted that:

wheel fishing is one of the civilized man's methods, as legitimate as the substitution of the modern harvester for the ancient sickle and flail . . . It needs no argument to show that the superiority of a combined harvester over the ancient sickle neither increased nor decreased rights to the use of land held in common. In the actual taking of fish white men may not be confined to a spear or crude net, but it does not follow that they may construct and use a device which gives them exclusive possession of the fishing places, as it is admitted a fish wheel does.

Id. at 382. Thus, although improved technology may be brought to bear on the fishery, that technology cannot be allowed to imperil the rights secured to the parties to the treaty.

This result was reaffirmed by the Supreme Court in Passenger Fishing Vessel. There the Court declared that "[n]on-treaty fishermen may not rely on property law concepts, devices such as the fish wheel, license fees, or general regulations to deprive the Indians of a fair share of the relevant runs of anadromous fish in the case area." Passenger Fishing Vessel, 443 U.S. at

684. The Court's intent is clear: absent specific treaty abrogation legislation from Congress, (Menominee Tribe v. United States, 391 U.S. 404, 413 (1968)), no one may use any method to deprive treaty fishermen of their fair share of the anadromous fish.

Federal Duty to Protect Subject Matter of Treaties

In addition to their obligation to not destroy Indian treaty rights without specific Congressional action, federal agencies must use their authority to safeguard that which is the subject matter of federal treaties. In Kittitas Reclamation District v. Sunnyside Valley Irrigation District, 763 F.2d 1032 (9th Cir. 1985), the Ninth Circuit affirmed a district court order to operate a Yakima water project in a manner that would preserve spring chinook salmon redds. Federal project operators had originally sought to reduce water releases in order to store water for the next irrigation season. The proposed flow reductions would have left the redds high and dry. Testimony at the district court hearing indicated that the proposed water storage would be possible if twelve redds were transplanted or if berms were constructed. Id. at 1035. However, the district court judge was "unsure of the effect of these measures, so he continued the watermaster's authority to release water as necessary." Id. Expressly declining to decide the scope of the Yakima Indian Nation's treaty fishing rights, Id. at n.5, the Ninth Circuit found that the district court judge had fashioned a reasonable remedy. Id.

The message in Kittitas is clear. Federal agencies are obligated to exercise their authorities in a manner that will protect -- not degrade -- the habitat needed to support anadromous fish. In addition, when addressing anadromous fish habitat needs, various measures may be utilized, but the final choice turns not on traditional notions of agency expertise, but on the biological needs of the fish.

Magnitude of Fisheries Reserved by Treaty

The Forest Service's duty to protect and enhance anadromous fish habitat does not cease once a fish run becomes viable. The tribes did not reserve a right to take a few fish from a meager run struggling for survival. Some might argue that the Columbia River treaty tribes reserved the right to continue harvesting that number of fish that they had traditionally harvested. Obviously, that harvest level is not yet possible given the contemporary depleted fisheries. The Supreme Court has held that both Indian and non-Indian fishermen possess a right, "secured by treaty, to take a fair share of the available fish." Passenger

Fishing Vessel, 443 U.S. at 684-85. The Court determined that Indian harvest allocation should not exceed 50% of the harvestable fish. Id. at 685-86. The Court then declared:

It bears repeating, however, that the 50% figure imposes a maximum but not a minimum allocation . . . [T]he central principle here must be that Indian treaty rights to a natural resource that once was thoroughly exclusively exploited by the Indians secures so much as, but no more than, is necessary to provide the Indians with a livelihood -- that is to say, a moderate living. Accordingly, while the maximum possible allocation to the Indians is fixed at 50%, the minimum is not; the latter will, upon proper submissions to the district court, be modified in response to changing circumstances. Id. at 686-87.

Perhaps the reason why this "moderate living standard" unearthed by the Supreme Court has not proven to be a truly thorny problem in Pacific Northwest fisheries management is because no one can reasonably contend that the Indians' harvest presently yields a moderate living. This fact was implicitly acknowledged by the Supreme Court in Passenger Fishing Vessel when it stated that the 50% ceiling on the Indians' harvest allocation was necessary "to prevent their needs from exhausting the entire resource and thereby frustrating the treaty right of 'all [other] citizens of the territory.'" Id. at 686.

Regardless of what the term "moderate living standard" means, it will eventually be defined by the judiciary -- not a federal agency. See Id. at 687. As discussed earlier, the Ninth Circuit has already determined that federal agencies must refrain from taking actions that will reduce the number of fish in a depleted run. See Kittitas, 763 F.2d at 1035. Nor does this duty cease when an anadromous fish run manages to increase its numbers beyond the dangerous level of minimum viability. In United States v. Adair, 723 F.2d 1394 (9th Cir. 1984), the Ninth Circuit stated that:

Implicit in this "moderate living" standard is the conclusion that Indian tribes are not generally entitled to the same level of exclusive use and exploitation of a natural resource that they enjoyed at the time that they entered into the treaty reserving their interest in the resource, unless, of course, no lesser level will supply them with a moderate living. Id. at 1415 (emphasis added).

Here the Ninth Circuit has indicated that the Klamaths must be allowed to achieve their "moderate living." No one knows what that is. The court explicitly stated the possibility that the "moderate living standard" may only be achieved by allowing the tribe to enjoy the "same level of exclusive use and exploitation" it had at the time the treaty was concluded. Id. The purport of this holding is clear. Federal agencies owe a duty to refrain

from activities that will interfere with the fulfillment of treaty rights. Moreover, this duty cannot be performed by engaging in an "accommodation" or "balancing" process between Indian treaty rights and a competing economic interest such as timber harvest. Any such "accommodation" reached by the Forest Service would amount to a de facto abrogation of Indian treaty rights. In the context of forest management, unless the Forest Service can demonstrate that the tribes' treaty rights are presently being fulfilled, it cannot justify approving activities in the forests that will cause further degradation of anadromous fish habitat.

The National Forest Management Act Mandates Coordination

The Forest Service is only one of the many entities involved in the complex interactions that have caused the diminution of anadromous fish runs to their present state. Columbia River hydroelectric development and other downstream problems have done grievous harm to the basin's fish runs. While the Forest Service can rightfully blame downstream problems for much of the harm inflicted on anadromous fish, such blame does not obviate the Forest Service's responsibility to protect anadromous fish and the need for all parties with management authority that affects these fish to work together to improve the fishery resource.

In dealing with anadromous fish, the Forest Service must look beyond the boundaries of a given national forest. Columbia River stocks of anadromous fish migrate as far inland as Lake Osoyoos and as far north as Alaska. As the Pacific Northwest has come to realize, the anadromous fish runs can only be restored if state, federal, and tribal land, water, and wildlife managers adopt a coordinated "gravel-to-gravel" management approach to this valuable and mobile renewable resource.

This approach is reflected by the Northwest Power Planning Council's Columbia River Basin Fish and Wildlife Program. The Fish and Wildlife Program, mandated by the Pacific Northwest Electric Power Planning and Conservation Act, 16 U.S.C. Section 839b (1982), encompasses the Columbia River and its tributaries and will be financed by Pacific Northwest ratepayers. This comprehensive protection, mitigation, and enhancement effort does not appear to be integrated into the DEIS or proposed plan. Nor were the increased fish returns made possible by the recently concluded United States/Canada Salmon Interception Treaty, See 16 U.S.C. Section 8396 (1985 Supp.), mentioned in either document.

These efforts, along with the Salmon and Steelhead Enhancement Act, have changed the complexion of fisheries management in the Columbia Basin. The success of both the Salmon Interception Treaty and the Fish and Wildlife Program turn upon maximizing utilization of the anadromous fish habitat in Columbia River tributaries. A large percentage of these tributaries run

through national forests. The Forest Service must acknowledge its responsibilities to act in concert with these policies. The Forest Service cannot make a reasoned decision with respect to anadromous fish habitat if it does not factor these activities into its decision-making process. The Pacific Northwest cannot afford to spend money enhancing fisheries that are simultaneously being degraded by timber harvest, road-building, and grazing.

Forest Service coordination with Pacific Northwest fisheries enhancement activities is not only sound policy; it is also required by law. Forest Service regulations declare that a review of state, federal, and tribal planning and land use activities shall be included in the forest plan EIS. See 36 C.F.R. § 219.7 (a)-(c) (1984). In addition, the regulations provide that this review shall consider the objectives of federal, state, local, and tribal governments, inter-related impacts of these plans, and a decision by the Forest Service on how each forest plan shall address these inter-related impacts. Id. at (c)(1)-(4). Among the objectives of federal, state and tribal governments are the fish production plans currently being formulated under the auspices of United States v. Oregon, the Fish and Wildlife Program, and the Salmon Interception Treaty.

The Wenatchee National Forest states that its fisheries management proposals are compatible with the Columbia Basin Fish and Wildlife Program and the Yakima River Basin Water Enhancement Project because these plans and all DEIS alternatives call for habitat improvement. See DEIS at IV-40. At best, this is a gross over-simplification. Not all habitat is equal. Do the locations of planned habitat improvements for these plans and alternatives correspond? Does the Forest anticipate timber, range, or mining management activities that will nullify any of these enhancement projects? How is a forest management activity that is inconsistent with a Fish and Wildlife Program measure consistent with the tribes' treaty rights?

Statements such as the following will not fulfill the Forest Service's duty to consider tribal land use objectives and determine how the forest plan inter-relates with these objectives:

Though there is considerable competition for the water produced in any alternative, there is no significant conflict between the effects of the alternatives and others' plans and policies for the water resource. Principal competitors for water produced on the Forest include irrigation interests, small hydroelectric interests, and those interested in maintaining adequate fish habitat.

DEIS at IV-72. There are few issues that have spawned more conflict than disputes over water allocation in the Yakima Basin. The amount, quality, and timing of water flow in the Yakima Basin are factors whose importance cannot be over-emphasized. Forest management will affect these characteristics and thus much more

detailed coordination is necessary before the Forest Service satisfies its NFMA duties, treaty-imposed duties, and its trust responsibility to the Yakima Indian Nation.

The idea that proper fishery management requires coordination of harvest, passage, and production needs has been around for a number of years. It is also an integral aspect of the Northwest Power Planning Council's efforts to coordinate restoration of Columbia basin fisheries to the extent affected by hydroelectric power production. See e.g. Northwest Power Planning Council, Salmon And Steelhead Planning, Staff Issue Paper (June 3, 1986):

A gamut of potential problems may result from uncoordinated actions. Fish production investments may be in conflict. Power system operations may diminish production or offset increases in production. Harvest practices could prevent escapement in adequate numbers to ensure sustained increases in yield. The mixed-stock harvest could undermine passage actions designed to protect or enhance certain stocks of fish. Harvest and power needs may not be sufficiently defined to guide production efforts. Production decisions may be made without full regard to harvest needs and to power system constraints with respect to passage. Land and water management actions may undermine fish production investments.

When actions are taken in the absence of a system perspective, there also may be too little recognition of the spectrum of choices among production, passage and harvest actions. Actions may be taken without consideration of the full range of alternative means to achieve objectives. Actions may be taken with inadequate analysis of their likely effectiveness. As a result, there is no assurance that a given action achieves sound biological objectives at the minimum economic cost.

Moreover, in the absence of a system perspective, monitoring and evaluation of actions may be uncoordinated, lacking, short-term, sporadic, or narrow in focus.

Id. at 8. In addition to improving the quality of resource management, coordination often results in lower costs. In this time of fiscal austerity, the Forest Service would do well to explore all the possibilities provided by increased coordination.

Statements in the DEIS indicate that the WNF feels that coordination will fulfill treaty rights:

On the Forest, management for habitat stability and stream integrity, specific fish habitat improvement

projects, and ongoing research by the Yakima Indian Nation regarding management of chinook salmon in the Yakima River system will all contribute to enhancement of fisheries habitat. Continuing coordination with the Washington State Departments of Game and Fisheries, the Yakima Indian Nation, and the U.S. Fish and Wildlife Service, will also contribute substantially to meeting the responsibilities defined by the Yakima Indian Treaty.

DEIS at III-46. See also Id. at II-136 ("With continued coordination between the Forest Service and all the other groups and agencies which affect fisheries production and potential, long-term compliance with the Treaty is anticipated."). As far as these statements go, they are correct. (What does long-term compliance mean? Does that mean the Forest anticipates short-term non-compliance?) The tribes' treaty rights probably will not be fulfilled in the absence of coordination. However, what is the standard or goal that this coordination is designed to achieve? The appropriate legal standards are delineated at the beginning of these comments.

Anadromous Fish Assessment

As a consequence of its federal mandate to protect, mitigate, and enhance fish and wildlife while assuring the Pacific Northwest an adequate and economical power supply, the Northwest Power Planning Council is currently estimating the location and extent of anadromous fish in the Columbia Basin. This assessment will:

estimate the resource value by characterizing the productivity of each stream reach. Productivity is defined to be comprised of three factors: smolt production, migration use and upstream geography which may, through sedimentation, affect downstream anadromous fish areas. This study will quantify the smolt productivity of each stream reach. Migration will be accounted for by including in any estimate of smolt production for an individual stream reach upstream productivity as well, i.e., the productivity will accumulate as one moves down a stream. Stream reaches upstream of anadromous fish areas which have the potential to adversely affect downstream use will be identified quantitatively.

See Northwest Power Planning Council, Proposed Work Plan Pacific Northwest Hydro Assessment Study (August 1, 1984) at 3. The results of this study will provide the most current and comprehensive examination of Columbia Basin anadromous fish production capability available. This study will be used to identify areas and stream reaches that, due to their value to

fish, should be protected from hydroelectric development. It would be wasteful and expensive indeed to invest money in habitat enhancement and protection only to have those efforts smothered by sediment generated by logging and roadbuilding. The Forest Service and anadromous fish managers from federal, state, and tribal governments should coordinate to make sure that the information generated by this study will foster the most judicious resource utilization possible.

Cumulative Impacts

There are 17 national forests in the Columbia basin that produce anadromous fish. These are: the Clearwater, Nezperce, Bitterroot, Boise, Challis, Payette, Salmon, Sawtooth, Umatilla, Wallowa-Whitman, Mount Hood, Malheur, Ochoco, Gifford Pinchot, Okanogan, Willamette, and Wenatchee. All of them are going through the forest planning process. Approximately 50 to 70% of all remaining anadromous fish habitat is contained in these forests. Events on these forests will have a profound impact on the anadromous fish resource that is vital to the welfare and existence of the four treaty tribes.

Unfortunately, the Forest Service does not seem to realize that each forest is an important cog in the machine that will either revive the fish runs or slowly log, road, graze, or mine them into oblivion. To adequately assess the environmental impacts of its actions as required by NEPA, the Forest Service must study and disclose the cumulative impacts of all 17 forest plans listed above on the Columbia River anadromous fish runs and the four Columbia River treaty tribes. It is simply not adequate for each forest to merely look at the impacts of its activities within the borders of the forest or in the surrounding communities and counties. Nor is it adequate for the Forest Service to baldly assert that it has assessed cumulative impacts while offering absolutely no evidence that it has made any such consideration. Fish production precluded by activities within each forest and in conjunction with other forests affects not only surrounding communities, but also downstream Indian tribes and other fishers both inriver and in the ocean.

Adequate assessment of cumulative impacts requires a certain management worldview. It requires that managers of land, water, or fish realize that even though they may only have management authority over a relatively small aspect of the anadromous fish lifecycle, their management decisions may have a decisive impact on other fishery management decisions or the fishery resource itself. This is by no means a revolutionary concept. In fact, the Forest Service avails itself of this management approach every time it asserts that the reason that basin fish production is not any higher is because of downstream passage mortality and harvest management. The Forest Service is correct when it states that harvest and passage considerations are important to the overall health of the Columbia basin anadromous fishery.

However, fish production, both natural and hatchery, are also equally important. The Forest Service is directly responsible for natural fish production occurring on national forest lands. Pointing accusatory fingers at other entities does not relieve the Forest Service of its duty to ensure that its management will not adversely affect already depleted naturally producing stocks.

There are many who consider the need to provide for increased natural fish production to be a major constraint on anadromous fish harvest regimes. The tribes have forgone harvest of fish, to which they are legally entitled, for the purpose of providing increased escapement of naturally spawning adults. Despite these efforts, and despite the increasing numbers of returning adults (many of which are hatchery fish), the tribes are under pressure to further forego harvest opportunities. Forest management that will cause reduction in natural fish production will further exacerbate this situation. Reductions in natural fish production directly conflict with the tribes' treaty rights.

The Forest Service has often informed CRITFC and tribal staff that the Forest Service is only responsible for supplying smolt habitat capability and that there is far more capable habitat than there are smolts. The Forest Service's responsibilities include more than merely furnishing a given amount of habitat. The Forest Service must identify that which is being utilized by fish and, to the extent it can, that which will be utilized through either United States v. Oregon or Fish and Wildlife Program enhancement measures.

By defining its responsibilities solely in terms of smolt habitat capability, the Forest Service attempts to dodge responsibility for existing fish production on national forest lands. Stated differently, by looking only at habitat capability, the Forest Service does not distinguish between habitat that is currently producing fish and that which currently is not. This distinction is crucial because habitat is not fungible. One of the most well-known traits of anadromous fish is that they instinctively return to the stream in which they were born. They do not automatically return to any stream that might happen to be available. Thus, given the depleted levels of many of the naturally spawning anadromous stocks, forest management that fails to protect currently utilized habitat may well result in the destruction of naturally producing stocks despite the great advances being made in juvenile passage and harvest controls. Moreover, because the Forest Service is not protecting currently utilized habitat, destruction of naturally-producing stocks could occur even though the forest may actually be increasing its available "smolt capable" habitat! See e.g. DEIS at IV-137 ("Although every alternative would maintain and enhance the resident and anadromous fish habitat on the Forest, there would be differences in the potential pounds of anadromous fish that are available for sport and commercial harvest.") That is why bland reassurances that fish habitat will be maintained or increased fail to satisfy fishery managers.

A symptom of the WNF's failure to protect naturally-producing stocks is its failure to designate sockeye as a management indicator species. Wenatchee River sockeye are not currently supplemented by hatcheries. In addition, the habitat needs of sockeye are significantly different than those of either chinook or steelhead. Given the lack of hatchery supplementation, sockeye would be a particularly appropriate indicator of the effects of forest management on fish habitat.

It is commendable that the Wenatchee National Forest has attempted to evaluate the cumulative effects of its management activities on anadromous fish. See e.g. DEIS at III-49-54. Unfortunately, there is some important information that was not provided in the DEIS. For example, at no point is the term "cumulative effects" defined. Instead, the DEIS declares that there are three types of human-induced cumulative effects on fish (water quality, stream and streamside habitat integrity, and man-made migration obstacles). DEIS at III-49. What about the effects of forest management on the gene pool of the stocks originating in the forest? Stated differently, does forest management, either on its own or in coordination with other entities, identify local stocks and protect them?

How does production of anadromous fish on the forest interact with downstream harvest? Are fish originating from the WNF subject to a mixed-stock fishery? If so, how will forest management affect that mixed-stock fishery?

It is good that the Forest has chosen a geographic scope for its cumulative effects examination that is commensurate with the migratory range of anadromous fish. However, it is unclear how far "downstream of the forest boundary" the Forest will look. Some Wenatchee National Forest fish are harvested in the ocean. What percentage? Will there be a synergistic effect between ocean harvest and forest management that might constrain Columbia River mainstem fisheries on either steelhead, sockeye, or chinook?

The DEIS states that it has determined "whether there has been, is, or may be in the future a cumulative effect of man's activity" on the four major Forest basins (Chelan, Entiat, Wenatchee, and Yakima). DEIS at III-51. Once again, how was this determined? Forest Service staff at both the forest and regional level have informed CRITFC staff on numerous occasions that cumulative effects studies of the breadth described above are either difficult or impossible to do. Of course CRITFC is gratified that the WNF has chosen to do these legally-required studies, but we are understandably curious about the method used.

The WNF has presented some of its cumulative effects information in the Table III-21 matrix. There it matches the four major WNF drainages with characteristics such as stream habitat integrity and man-made obstruction obstacles. Within these major characteristics are sub-categories such as

downstream effects, WNF only effects, and intermingled ownership effects. In many cases, the table states that there is no known cumulative effect, but at no time does the DEIS state how this determination was made.

In describing situations on or below the four drainages where there may or may not be cumulative effects, the DEIS makes extensive use of the term "significant." See e.g. DEIS at III-51-54. However, no definition of what the WNF considers to be "significant" is provided. Given the complete lack of information as to how the cumulative effects analysis was conducted and the absence of any definitions of terms, it is difficult to provide constructive criticism of the WNF's assessment of cumulative effects.

In its discussion of cumulative effects on the Wenatchee watershed, the DEIS states that:

[s]ome of the logging activities [on non-Forest Service land], although they comply with the State of Washington's Forest Practices Rules and Regulations, may result in long-term losses of habitat production by influencing stream habitat integrity. The primary contributing factor to this loss will be in the quality of streamside cover (and the nutrients it produces) and in long-term inputs of large woody debris.

DEIS at III-51-52. (This statement reinforces what many fish, wildlife, and watershed advocates have been thinking for years. The basis for this statement should be disclosed. No doubt the Washington Department of Natural Resources and the Department of Ecology will be similarly interested.) Is it just the Wenatchee watershed which will suffer from inadequate state forest practices rules? What about the intermingled ownership areas in the upper Yakima basin? How much large woody debris is actually needed?

Shortly thereafter, the DEIS states that the effects of future logging in riparian zones by non-Forest Service entities is unknown. In addition, these intermingled lands should be "monitored and forecasted on a site-specific basis when formulating future Forest Service project plans. In subbasins where a cumulative effect could result in a significant change in fisheries habitat potential, Forest Service activities may need to be altered and/or mitigated." DEIS at III-52. What is a significant change in fisheries habitat potential? Shouldn't the answer to this question depend on the stock(s) that may be affected? Are these fish subject to the treaty rights of the Columbia River treaty tribes? Are these fish involved in the United States/Canada Salmon Interception Treaty? Will proposed management nullify enhancement resulting from the expenditure of Columbia Basin Fish and Wildlife Program funds? These are just some of the questions the Forest Service must address to determine whether there is "significant" harm to fish habitat.

On the Yakima system, the DEIS notes that stream habitat integrity has been affected in several drainages, but although "[t]hese changes in some cases appear to be individually significant...the overall effect on anadromous and resident fish in the Yakima Basin is probably not great." DEIS at III-52. One paragraph later, the DEIS states: "No inventory of stream habitat or streamside habitat integrity has been completed for the streams of the Yakima Basin, so the net significance of forest management is unknown. However, basin-wide, it is not thought that Forest Service activities have had significant effects on anadromous and resident fisheries habitat potential." *Id.* The lack of any definition of the term "significant" or "individually significant" vis a vis "overall significance" makes the discussion of cumulative effects in the DEIS virtually meaningless.

The DEIS states that intermingled lands in the upper Yakima system in the Cle Elum District have huge blocks of clearcuts and that many riparian areas have been subjected to unrestricted timber harvest. *Id.* It also states that these actions may have resulted in cumulative effects, but that these effects can only be measured by pre-harvest and post-harvest measurements. *Id.* The reason that cumulative effects are a concern is that their existence, if not taken into account, can frustrate achievement of environmental goals. The Forest Service is obligated to gather the information necessary to develop responsible estimates of cumulative effects so that a decision-maker will be able to take the action needed to achieve a given environmental goal. It is a result-driven process. In the absence of this information, the Forest Service must not undertake actions likely to cause additional cumulative effects. Unless the Forest Service generates the information needed to assess cumulative effects, it will be unable to either identify the environmental consequences of its action or achieve its fish habitat goals. The Forest Service's failure to gather that data needed to identify the impacts of its activities must not be used as an excuse for maintaining those same activities.

The Forest Service's ability to identify and counteract detrimental cumulative effects is severely hampered by its lack of inventory data. The Wenatchee National Forest's lack of data is candidly acknowledged throughout the discussion of cumulative effects and in its proposed plan at page II-76. It is essential that the Forest collect the data necessary to make the decisions necessary to provide for both fish and other forest resources. See 36 C.F.R. Section 219.12 (d). The tribes' treaties provide independent sources of federal authority for generation and compilation of the data the Forest Service needs to ensure that vital spawning and rearing areas are identified and protected. To fulfill the tribes' treaties, greater fish production is required. The burden is on the Forest Service to ensure that its management activities will not further diminish the basin's fish production. The first step towards fulfilling this duty is to generate the information needed to show that its activities will not further hinder production. Since fish live

in drainages and different drainages support differing levels of fish, drainage-specific information is needed.

The Wenatchee National Forest's reliance on the smolt habitat capability approach tends to conceal cumulative effects on fish. The DEIS recognizes this when it states: "At some point, if the habitat becomes fully seeded with anadromous fish, then there may be, at that time, a net significant cumulative effect of Forest management. This should become apparent in future Forest planning periods." DEIS at III-53. The Forest Service claims that it is only a habitat manager and cannot be responsible for actual populations of anadromous fish. Yet here, when it is convenient, the Forest Service chooses to recognize a cumulative effect not when it harms the habitat, but only when it might adversely affect an existing population. As recent fish escapements demonstrate, that point in time when national forest habitat will be fully seeded is coming far more quickly than the DEIS indicates. The ultimate health of Columbia basin fisheries lies in full utilization of remaining habitat -- much of which lies on national forest lands.

Mitigation

The Forest Service has often relied upon mitigation in the hope that mitigation will compensate for the damage inflicted on fish habitat by timber harvest. However:

Mitigation of fish habitat losses is often presented as a panacea and substitute for maintenance of habitat quality. The concept of "fisheries mitigation" is more myth than substance. It seldom materializes and when it does, it only partially compensates for substantial losses. There is no history of fisheries budgets sufficient to mitigate substantial losses of quality habitat. Recent and projected budget trends indicate a status quo situation.

See Espinosa, Background Paper Fisheries Resources Analysis of The Management Situation Clearwater National Forest (undated) at 56-57 (emphasis in text). The Commission is unfortunately acutely aware of the vagaries and inadequacies of fisheries mitigation. Thus, we are extremely skeptical of vague promises of best management practices, implementation of standards and guidelines, and reliance on enhancement to mitigate management impacts on fish habitat.

Given the importance of the anadromous fish resource, very little reliance should be placed on mitigation measures that do not have a proven record of effectiveness. The Forest Service must be careful to not ask more of a mitigation technique than it can give. New or untested mitigation techniques should be thoroughly evaluated before being widely used and relied on. Monitoring should be vigilant, stringent, and should include all

entities that are involved in the management of anadromous fish. Finally, mitigation methods should be chosen on the basis of the protection they will provide the fishery resource, not how much they will affect the cost/benefit analysis of commodity resources such as timber, range, and mineral extraction. See e.g. Pacific Power & Light Co., Opinion No. 381-A, 30 F.P.C. 499 (1963), aff'd in part, rev'd in part on other grounds, 333 F. 2d 689 (9th Cir. 1964), cert. denied, 379 U.S. 969 (1965) (where it is declared that it is the policy of other federal agencies to require complete recompense for fisheries damage.) The DEIS should be revised to include analyses of known mitigation techniques. These analyses should include evaluations of effectiveness, standards for application, and any other information that might be of aid in deciding whether a given mitigation technique is appropriate. Is reliance on habitat enhancement as mitigation appropriate in the face of the current federal budget crunch? The Commission will be happy to contribute its expertise towards evaluating the use of various mitigation methods on a case-by-case basis.

The DEIS lists the EW-2 Riparian Protection Zone Prescription as being the primary fisheries resource mitigation device. It states that the primary objective of this prescription is to maintain optimum riparian habitat for fish and wildlife and to protect wetlands. DEIS at IV-40. However, this prescription allows both shelterwood and clearcuts in the riparian zone. How does timber management in the riparian zone create better fish habitat than just leaving the area alone? How does increasing sediment delivery to the stream and decreasing the availability of large organic debris benefit fish habitat? Although it is possible that a slight temperature increase may increase juvenile growth rates, what is the cumulative effect of these forest-wide temperature increases? How are downstream waters affected? Are there existing or potential temperature problems downstream that will be exacerbated by the EW-2 prescription? What sediment thresholds is the WNF using? How much large organic debris is needed to provide optimum habitat conditions? Alleging that even-age management in the riparian zone will provide optimum fish and wildlife habitat hardly differs from alleging that no timber harvest in the riparian zone will maximize timber production.

Anadromous Fish Minimum Management Requirements

After combing the DEIS, the proposed plan, and the appendices, we have been unable to find the MMR for anadromous fish. It is our understanding that the NFMA regulations require each forest to delineate MMRs for fish and wildlife. 36 C.F.R. Section 219.27. We are aware that Region VI has issued regional guidelines declaring that state implementation of state forest practices act requirements, developed pursuant to the federal Clean Water Act, are suitable for use as the anadromous fish MMR. (However, given the WNF's view that state forest practices rules

permit activities causing long-term losses of habitat production, this approach is not appropriate. See DEIS at III-51-52) The CRITFC has a thorough critique of this approach and we will be happy to submit it to the Wenatchee National Forest if that is the approach the Forest has adopted. Unfortunately, we have not found any statement in the planning and NEPA documents stating that the Forest has done this. We wish to reserve the right to submit comments on the WNF's choice of anadromous fish MMR.

Trust Responsibility

The trust responsibility is that special relationship between the United States and Indian tribes that originated in Cherokee Nation v. Georgia, 30 U.S.(5 Pet.) 1 (1831) where the Supreme Court described Indian tribes as "domestic dependent nations" and declared that "their relation to the United States resembles that of a ward to his guardian." Id. at 17. This relationship is part of the very fabric of federal Indian law and it imposes stringent fiduciary standards of conduct on federal agencies in their dealings with Indian tribes. See United States v. Creek Nation, 295 U.S. 103 (1935). See also Northern Cheyenne Tribe v. Hodel, Civ. No. 82-116-BLG (D. Mont. May 28, 1985) at 23.

In Northern Cheyenne Tribe, the court declared that "a federal agency's trust obligation to a tribe extends to actions it takes off a reservation that uniquely impact tribal members or property on a reservation." Id. at 27. In an attempt to save its coal leasing EIS from invalidation, the Secretary of the Interior alleged that there was no specific statute or treaty that required the Department to consider the impacts of coal leasing on the tribe as an entity. Id. The Secretary also alleged that his decision to lease the coal was in the "national interest" and "vital to the nation's energy future." Id. at 29. The court declared that:

The Secretary's conflicting responsibilities and federal actions taken in the "national interest," however, do not relieve him of his trust obligations. To the contrary, identifying and fulfilling the trust responsibility is even more important in situations such as the present case where an agency's conflicting goals and responsibilities combined with political pressure asserted by non-Indians can lead federal agencies to compromise or ignore Indian rights.

Id. at 29-30 (citations omitted). Similarly, the Forest Service must not allow its obligations to the Columbia River treaty tribes to become lost in its concern for the local citizenry. It must accord the treaty right special consideration and scrupulous safeguards. As detailed in the earlier legal analysis, the treaties impose substantive, not just procedural, obligations on the Forest Service. These obligations are not fulfilled by

actions which sanction degradation of fish habitat needed to re-build the Columbia River runs.

Sales Below Cost

Over the years, fish and wildlife concerns have often been subordinated to the needs of allegedly more economically valuable, but environmentally damaging commodities such as timber harvest, irrigated agriculture, grazing, and hydroelectric power production. Thus, it is not without some ironic amusement that the Commission observes the current controversy over unprofitable timber sales. Those who have advocated resource decisionmaking primarily on the basis of short-term economic gain suddenly find themselves "hoisted on their own petard." Perhaps this role reversal will convince all those involved in natural resource decisionmaking that cost/benefit analysis is at best an "unfaithful lover" and that resource decisions are best grounded on other bases.

The Commission is not automatically opposed to "sales below cost" per se. What concerns us is that the DEIS contains no assurance that any of the timber sales proposed for the next 50 years will actually recover its real costs. The NFMA regulations require that the Forest Service "shall compare the direct costs of growing and harvesting trees, including capital expenditures required for timber production, to the anticipated receipts to the government...." See 36 C.F.R. Section 219.14(b) (1984). "Direct costs" are defined to "include the anticipated investments, maintenance, operating, management, and planning costs attributable to timber production activities, including mitigation measures necessitated by the impacts of timber production." Id. at Section 219.14(b)(2) (emphasis added).

The Commission is concerned that the Forest Service will respond to the "sales below cost" controversy by artificially "improving" its timber sale balance sheet by shortchanging mitigation needs. The DEIS should disclose the manner in which mitigation measures and levels of mitigation funding are chosen and applied. This information may demonstrate that the timber production envisioned by the proposed alternative fails to include all mitigation costs and is therefore even more cost ineffective than it presently appears. Bland assurances that the Forest Service will implement mitigation measures which it alone determines are necessary frustrates the policies behind both NEPA and NFMA. Both of these statutes demand disclosure, public scrutiny, and public input.

In attempting to "justify" "sales below cost," the Forest Service should explain where it intends to find the funds to pay for mitigating the effects of timber management on fish and wildlife. It is our understanding that Knutsen-Vandenberg funds for fish and wildlife are not generated by "sales below cost"

whereas a sale that covers its costs also yields mitigation money. In other words, fish and wildlife are much more adversely affected by a below cost sale than by a sale that is financially sound.

Budget

Given the present domestic spending trends, it is extremely unlikely that the Forest Service will be able to count on receiving budgets of equal or greater amount than what it currently gets. The DEIS should include a complete explanation of how the WNF will respond to budget cuts, which programs will be cut and the amount of the cuts.

Neither the plan nor the DEIS explain the role of Bonneville Power Administration funding of Fish and Wildlife Program measures on the WNF. Without a thorough discussion of BPA funding, the public may suspect that BPA dollars are being used to displace habitat protection activities for which the Forest Service is responsible. This fear is being confirmed by the WNF. In discussing cumulative effects in the Upper Yakima basin, the DEIS declares that "[a] more detailed study of these potential effects is recommended and could be implemented as a basin-wide study under the auspices of the Northwest Power Planning Council's Fish and Wildlife Program." DEIS at IV-39. Since these potential effects are the product of timber harvest on private and WNF lands, a cumulative effects analysis is clearly the Forest Service's obligation.

Hydroelectric Applications

The Secretary of Agriculture has an important role to play in the licensing of hydroelectric projects that will be located in national forests. Section 4(e) of the Federal Power Act, 16 U.S.C. Section 797(e) (1982) declares that the Federal Energy Regulatory Commission is authorized:

To issue licenses...for the purpose of constructing dams...or other project works...upon any part of the public lands and reservations of the United States...Provided, that licenses shall be issued within any reservation only after a finding by the Commission that the license will not interfere or be inconsistent with the purpose for which such reservation was created or acquired, and shall be subject to and contain such conditions as the Secretary of the department under whose jurisdiction such reservation falls shall deem necessary for the adequate protection and utilization of such reservations....

It is the Forest Service's duty to impose terms and conditions that will assure adequate protection for national forest lands from the harms resulting from hydroelectric development. See Escondido Mutual Water Company v. La Jolla and Rincon Bands of Mission Indians, 104 S. Ct. 2105, 2114-15 (1983). It is also part of the Forest Service's trust responsibility to the tribes to ensure that it exercises its duty to impose terms and conditions so that the tribes' treaty rights are protected. The tribes possess considerable expertise in this area and would welcome further consultation with the Forest Service to ensure adequate protection.

The Northwest Power Planning Council is in the process of developing a list of potential hydro sites with the least potential for adverse impacts on other resources. Forest Service activities related to hydroelectric power should be coordinated with these efforts.

Anadromous Fish Concerns

Our review of the Wenatchee's draft planning documents revealed several weaknesses in the fish management sections. Foremost of these is the already noted lack of basic information. But what bothers us even more is that there is no clearly defined plan to obtain the missing data. Throughout the fish sections we encounter statements indicating that the information presented is approximate, based on incomplete knowledge, or is simply a judgment call, but nowhere do we find a strategy for filling in the gaps. How does the Forest intend to begin answering the ten questions outlined on page II-70 of the Plan?

What ten year period was used to develop the forest's average present anadromous fish escapement figure (Plan II-23)? Recent returns, at least to the Yakima system, are considerably greater than those indicated and we question whether the figures presented accurately reflect the present escapement condition.

Why is smolt habitat capability assumed to require full escapement on the forest (Plan II-24)? Assuming conditions in the habitat are not widely fluctuating then its capability will remain unchanged regardless of escapement level. The number of smolts produced may vary with parent escapements but the habitat's ability to sustain them is a variable independent of fish numbers.

The Forest's estimated commercial and sport harvest potential (Plan II-24) is misleading: What mortality rate is referred to when it is assumed that "off-Forest dam losses are nearly eliminated"? Given presently available technology we can, at best, anticipate a reduction in average per-project mortality from the existing 15 percent to something between 5 and 10 percent. That's still a far cry from near elimination of mortality. Those same anticipated harvests are also based upon the assumption that the systems will "produce fish to their

maximum potential". Is this a realistic condition to expect? Naturally operating systems rarely, if ever, produce any one species (or group of related species) at a maximum rate. Rather, balanced systems simultaneously produce numerous species at rates below any one's maximum. This helps to maximize species diversity and the occupation of all available ecological niches. Continuously maximizing any particular species can only be done at some other species' expense, and such a condition is indicative of a system out of balance. The potential harvest figures, therefore, need to be based on more realistic assumptions and recalculated. Further, it would be helpful if these tables displayed (1) applied smolt-to-adult survival rates, and (2) more consistent units (e.g. smolts produced and number of adults harvested rather than smolts and pounds of fish harvested.)

The Wenatchee National Forest's responses to issues, concerns, and opportunities (Plan, Chapter III) contain confusing, often faulty implications. While discussing wildlife and fish (III 4-5), for example, the Plan states: "Water quality may often limit the Forest's fisheries production potential. For instance, most of the streams exhibit very low water temperatures year-round due to their high altitude and have low nutrient content which results in slow fish growth". Such statements imply that cold, relatively sterile water is of low quality. This is simply not true. Water "quality" is a reflection of conditions that produce it. Pacific NW fish species have evolutionarily adapted to conditions, one of which is water quality, shaped by the region's long term climate, geology, and vegetation. If they hadn't they wouldn't be here in the abundance that they are (or at least were prior to technological man's intrusion upon them). It is illogical to thus infer that any major component of a successful system, such as water, would be of "low" quality. We must assume that well established fish species (or other long-time forest occupants) are well adapted to the water produced there, that it is apparently of sufficient quality to meet their requirements. So if their growth (for instance) is slower than that of another, similar species or stock in another location with different environmental conditions, this situation does not reflect, and should not be interpreted as reflecting, poor quality conditions in the former location. When the Forest Service insinuates that various habitats can be "improved" by warming the water and adding nutrients it displays both an ignorance of the adaptive process and ramifications of sudden environmental change and an arrogance about its role as land manager. As habitats are manipulated for man's benefit, many of those species that existed well in the unmanipulated habitat will likely decline in number. The alluded to "improvement" reflects a totally anthropocentric viewpoint.

This attitude is reflected elsewhere in the Plan. In the same section (III-5), for example, we find the statements: "The plan will maintain or enhance wildlife diversity by the identification and management of essential wildlife habitats. Non-game populations will be maintained while deer and elk

populations will increase". Our immediate response is, what habitats does the Forest consider to be non-essential? Also, if deer and elk are to be emphasized then a greater proportion of the forest will have to be maintained in earlier successional stages that favor such species. This, in turn, will restrict the amount of forest available to species that do not thrive under these conditions. So it is highly unlikely that the forest plan can fully achieve both intended goals. If one, or a group of, species is favored it will be at the expense of something else. The forest is not a bottomless cornucopia of resources; there are finite limits on what it can and will produce. Statements or implications to the contrary are false.

One extremely troubling aspect of Wenatchee's draft plan is its constant reliance on outside programs or agencies (e.g. Northwest Power Planning Council, BPA, and Bureau of Reclamation) as means to stem and reverse declines in numbers of anadromous fish returning to upper Columbia River watersheds. By so doing, the Forest implicitly absolves itself of any responsibility for having contributed to those declines. Simultaneously, however, the planning documents recognize that "{t}imber harvest, and roading due to timber harvest, are man's activities which would have the greatest potential to reduce fish habitat capability on the Forest" (Plan IV-45). Surely the Forest can see that, given the existing obligations (and ongoing efforts) to rebuild depleted Columbia River fish runs, reducing fish habitat capability is tantamount to reducing fish numbers. Forest management activities on the Wenatchee, therefore, do have direct impacts on the forest's fish resources. As a result, Wenatchee National Forest must include in its management plan a clearly set forth program of how it intends to replace fish lost as a result of its silvicultural activities. The Forest cannot simply rely on other programs to increase escapements, wait until some establish residence on its lands, and then take credit for increasing production. As long as some forest management activities directly contribute to declines in fish numbers, then other forest management activities must be carried out for the express purpose of replacing those losses. Habitat improvement projects dependant for funding upon other, fish habitat capability-reducing activities (e.g. those funded by timber sale-generated KV funds) are insufficient. The fish's welfare cannot be held hostage. Past timber sales, for instance, have damaged fish habitat with virtual impunity. Continuation of the timber program cannot be a prerequisite to rectifying that condition. The Forest must realize that it has a duty to protect the entire spectrum of forest resources and that the days of some resources being more equal than others is past.

Wenatchee's Fisheries Inventory/Improvement program, outlined on page IV-44 (Plan), indicates that an average of \$111,000/year will be spent. Of this amount, \$86,000 (77%) will be KV monies; the remaining \$25,000 (23%) will be appropriated funds. In other words, better than three quarters of the anticipated habitat work will be entirely contingent upon implementing a successful, profitable timber sale program! Such

an approach concerns us for numerous reasons. Initially, fish habitat damaged by past timber sale activities will not likely receive benefit from these funds unless a new sale that generates KV dollars occurs in the same general area. Assuming that most new sales will be laid out in new areas, then most damage from earlier sales will likely stay unfixed. And if this is the case, then the forest's existing habitat deficit will simply remain.

What information does the Forest have that leads it to believe that future timber sales will be so profitable that they will generate sufficient KV dollars to supply that program's other responsibilities (e.g. replanting cut-over lands) as well as the \$86,000/year that will fuel the habitat work? Have past timber programs been so lucrative? Will the fluctuating timber market lend its support? We remain somewhat skeptical and question the wisdom of assuming that all will work as smoothly as the Plan would have us believe. Because if it doesn't, the habitat disturbing activities will likely have occurred (timber programs are hard-money based) but the "soft" KV dollars necessary to put damaged habitat back together may not be available. Where are we then?

The draft Plan clearly recognizes the demand for increasing the fish resource on Wenatchee forest lands. It also notes the massive efforts being expended elsewhere to help satisfy that demand. Why then is Wenatchee's commitment to this aspect of forest management so tenuous? Surely a case could be made to support a request for appropriated funds or other hard monies with which to initiate the much needed fish program on Wenatchee National Forest. Until such time as the Forest Service is willing to demonstrate that its commitment to managing the so-called amenity resources is similar to its commitment to commodity resources, it will not deserve the confidence of agencies or people who recognize the major imbalances in its management programs.

TIMBER

Harvest levels

Current timber harvest level is 170.9 MMBF with 5.9 MMBF of unregulated harvest for a total of 176.8 MMBF (Plan-II-27). The ten-year average (1975 to 1984) harvest of green timber was 146 MMBF. During this period the actual volume offered was 184 MMBF; the volume sold was 164 MMBF. Presently 850 MMBF of uncut timber volume is under contract. Allowing that timber companies usually keep a two-year volume on hand at any time, they have 478 MMBF of uncut volume which can be added to any new purchases (Plan-II-30). The Plan will decrease the total sale volume to 78% of the current management plan (Plan-III-7). Under Alternative C the chargeable volume is 129.7 MMBF and the total volume is 138.1 MMBF. Given the large stockpile of sold timber volume which can be added to the harvest planned for the next decade, a total volume of 185.9 MMBF could be harvested per year for the next

decade. This harvest magnitude is essentially a departure from the current harvest level. If federal timber had been more expensive the logging companies would not have bought it and built up a stockpile. If these companies did not have their stockpile, the WNF would not increase their offerings in any year to make up for any reduction in harvest during a previous decade. To prevent cumulative effects of logging by various logging companies working in a basin, there should be an annual limit on harvest volume as well as sale volume. That is, harvest volume should not exceed LTSY. Buying timber when it is cheap, stockpiling it and then cutting massive amounts when a profit can be made might be justifiable by the timber companies but intensifies the burden carried by the environment.

Timber Yield and Prescriptions

Timber yield tables for the general forest and for special prescriptions involving long rotations are given in the Plan (IV-49). Prescriptions for the general forest are GF-1, 3, 4, 5, and 6. These represent high to low silvicultural investments (primarily level of planting and thinning and harvest method). Only 3961 acres are allocated to GF-1 and 242,490 acres allocated to GF-4. With the silvicultural treatments provided on GF-1 acres, the average annual growth at culmination (CMAI) would be 60.3 ft³/acre/yr on wet forest types. On GF-4 lands this figure is 57 ft³/acre/yr. On GF-1 land trees reach 19.1 inch DBH at CMAI at 110 years while under GF-4, trees reach only 10.1 inch DBH at 110 years old. Although the growth rates at CMAI are provided for comparison, what are the differences in resulting timber volumes for the two prescriptions? On the surface it appears that it would be worth treating more land with the GF-1 prescription because in wet forest, 7 to 9 inch trees are worth \$222 and 19 inch trees are \$525.50. Even larger trees can be worth up to \$613.94. How do the economics of silviculture and harvest of trees in GF-1 vs. GF-4 compare? How will wildlife populations fare on such massive devotion to GF-4 compared with GF-1? Will local mills be able to retool to handle the much smaller logs and will these logs satisfy the full range of future demand for wood products?

"Volume projection for existing stands is very important because predicted yields are critical in the determination of allowable sale quantity" (Appendix-B-53). A land prescription such as GF-4 accounts for a large acreage. How accurately does a single yield table represent such an area? How homogenous is an area such as represented by GF-4 lands? Have experimental plots been studied on steep hillsides of different slope gradients, altitudes, aspects, and soil types to explore the range of growth response? How well have the topographic and soil conditions been evaluated for each management prescription in arriving at a real average yield table for each?

The average net growth on the WNFs existing timber stands is 29 ft³/acre/yr. Additional yield can be achieved by the following treatments: planting genetically superior trees- 10%;

thinning of stands- 10%; disease and insect losses- 30%; harvesting trees at culmination- 50%; fertilization- 7%. These treatments amount to 107% increase. Are all these treatments necessary to achieve the growth attributed to GF-1? When it is stated that 50% more growth can be achieved by harvesting at CMAI (110 years for wet forest in GF-1) rather than allowing growth to slow down, what age forest is the one at CMAI being compared with? It would seem that terminating growth at culmination is premature. During all the growth of any given forest plot prior to CMAI, the volume increments were less than at CMAI. If the decline in growth rate were precipitous it might be justified to cut the trees at CMAI but if the growth rate 50 years after CMAI is equivalent to that 50 years before that point, there is no more reason to stop growth at CMAI+50 than at CMAI-50. Letting trees get larger makes them more valuable in addition to providing more wildlife habitat, vegetation diversity, and less sedimentation.

Table IV-9 (Plan-IV-52) presents the present and future conditions on the WNF related to growth, mortality, and growing stock of trees. Presently annual net growth is 25.9 MMCF/yr; annual mortality is 10.2 MMCF/yr. Total annual growth is then 36.1 MMCF. The timber sale program is 25.3 MMCF/yr offered for all 50 years (Plan-IV-27). The ASQ of green trees is 23.8 MMCF/yr. Annual net growth minus ASQ equals 2.1 MMCF/yr which should be added to the growing stock. Annual growth is shown to increase from 25.9 to 27.0 MMCF/yr in the future forest so the growing stock should increase even faster than 2.1 MMCF/yr with time. Why is there such a drastic decline in the growing stock (i.e. from 2056 to 1580 MMCF)? The LTSY for alternative C is 29.3 MMCF/yr. Why is timber growth in alternative C listed as 19.7 MMCF/yr in year 2030 (DEIS-II-113)?

Using the conversion 5.45 BF/CF (Appendix B-79) one could calculate that 8.8 MMCF will be added to the annual harvest for the next decade solely through the harvest of the stockpiled volume. This means that 32.6 MMCF/yr could be harvested. This harvest level, which is above the LTSY, appears unwise. It could not, however, account for the large decline in growing stock. How does this decline occur?

Under alternative C there will be a suitable timber base of 643,898 acres. The acreage allocated yearly to various harvest techniques will be: clearcut- 1934 acres; shelterwood- 5026 acres; selective cut- 2896 acres; total cut from 9856 acres. Will these selective cuts be primarily small clearcuts or primarily individual selection. Clearcutting in the past has been 3000 acres/yr (DEIS-III-62) so there is apparently an effort to reduce acres of clearcut. Is this change designed to meet an MMR?

Special Harvest Prescription

The special timber harvest prescription SP-2 will be used in EW-1 and EW-2 management units. This special yield table

requires "long-rotations of up to 260 years" (DEIS-IV-44). What does "up to 260 years" imply? Establishing 260 years as a rotation age is an important new concept in timber management (see L.D. Harris, 1984, "The Fragmented Forest" in which long rotations of 320 years were proposed). What is the frequency distribution of forest site types in the EW-2 zone. It could be a concern that poor sites would not allow old growth characteristics to emerge at stand ages less than 260 years.

A comparison of the GF and SP yield tables raises some questions. The GF-1 prescription has a pre-commercial thin and a commercial thin at age 70 to 90 years and has 54 trees per acre at CMAI at 110 years. The SP-2 yield table used in EW-2 (riparian) has only a precommercial thin and has only 20 trees per acre at 130 years. Why is there this great difference in number of trees per acre? Riparian zones should be an area of greater than average tree production so the low tree density and timber production here is peculiar. What tree densities in old growth stands are typical in different areas of the forest? Is the low timber production in the EW-2 area compared with GF areas solely a result of the different stand ages used (110 years for GF-1 and 130 years for SP-2)? What is the growth rate in EW-2 areas at 110 years?

If 25 foot riparian zones are the rule on low gradient, highly productive anadromous streams, one could expect a tree stem every 87 feet (using 20 trees/acre as a wet forest density). The S+Gs for EW-2 suggest that the leave trees in this zone could be concentrated near or away from the stream depending on how much light is desired in the stream bottom. If the riparian width is 25 feet, concentrating the trees along the stream essentially means having a "picket fence" along the channel.

How exactly would a long-rotation work? Would half of the initial stand be removed on the first commercial cut and half on the second cut? Removing more than 50% on the first cut could simply remove the oldest trees and leave only trees significantly less than 130 years old. These trees would then not be able to reach 260 years old by the second cut. This process would reduce the effective maximum stand age from 260 years to something much less. Trees of greater than 130 years old should be left to produce 260 year old trees in the regenerated stand. These trees should represent a frequency similar to a normal old growth stand. Which tree species are to be left after a first cutting? Will the leave trees represent the species mix found originally? If a riparian community has been managed in the past, will future management provide the species composition which might have been found before any management? For example, is cedar to be a component of the riparian community of the future? Will presently managed riparian zones be allowed to attain 260 years of age before further cutting?

Local Communities

Typically timber harvest is justified in the interest of

supporting local communities. Longview Fibre and Plum Creek export a significant amount of logs to Pacific-rim countries. What fraction of trees taken from the WNF is simply shipped overseas for further processing. It would seem that the argument of supporting local mills and economies with high levels of harvest is unjustified if these logs are shipped out of the community.

Historically, local mills depended for about 60% of their timber demand on the WNF (DEIS-II-65). New mills are proposed at Entiat and Pateros with a capacity of 50 to 70 MMBF. If privately owned timber is largely gone, where will these mills get their timber? Can the forest afford to encourage more mills to be dependent on national forest timber when these mills do not plan on future extinction of private holdings? These companies plan to "liquidate their timber assets within the next decade" (DEIS-IV-76). These companies are unable to produce timber at sustained yields so intend to try to pass on a "liquidation" mentality to the Forest Service and see the high value fish, wildlife, and recreational base sacrificed.

Revegetation

Only 6 of 16 tree species on the WNF are considered important enough commercially to warrant investment in tree improvement (DEIS-III-60). These trees are Douglas fir, ponderosa pine, western white pine, noble fir, pacific silver fir, and western larch. There are seed orchards for all but western larch. Even though revegetation will be done by mixed planting, it would seem than with the enormous acreages involved that some tree species which are presently in low densities will become even rarer. Cedars, for example, are in high demand and were once common in riparian zones. How will this and other species fare in the future and how will demand for these trees be met?

Land suitability

About 30% of suitable timber land occurs on slopes suited to use of tractors and rubber tired skidders (DEIS-III-144). These vehicles cause soil compaction. On steeper slopes the incidence of surface erosion and mass failure increases. Lands listed as having regeneration difficulty include those on slopes greater than 99% (Appendix B-11). Why was such a steep slope chosen as a baseline for concern? Has it been found that on all soil types that 99% is the point at which erosion hazard increases dramatically? An information need for soils is to find the amount of canopy which can be removed "before failures start to move" (Plan-II-72). Hopefully, the goal is not to see exactly how much can be removed in an effort to get the slope just within the critical point.

Of the old-growth lands, 87,584 acres are considered suitable forest land and 34,529 are unsuitable. What makes these

lands unsuitable? Are they less than 10% stocked? How will the unsuited lands of old-growth be used to meet the needs of old-growth dependent species?

Roadless Allocation

There are presently 694,200 roaded acres on the WNF out of a total of 2,164,180 acres (DEIS-III-55). On the suitable dry and wet forest there are a total of 492,182 roaded acres. There are 643,898 suitable acres designated in alternative C (Plan-IV-47). This would indicate that 151,716 acres of suitable forest are to be roaded under the preferred alternative. However, adding up the acres to be roaded from the 23 inventoried roadless areas (DEIS-II-27) shows that 288,702 acres will be roaded. Unfortunately, in order to add 151,716 more acres to the timber base about twice that area will be roaded. Of the 23 inventoried roadless areas only 8 will leave greater than 50% of their area as roadless, whereas it is stated that 19 of the 23 will have a "substantial" portion maintained as roadless (DEIS-II-27).

The DEIS (II-102) shows wilderness use to be the same for all alternatives in every decade. With the large differences in roadless area available among alternatives, is it reasonable to assume that the lack of roadless-non-motorized recreation in one alternative would not be met with higher use of the wilderness areas?

K-370 Wild and Scenic Rivers

Timber harvest allocations would preclude possible Wild designation on some rivers (DEIS-IV-109). Does this occur in alternative C? Only the Chiwawa, White, and Wenatchee Rivers are proposed for classification in alternative C, whereas some other alternatives propose the Entiat, N.F. Entiat, and Mad Rivers. The DEIS (IV-126) claims that the Mad River, Swauk-Naneum Creek and Naches River minor tributaries have more than 50% of their area allocated to harvest prescriptions; the Entiat River, Mission Creek, and Taneum-Manastash Creek watersheds have more than 40% allocated to harvest prescriptions; all others have less than 40% so designated. The Little Naches River at 50% timber harvest allocation was overlooked. Also, when private acres are included in the analysis of percentage of the subwatersheds allocated to timber harvest, the picture is much different. There will be 24 of the 27 subwatersheds in which more than 50% of the basin will be harvested (DEIS-IV-67).

ROADS

Road density

Alternative C will result in new road construction of 1710 miles in the next 50 years. Of this, 810 miles of road will be constructed in unroaded areas and most of this will occur in the next 24 years (DEIS-II-30). Since most of the road mileage will be concentrated in the suitable forest land, the construction of

810 miles of road on 151,716 acres equals 3.4 mi/mi². This road density is what would be expected on gentle slopes (Plan-II-54). Much lower road densities would be found on steeper slopes. Why is the typical road density of roaded areas for the WNF listed as 3.75 mi/mi² when densities as low as 1.1 mi/mi² are found on steep slopes? If the WNF will be fully-roaded within the next 24 years, why are sedimentation peaks occurring in the 14th decade? Considering the increasing demand for wilderness and roadless recreation and the critically short supply of wilderness recreation, why does the road-building policy advocate massive upfront construction? This seems to preempt any further consideration of many roadless areas from protection or use as recreation areas and concentrates sedimentation into the next 3 decades.

Road density in the past has averaged 4 mi/mi². Current roading practices will reduce this to 3 mi/mi² on newly roaded lands (DEIS-IV-92). However, because the remaining timber base will be on those lands of greater than average steepness, this reduction in road density may reflect a change in harvest method rather than roading method. It is stated that "though new roads will be required, 50% of them will be closed, and a sufficient number of existing roads will be abandoned" (DEIS-IV-92). Timber yield lost due to long-term service roads is 4.4% and that due to spur roads is 1% (DEIS-III-146). If by closing 50% of the roads we arrive at a road density of 3 mi/mi², then the road density just after logging is 6 mi/mi². If timber yield lost due to roads totals 5.4% at a road density of 6 mi/mi², the road width would be 47.5 feet. If only permanent roads are considered, the road width would be 39 feet. Where is the error in these calculations? Possibly actual road densities are really higher than stated; or the degree of road closure is not as high as stated.

SOILS AND SEDIMENT

There are four major watersheds on the WNF which are considered separately in planning- the Chelan, Entiat, Wenatchee, and Yakima. In the WNF as a whole there are 200 different kinds of soils and 30 different geologic formations. The reason for this wide range of environmental conditions is the broad range of altitudes (750 to 9000 ft) and annual precipitation (10 to 120 inches). Soil Resource Inventories (SRIs) were used for general planning including identification of unstable soil areas and areas with regeneration problems. The SCS is currently completing intensive soil surveys on most of the WNF. Yakima county still remains to be studied. Intensive surveys will be available for the WNF in 3 to 5 years.

Which areas have been identified as unsuitable for timber harvest because of concern for soil productivity? Are there any guidelines as far as slope gradient, soil composition or type, landscape sensitivity (e.g. concern for fisheries), sediment yields or surface erosion levels which make harvest unthinkable? In which cases are harvest methods and scheduling simply adjusted

to allow harvest? The four major basins are rated for cumulative effects of soil erosion, compaction, nutrient loss, and mass wasting hazard. All four basins are listed as having possible cumulative effect problems with the four soil effects. It is assumed that negative effects can be avoided by proper management. If this is the case, why are mass failures and surface erosion so common in some basins?

Chelan soils are non-cohesive and are easily moved when surface vegetation has been removed (DEIS-III-82). While the Chelan occupies the position of least hazardous soil conditions, it would appear that under timber harvest activities, the possibility of surface erosion is very likely. "Slumps and debris torrents are an ever present risk" (DEIS-III-82). The description of the Entiat is very similar to the Chelan except for more widespread slumps and earth flows (DEIS-III-83).

Soils of the Wenatchee basin can be very erosive, many soils are prone to compaction, and mass failures have occurred recently in some areas although the basin is fairly stable to this form of erosion. The Chelan, Entiat, and Wenatchee basins are described as having very thin 'A' soil horizons. Because this soil layer is so thin, any additional surface erosion above background could constitute a serious loss of nutrients and reduction of site productivity.

It is peculiar that for each basin the potential effects of wildfire and controlled burning are emphasized over logging effects as the major cause of nutrient loss. The loss from fire was described as nutrient volatilization. Volatile elements in soil are principally N, S, P, and Cl with N being the major element of concern (Wells, C.G. et al, 1979, USFS Gen.Tech. Rpt. WO-7). Nitrogen, however, can be replaced through fixation by nodulated species. These species are often the ones which are excluded by chemical or mechanical means during the revegetation period. Wildfire is certainly a normal factor operating in the ecosystem. If these basins had experienced cumulative nutrient losses over thousands of years, they would not be so productive for tree growth. It is, then, not natural events which so much direct the trend in productivity, but management activity. If it has been decided that prescribed burns followed by suppression of grasses and shrubs are to be management decisions, it is the responsibility of the WNF to determine how productivity can be maintained. There is a tendency in the Plan and DEIS to emphasize accidents of nature as causes for negative effects and to downplay the negative effects of management or even to portray them as beneficial. Adequate ground cover is the primary factor responsible for maintenance of soil productivity and control of soil erosion. Loss of nutrients is much more substantial through soil erosion than by volatilization and it is logging, roading, and livestock grazing which are the primary determinants of future productivity trends.

The Yakima Basin has a wide variety of soil types. It has problems with surface erosion, compaction, and mass failures.

This basin is described as having the most serious soil erosion hazards of the four major basins. What special precautions in timber harvest are being exercised in the Yakima Basin to minimize soil erosion? What will substitute for intensive soil surveys here during the time (5 year period) in which these surveys are being completed?

In the course of an inventory (1978-1979) of degraded acres on the WNF, 143 sites were listed as needing rehabilitation. These sites were termed significantly damaged and eroding. Can rehabilitation really be accomplished on these sites? Since this survey was not completed, one wonders how extensive are the acres of degraded sites. How soon will the survey of degraded sites be restarted and what progress can be made on rehabilitation of all presently degraded sites in the next 10 years?

Index values to soil erosion were calculated for each alternative in the DEIS. The background level of delivered sediment is 930,500 tons/yr. During the first five decades, delivered sediment is below 44,100 tons/yr in alternative C. In decades 6 through 10 sediment levels double (DEIS-II-29). Delivered sediment levels from management activity are lowest in year 2030 in alternative E (23,700 tons/yr) and highest in alternative B and H (87,200 and 71,400 tons/yr, respectively) (DEIS-II-29 and IV-73). Alternative B shares the highest percentage intensive timber management (68%) and has the greatest percentage of clearcuts (66%) (DEIS-IV-75). Alternative D has only a slightly lower percentage of clearcuts (58%) but has considerably less delivered sediment than alternative H which has a lower percentage clearcut (50%). What management options were employed in alternative D to reduce sedimentation below that found in alternative H? Both D and H have approximately the same timber base and differ by only 11 MMBF ASQ. Why does H rise so rapidly from the third decade onward? Why do all alternatives have a sharp peak in sedimentation in the sixth decade? It appears that overmanagement reaches a critical threshold by the end of the planning process (5th decade).

Sediment yields were calculated from the Modified Universal Soil Loss Equation (Appendix-B-62). Which studies have established the validity of using this model as a predictive tool for the forest environment? The model might have general applicability on farmland with gentle slopes but it is questionable whether it is suitable for use in the WNF. What kinds of correlations between predicted and observed sediment values have been calculated? Are there any watersheds on the WNF for which recovery of instream sediment composition has been observed? It would seem that if background level sediment output from the WNF is based on incidental observations of suspended sediment and linked to an erosion model intended for use in a very different physiographic area, the results would be tenuous. Further, if activity related sedimentation provides only an index, there is no assurance that the relative levels of background and activity sediment are reasonable. While index values in one alternative may be twice that shown in another, it

might be argued by some that the increases are all negligible in relation to the background. This kind of statement would assume that we know with certainty the background level or the relative sedimentation levels of background and activity. The accuracy of estimates of the relative levels of activity derived sediment among alternatives is only as good as the accuracy of measures of erosion from different soil units under different treatments or the assumed indices of erosion of soil units.

Alternative E has a lower timber base (524,170 acres) than A, B, D, H, and I. It has 23% of the timber base managed by intensive harvest and 14% by clearcut. Consequently, it has the lowest delivered sediment. Alternative F is also comparable in management plan and sediment output through the first five decades.

Soil loss will reduce the long-term soil productivity by affecting total soil depth, and lowering soil water holding capacity, organic, and nutrient supply (Plan-IV-61). Because of the shallow A horizon depth on the WNF, the broad extent of management activity, and the tendency of management to accelerate erosion, knowledge of actual erosion rates is essential. While the index values may be of help in choosing among alternatives, they do not provide insight into actual erosion rates induced by management (Plan-IV-61). How have sediment inputs from mass erosion been accounted for? Have mitigation factors been employed in calculations of erosion from roads? Would different qualities of roads be built in the various alternatives and how do erosion rates vary on these? If the WNF instituted a policy of road use only during logging activity and then closing and seeding the road, what effect would this have on sediment outputs? If roads are the predominant source of accelerated sediment and decline in their sediment output is very slow, a policy of extensive closure would be advantageous. Benefits to fish, wildlife, and water quality are obvious. Does the WNF have the budget to maintain all roads which will eventually be found in a fully-roaded commercial forest land base if they are all to be kept open? Are there plans to develop models for accurately predicting sediment outputs under different combinations of soil type and management activity?

RANGE

The information on range is difficult for a reader to assemble in a way that allows a reasoned choice of alternatives. Some data will be tabulated below from the Plan and DEIS.

(Plan-II-32 and DEIS-III-67)			
Total forest suitable rangeland	401,000 acres		
Suitable range outside allotments and wilderness	197,639 acres	49.3%	
Suitable range in all allotments	203,461 acres	50.7%	

Estimated total livestock grazing capacity in allotments	27,517 AUM
Estimated grazing capacity outside allotments and wilderness	9,514 AUM
Total forest grazing capacity	37,031 AUM
1984 actual use	20,524 AUM

(Plan-II-66) Current outputs and supply potential

Under current grazing program	
1986	36,800 AUM
2030	39,100 AUM
Production potential	
1986	38,200 AUM
2030	40,700 AUM

(Plan-II-31 and DEIS-III-66)

Total annual forage production	336,000 tons	% of total	100.0
Forage available on steep slopes (i.e. greater than 60 degrees)	112,000 tons		33.3
Forage on steep slopes available to wildlife (10% of 112,000)	11,000 tons		3.3
Forage on gentle slopes	224,000 tons		66.7
Forage unutilized by animals	159,000 tons		47.3
Total forage available to wildlife and livestock (130 MAUM)	65,000 tons		19.4
1984 forage used by livestock	20,500 AUM		
1984 forage left for wildlife	109,500 AUM		
Current management potential of Forest to produce forage for livestock	37,031 AUM		

(DEIS-III-66)

Total forest area	2,164,180 acres
Area suitable for grazing by livestock	400,373 acres
Area outside wilderness capable of providing forage after silvicultural practices	500,871 acres

The data above make several assumptions possible. It appears that there are about 400,373 acres of suitable range

K-372

(note discrepancy between Plan-II-32 and DEIS-III-66). Of this area 50.7% is in allotments. 49.3% of suitable range exists outside allotments and wilderness. How much of this area is grazed by livestock? Table IV-17 (DEIS) indicates that 571,300 acres will be grazed at high and moderate intensities and 326,900 acres will be grazed at low intensities in alternative C. Because suitable range is found on only 400,373 acres, it appears that 170,930 acres of timber land or wilderness will be grazed at high to moderate intensity. Why is this allowed? Are there wilderness allotments? Is grazing within allotments termed high intensity; is grazing in wilderness areas low intensity? How much of the grazing program depends on transitional range and what grazing intensity is proposed here? Grazing on transitional range is apt to increase erosion, slow the recovery of cutover sites through trampling of seedlings, increase the number of seedlings which need to be planted to achieve full stocking after 10 years, and necessitate expansion of the timber base to provide the same LSY possible without grazing of transitional range. Are there any studies to show that these concerns are unfounded? Which studies show that increased tree growth and survival occurs under grazing by cattle? Why is it acceptable to delay revegetation by 10 years but not to allow trees to grow past CMAI?

Aside from suitable rangeland there is an additional 500,871 acres of the WNF outside wilderness which is able to provide forage as transitional rangeland. How many of these acres at any instant in time during the 50 year planning period will be transitional range? Total annual forage production is 336,000 tons. Is this the amount produced on the 898,184 acres of suitable grazing land (DEIS-II-31). It is assumed that 47% of the forage produced either dies and is recycled or is the standing crop needed for future production and soil stabilization. Only 19.4% of the total annual forage production is available to livestock and wildlife. Of the total AUMs of forage, 16% (20,500 AUM) is allocated to livestock. Over the 5 decade period livestock numbers would be increased so that they consume 29% of forage. There is a current management potential to produce 37,031 AUM of forage for livestock (compare with stated potentials of 35,600 AUM in DEIS-II-31 and 38,200 AUM in Plan-II-66). What is the distinction between the current 1986 grazing program in terms of AUMs and the production potential? It appears that the current program is close to potential. What factors produce this situation?

It is reported that there are 22000 deer and 7000 elk presently. If the average deer weighs 200 pounds and an elk 1000 pounds it would appear that 137 MAUM of forage is required although only 109.5 MAUM are estimated in the Plan. There are WNF requirements for amount of forage to be left for watershed stability needs. If a greater amount of forage is really needed by wildlife as indicated above and the watershed requirement is fixed, isn't it dangerous to continue increasing the share allotted to cattle? Although it was claimed that allowances were made for environmental conditions, how many AUMs extra are there

which could be consumed by game? Are deer and elk numbers the only game considered in forage consumption by wildlife? How much is utilized by all other wildlife which must survive on allotments? What happens when abnormally dry conditions occur? Do range specialists ever monitor forage production throughout the grazing period each year to determine when cattle numbers should be reduced? Are cattle ever removed from the range ahead of schedule to protect the watershed, riparian zone, and wildlife forage for the winter season?

Most Forest Service plans claim that competition between cattle and deer is negligible. The WNF Plan, in effect, identifies cattle as the savior of deer by keeping shrubs from growing out of reach. If cattle are performing this service they are either trampling the shrubs or are eating deer food. Although the WNF does not appear to discount competition, it is always surprising how the actions of cattle can be glorified when the need arises.

There are 36 livestock owners with permits on the WNF (DEIS III-7) for grazing on 40 allotments. Only 15 of these jobs are provided to Chelan, Kittitas, and Yakima counties (DEIS-III-148). Current grazing on the WNF amounts to 2990 head of cattle. The number of cattle on the WNF comprises only 2% of the number found in the three counties centered on the Forest. Permittees depend on spring, summer, and/or fall grazing to balance their year-long grazing program. A few depend almost exclusively on the WNF resource (DEIS-III-68). If actual grazing is at the high end of the last 5 year level (20,500 AUM)(DEIS-III-68), then cattle can be expected on the WNF for 7 months of the year. Rather than a small dependence, most grazing on the WNF is done by ranchers relying heavily on the federal subsidy. It seems obvious that the generally minute dependence of the three county area for grazing on national forest land is insignificant. The small percentage of 40 permittees which may be totally dependent on grazing on the WNF amount to how many individuals? Are they dependent on the WNF because of custom, location of their ranch, or unwillingness to pay fair market rates for forage? Considering the great expense to the public in providing all the needed developments on the range to facilitate grazing for permittees (e.g. fences, springs, cattleguards, weed control, driveways, seeding, corrals, pipelines, bridges), how can the WNF continue the deficit spending on range and then not finance needed improvements to stream habitats and degraded sites on watersheds. It was stated that a high investment is required by both permittee and Forest Service before forage can be made available to cattle (DEIS-III-68). How much do permittees provide for range improvements beyond their grazing fees? How great is the financial loss to the WNF when the total expense of the range program is balanced against the minimal grazing fees?

Several poorly documented assertions are made regarding range which heavily influence the predicted effects of livestock. A reference to Scotten (1980) (not provided in literature cited) claimed that there was a big opportunity for improving wild

ungulate habitat by logging and range production (DEIS-IV-52). Supposedly more bluebunch wheatgrass seedlings become established under intensive management than under continuous grazing or complete lack of grazing. Also, after several years, soil cover and plant composition and densities are better outside exclosures where both livestock and wildlife graze (DEIS-IV-52). A related assertion is that grazing of suitable range through intensive systems will maximize production of forage for wildlife in key wildlife areas (DEIS-IV-56). Is stimulation of forage production by wildlife grazing considered insufficient to maintain plant diversity and density? How did plant or wildlife species ever survive before the introduction of cattle on the ranges? Since when has cattle grazing ever been an effective tool to minimize erosion? Are wildlife densities considered to be so low that cattle must fill in the niche and help to graze down the forage.

It seems that such an effort is made to justify use of the forest as rangeland that absurd claims are being presented as to the beneficial effects to the entire ecosystem through cattle grazing. Cattle will promote nutrient cycling, material cycling, and water cycling, increase plant diversity and density, increase wildlife numbers, stabilize riparian zones, increase the productivity of streams (DEIS-IV-52 to 56), increase water quality and water yield (DEIS-III-140), and reduce compaction of soils. This effort to find ecological justification for any management goal, regardless of the well-known abundant detrimental effects, is a specious use of science. These fallacious arguments are supported by the presumptuous thinking that every action of the ecosystem must be managed or altered for its own benefit. It is stated that wildlife habitat can be managed through use of vegetation manipulation, grazing, and prescribed fire. Why would everything need manipulation? It would seem that grazing on transitional range unnecessarily prolongs revegetation after clearcutting by cattle damage to seedlings. It is never demonstrated how conditions (cattle numbers, forage condition and production) on rangeland of the WNF compare with those in any studies cited. Although some of the beneficial effects of cattle might qualify as anomalies or novelties, they should not be taken as generally applicable unless heavily supported since they are counter to the majority of literature and experience. With assertions as far reaching as those presented for effects of cattle, the mechanisms should be thoroughly presented mathematically and should be well-documented, using more than one reference to support any claim. Range was not even a category for information needs in the Plan (II-68). Apparently a few disjointed references sum up all that is needed to justify increasing AUMs.

Since FORPLAN operates on certain tables relating cattle and wildlife numbers to forage production and projecting a multitude of effects on other components of the environment, there is no reason why most of the relationships for cattle and wildlife cannot be quantitatively expressed. This treatment would eliminate the questionable scientific assertions made. There is no indication which of these dubious effects is entered into the

model for range calculations.

As part of the quantitative explanation of cattle/range effects, it could be more effectively explained how there will be an improving trend on 85% of the range in alternative C and only 30% in alternative A by 2030 when grazing is decreasing in alternative A and increasing in C. This should also explain how a 20 to 30% increase in big game will occur in one decade in alternative C. The outputs of various alternatives become shrouded in a cloak of unsupportable range science and relationships plus the mysteries of a FORPLAN run. Part of the deception in presentation of the alternatives is the way that otherwise reasonable proposals are invalidated through a set of hidden baggage which makes them unacceptable. For instance, alternative A is the only alternative which offers continual small reductions in grazing through the 5 decade period. This plan would be feasible were it not crippled by limiting funds for range improvements and stipulating that only continuous grazing systems would be used. Why is there not an alternative with decreasing AUMs which is not so easily dismissed? A real lack of funds for range improvement does not go hand-in-hand with the decreasing AUM scenario. Range improvement funding for any alternative is surely not financed by grazing fees so these funds might as well be provided by WNF budgets. Why make grazing systems unequal among alternatives except to make certain of them unacceptable. Range managers know which system provides the best protection for a given allotment. The real question is how high should permissible AUMs be and still meet other environmental obligations. The WNF Plan simply sets up straw men and invalidates all but the desired alternative. Why is there only one alternative which reduces AUMs?

Another example of faulty planning is found in timber/fish management. Increasing timber harvest is linked to increased generation of K-V funds which can be used in habitat rehabilitation which will lead to increased fish production. If present stream habitats are simply protected from timber harvest activities how much increased fish production would there be? Why is it again that only management (building of structures) is able to provide the stated benefits? Are habitats in streams so degraded that structures are the only solution? It seems strange that the best hope for the fisheries is to remove the timber on the watershed in the hopes of generating funds which may or may not be released to build structures. This scheme might read "destroy it in order to save it."

It is difficult to determine the real effects of timber harvest or AUM levels when so many mitigating or corrective factors are applied. For example, what is the real correspondence between alternative C and E. Alternative E has the best fisheries production but \$200,000 of appropriated funds are budgeted for fisheries work. Is such a budget feasible in reality? What would be the effect of increasing the appropriated funds in alternative C? Why was \$25,000 chosen as an appropriate level of funding and not \$100,000. It would be nice to know

whether the fisheries benefits in alternative E primarily derive from the reduced timber harvest or the fisheries budget. Dismissal of alternative E might easily be caused by varying the costs of uncertain mitigating coefficients and appropriations among alternatives with consequent results on the PNV rather than really observing the benefit of decreasing timber harvest.

The effects of grazing on fish bearing streams is not known on the WNF (DEIS-III-140). There are 938 miles of fish-bearing streams on the WNF and 56 miles of them are in present allotments. Alternative C will add new allotments and increase grazing by 10 to 20% (DEIS-III-68)(or 10 to 15%, see Plan III-8)(or 10 to 12.5%, see Plan-IV-52) in the first decade. At the same time, there will be over 70% more miles of fish-bearing streams in allotments after the second decade. Why are new allotments chosen to provide such a substantial increase in effects to fish-bearing streams when the effects are so poorly known?

Competition between livestock and big game can be reduced or eliminated (DEIS-IV-52). Is competition being eliminated through forage allocations and location of allotments? It would seem not. The WNF has 10 to 20% of the winter range available to wildlife in the area (DEIS-IV-52). However, approximately 50% of the WNF winter range is within commercial livestock allotments (DEIS-III-140). With most winter range being located on private land, it would seem that wildlife would be forced to survive on winter range grazed down by cattle during the summer and fall.

As for inter-and intra-specific competition in big game it "can only be controlled by... hunting" (DEIS-IV-52). These statements again deny any capability of an ecosystem to regulate itself. Why neglect the effects of natural predators or food supply to regulate the populations.

STANDARDS AND GUIDELINES

Forest-Wide

An average of at least two dead and down tree segments per acre (12 inch diameter, 20 foot length) will be left after timber management activities on a site (Plan IV-90). What reference can be cited to substantiate this as an adequate minimum? A review of down wood in old growth forests in Region 6 showed that 31 to 265 tons per acre can be expected (Maser and Trappe 1984). One study reported 121 fallen trees per acre in various decay classes. Considering the importance of fallen trees to maintenance of wildlife habitat (95 species depend on this material, see DEIS-III-39), establishing such a low minimum level can only mean that wildlife numbers will decline. What projected down log level in managed areas was actually used in projection of future wildlife population numbers?

Minimum hard snag requirements per 100 acres for primary cavity excavators will be set to the 60% level (presumably of Thomas 1979). Why is the 60% level established as a good level and what is the present wilderness and non-wilderness average for the WNF? Why does the Plan (IV-90) say only "favor" retention of snags with sign of excavation? Are there plans to remove snags with no present sign of excavation so that snag levels can be reduced from 100% down to 60%? What will be the future diameters of timber produced on these same sites? Will they be large enough to assure future snag recruitment of the larger size classes necessary for certain wildlife? How many green trees will be left on clearcut sites to provide snags or down logs during the period of regrowth? Why is deference shown to the customary method of timber operators to fall all snags? Will this be allowed? It was also customary to fill stream channels with slash and to fall trees downhill.

On winter range it was advised to "consider" short-term roads (Plan IV-91). Because the density of all road types, including local and work roads, which are established through harvest activity is much larger than that recommended for reduction of harassment to wildlife, the requirement for road closure after use should be much more stringent. What will road densities be on logged areas in the various management units after termination of the harvest activity? Because long-term plans for watersheds typically involve cumulation of road miles, road densities reported should not dilute the average by adding in unroaded area outside the management area.

Summer range should have well-distributed cover on 40% of a watershed (Plan IV-91). What is the average percentage cover on summer range undisturbed by past management? This guideline conflicts with that for timber harvest to leave at least 60% cover on watersheds of 1000 acres or more.

The guideline to minimize management activities on spring range "where possible" that would conflict with deer and elk and to provide abundant forage where possible is weak. Why does a more positive guideline such as this not also apply to summer/winter range? Also, how is deer and elk winter range protected by the summer/fall livestock grazing program? A non-structural habitat improvement for winter range was listed as livestock management (Plan IV-91). What is the evidence that livestock is a tool to improve diversity and abundance of forage at the densities prescribed for allotments?

Range

Problems of overuse of allotments or lack of forage are treated by expanding the allotment (Plan-IV-92). Another method which should be listed is decreasing permitted AUMs of livestock. The declining demand for beef nationwide, the minute amount of US beef contributed by national forests at great cost to the taxpayer and ecosystem integrity, the small number of ranchers who benefit from grazing rights on the WNF, and the breadth of

impact of grazing to the WNF add up to a general inability to justify maintained or increasing permissible AUMs.

The table describing allowable use by management intensity level on slopes of various hazard classes is hard to interpret (Plan IV-93). Why, for any soil-slope category, do the percentages not add up to 100%?

Timber

Silvicultural systems must promote stand structure and species composition which avoids risk of environmental damage (Plan IV-94). Does this mean that in replanting that a diverse mixture of tree species will be used and that selective harvest methods will be favored?

Riparian zone widths (Plan IV-97) appear to be reasonable except for the wet forest types on low gradient side slope areas. These areas are apt to be the prime anadromous or resident fish streams and consequently may need more extensive riparian areas to provide shading, litter and wood inputs, channel and bank control, and wildlife habitat. Widths of 75 to 100 feet would be a more appropriate base level. Are riparian widths on side slopes of greater than 70% meaningful; that is, what is the maximum hillslope gradient for which timber harvest is allowed?

A minimum of 80% of an activity area will be left in a condition of acceptable productivity potential for trees after land management activities (Plan IV-98). Does this degree of productivity reduction include that area tied up in permanent roads? Permanent productivity losses on other areas are not permitted by NFMA guidelines. Is loss of productivity from compaction not considered serious if it can be reversed in 100 years?

A minimum percent effective ground cover after cessation of logging must meet certain standards according to severity of erosion hazard (Plan IV-98). On low hazard surfaces a minimum of 20 to 30% ground cover is required and on very severe hazard land 60 to 75% ground cover is required the first year after disturbance. What differences in harvest practices would provide these varying levels of ground surface protection? How can a second year level of ground cover be required? What happens if vegetative recovery is not as rapid as planned? Why would timber harvest be allowed on sites of severe or very severe erosion hazard? No harvest is allowed on Class V soils (Plan IV-98). Is a Class V soil one with erosion hazard greater than the "very severe" class listed in the table?

Detailed soil surveys will be used "where available" in project planning (Plan IV-98). Since the general soil surveys were stated not to be adequate for project planning, what soil analysis will be used for project planning until detailed surveys can be made available?

Roads

Roads on the WNF will not be closed unless "it is necessary to protect or enhance National Forest resources" (Plan IV-105). What percentage of roads of different classes which are to be built will be closed to further traffic after an activity? Signing as a method of instituting road closures is impractical. What methods of road closure will be used?

PRESCRIPTIONS

EW-1 (Key Big Game Habitat)

The S+Gs for the big game habitat units state that range practices will "maximize the production of key forage species for big game." Here, as elsewhere in the Plan, there is the dictum that livestock will be used as a "tool" to benefit wildlife. This appears to be the worst kind of perversion of science and management by construing that the range and stream destruction from cattle grazing we have seen over the last century has been for the betterment of fish and wildlife. If cattle are the tool to maximize forage production for wildlife, then it should be shown that cattle only stimulate forage production and do not consume it, or it should be admitted that wildlife numbers are too low to provide the stimulation to production by cropping that has now been given over to cattle. In summary, production is not maximized for wildlife if a large part of it is taken by cattle. It needs to be well documented that cattle are a tool for improving quantity and quality of forage. Citing one study for such an important claim is hardly sufficient. Even if such a claim is substantiated, the WNF should satisfy the public that proposed AUMs fall within the limits set in these studies and that the WNF employs and enforces the same kinds of management strategies. It means little to prescribe frequent redistribution of cattle by herding when ranchers leave the cattle to inhabit the riparian zones all summer.

Why does the WNF state that created openings will be considered closed when tree heights are 6 feet in areas for deer and 8 feet for elk. Are the deer and elk areas so distinct? Thomas (1979) states that winter thermal cover for elk is 40 feet tall. The Wallowa-Whitman Forest uses 10 feet or greater as the height necessary to be considered closed. Although no more than 40% of any 1000 acre watershed may be opened, the 6 foot rule for "closure" means, in effect, that 80% of a 1000 acre watershed could be cut within two decades.

EW-2 (Riparian-Aquatic Habitat Protection Zone)

The goal of riparian zone management is to protect the distinct characteristics and resource values of this area (Plan IV-125). One of these unique characteristics is continuity of riparian vegetative cover. Although small clearcuts may not be the norm, why are they contemplated at all. The aquatic species which evolved in the streams of Region 6 experienced

predominantly canopied riparian zones. In the interest of providing an acceptable rationale for logging the riparian zones, managers of the WNF feel compelled to claim that logging will benefit the stream ecosystem. There now seems to be the myth growing that streams are really too cold or maybe too sediment-limited so clearcuts and slope erosion are effective management prescriptions. Sediment limitation is apt to be really a lack of woody debris to retain sediments. There should be an attempt on managed lands to design with nature rather than redefining ecosystem rules to correspond with management preferences.

What will be the "effective" rotation age for timber in riparian zones? What are the guidelines for age distribution of trees left in shelterwood cuts? Why is cutting necessary at all in the majority of riparian zones areas?

GF-1 through GF-6 (General Forest, variable timber investment)

These prescriptions represent a continuum from a tree farm utilizing predominantly clearcutting, thinning, fertilizing, and heavy replanting (GF-1) to managed wildlife areas with predominantly shelterwood cutting and low investment in silvicultural techniques (GF-6). The layout of S+Gs for these prescriptions confuse the issue (Plan IV-132 to 140). Do some statements apply to all prescriptions? What are the range S+Gs for GF-3 to GF-6? It seems strange that in a forest of 1,616,345 acres outside wilderness that only 126,756 acres emphasize wildlife management. On the GF lands, livestock grazing will favor timber production (Plan IV-133), yet livestock will be assured the full amount of forage allocated to it. On GF lands the interests of timber and range management seem to be emphasized. Wildlife needs will be met only to "the extent possible" in scheduling timber harvest. Protection to fish habitat or riparian zones were not listed in GF areas. Is it correct that management of these resources will follow forest-wide guidelines? Riparian planning is to achieve objectives of the area management (Plan IV-96). Does this mean that riparian management varies with the GF area objectives through which it passes, or are all class 1 and 2 streams considered equally regardless of the management unit through which they flow?

OG-1

Managing old growth areas on 260 year rotations is a reasonable timber management method which should be employed as much as possible. The primary difficulty with this method would be the intended rate of harvest. Will harvest rate over the next 50 years be at the sustained yield rate on a 260 year rotation? Also, how will roads be managed under this prescription? A fully roaded old growth area with full access to all road miles negates the benefit intended to wildlife dependent on old growth. Stringent road closures must be established for this area in particular.

The plan to salvage dead and dying trees in old growth areas is not in the interest of the wildlife which the old growth area is designed to protect. Recruitment of snags and down logs depends on a continual presence of dead and dying trees in the forest stand. Removal of these down to levels of "2 snags with at least 3 tons of down material (including 3 logs) per acre" (Plan IV-141) is irresponsible. When the number of fallen trees in an old-growth Douglas-fir stand is 121 trees/acre or more and up to 595 tons/acre, specifying minimum levels which are acceptable (and such minute levels) only leads to attempts to minimize the amount remaining.

RE-2 (Dispersed Recreation, Unroaded, Motorized),
RE-3 (Dispersed Recreation, Unroaded, Non-motorized)

The dispersed recreation prescriptions allow only salvage harvest. What method of salvage removal would be employed? Since "short-term roads may be constructed to protect adjacent resources" (Plan IV-154), would salvage to prevent spread of insects or disease be sufficient justification to build roads in an unroaded area?

Range management in these two prescriptions features Level C Management. This involves full utilization of forage allocated to livestock. While the objective of RE areas is supposed to be dispersed recreation, the predominant rights which appear in wording of the prescription favor livestock. Even trail reconstruction will be conducted in a way that favors forage production. While one might assume that wildlife will benefit from this, only the rights of livestock to forage are emphasized.

RM-1 (Intensive Range Management)

Allocation of forage for wildlife on the intensive range areas will be based on analyzed needs (Plan IV-161). Does this imply that if wildlife numbers decrease, that needs will be less? How have wildlife needs for forage been determined for the RM areas and will they be constant regardless of wildlife numbers?

WI-1 (Wilderness)

Level B Management will be implemented for livestock grazing on wilderness areas. Distribution is to be achieved through riding, herding and/or salting. How much riding and herding is actually used in wilderness compared with salting? Because fencing is not allowed in wilderness areas, what method is proposed to reduce use of riparian areas by livestock.

MONITORING PLAN

The adequacy of a Forest Plan depends to a large extent on the effectiveness of its monitoring plan. The monitoring plan for the WNF is given in Section V. Comments follow on the monitoring program.

Recreation

ORV use effects will be monitored through evaluation of public comments. Will independent evaluations of sites be made by Forest Service field personnel? What is the ORV approved monitoring plan? Why aren't the details included in the overall plan? For example, further evaluation will be done if unacceptable damage is done. What level of damage is taken as acceptable?

Wilderness

How is the carrying capacity of a wilderness determined? This would affect both the ability to protect the wilderness resources and the estimation of future adequacy of wilderness to meet recreational pursuits. However, this says nothing of the capacity of the wilderness acreage and spatial arrangement to meet the needs of wildlife and other dependent resources.

Wildlife

The integrity of OG-1 areas will be monitored by field counting annually the MMR sites and biannually other sites. What factors would cause the loss of these sites? If harvest activities are closely monitored, why would the old growth areas disappear?

K-378

Population trends will be monitored by reviewing WDGs data. Doesn't the WNF do any wildlife surveys of its own? Does WDG data cover all MIS species? Which MIS species are being used in the monitoring plan?

A habitat capability of 60% was established as the minimum for primary cavity excavators? What is the current habitat capability and how was the minimum established? The cost per survey is \$2000; how many surveys will be done? Since monitoring frequency is every 5 years, this is a critical point. How representative can a single survey be for the entire forest?

Population trends of elk, deer and mountain goats will be reviewed every 3 years, yet the standard for further evaluation is a population increase or decrease for 5 consecutive years. This guarantees that the conditions for reevaluation will not be met. If a long-term change is a necessary condition, how long is implied? If the WNF is only responsible for managing habitat for big game, why does it monitor game numbers? Does the WNF have the ultimate authority to regulate big game numbers by recommending hunting regulations to balance the AUMs allotted to cattle?

Spotted owl pairs are monitored every 3 years for \$23,400 and T and E species are monitored every 2 years for \$5000. How many T and E species are involved? Is spotted owl monitoring much more difficult or is monitoring of T and E species much less

extensive? Is monitoring of T and E species adequate to represent sensitive and rare wildlife which do not appear on the list?

Fish

Habitat capability for resident and anadromous fish will be measured at 9 sites annually. Physical data will be used to calculate smolt or resident habitat capability. Biological data will be collected by fisheries agencies. If a 20% change in fish production is detected by fisheries agencies what would be done? How long are the index sites and how representative would these be? Will monitoring also be done in relation to logging activities on specific sites? What fraction of sites receiving management per year are monitored for effects on streams in their drainages. Does monitoring include pre- and post-management sampling? If funds are not available for monitoring, will any management be allowed?

What is smolt habitat capability and how is it measured? What parameters are identified in the field as a guide to future smolt habitat capability?

Migration obstacles for anadromous and resident fish will be monitored by accounting for changes in percentage of culverts inhibiting fish passage. It would seem that culverts inhibiting passage should be examined individually rather than as changes in percentage. Culverts on high priority anadromous streams should be repaired immediately. If new culverts are installed using improved techniques, the threshold of a 10% change in problem culverts in 5 years will not be reached even though the number of these problem culverts may remain the same. That is, the percentage of problem culverts declines as the number of high quality new culverts increases.

Range

The capability to produce planned AUM outputs will be monitored and a 10% change in projected AUM outputs would require reevaluation. What is the AUM output? Does it have anything to do with beef production or is it simply the number of cattle which grazed range on the WNF? Permitted AUMs appear to be a constant from year to year once the Plan is adopted. Why is annual forage production not evaluated on index allotments to provide data for mid-season adjustments in permissible levels of livestock. The term AUM is supposedly an index of available forage but when there is no monitoring yearly of forage production under varying climatic conditions, a fixed level of permitted AUMs would lead to damaged range in dry years. If cattle receive only a maintenance ration in dry years, they can be fattened up back on the ranch but wildlife must bear the consequences of overgrazing.

Allotment Management Plan objectives will be compared with Prescription Guidelines. When new allotment plans are written,

if guidelines are not being met, then action will be required. How often are allotment plans rewritten; how often are EAs done on an allotment? Which factors are the key ones to be evaluated when checking for compliance with guidelines?

The availability of transitory range will be evaluated annually by measuring AUMs. Why does the forest count so heavily on transitory range to supply forage when such a small percentage of total forage comes from it? Why is \$3500/yr spent on this activity when it is obvious that range is available after a clearcut? While \$3500/yr may not be a great amount of money to evaluate the forest, it seems extraordinary in comparison with the amounts spent to evaluate stream conditions.

Each allotment will be evaluated for trend, condition and production every 10 years. Four allotments will be studied per year. A trend could be established for only 4 allotments within any given planning period, at best. A 10% increase in acres of downward trend per allotment will initiate further evaluation. Does this mean that degradation of 9% per decade would be allowed? What would be done if a deteriorating trend is established? Considering that precision for range condition estimates is moderate, and a 9% reduction in condition was detected, is no further evaluation needed?

Timber

The annual and decadal timber sale program will be compared with 5-year plans and accomplishment reports on a board foot basis. What happens if 25% more timber is cut one year than was projected? Is there a determined effort to reduce the following year's cut by 25%? Is there basically no problem in allowing a 10-year harvest which is 10% greater than the ASQ?

Restocking of cut sites within 5 years will be assured. What minimum stocking levels are assumed for various species? What happens if a planted site does not meet minimum levels? Is there an obligation to replant sites on which previous planting efforts have failed? How have data on replanting success been used in scheduling timber harvest on sites on the WNF? That is, are there any combinations of slope, aspect, altitude, soil type, and annual precipitation which dictate special harvest restrictions or deny harvest at all because of regeneration problems?

Harvest is allowed only when the stand meets the CMAI requirement. What are the practical implications of this requirement? That is, is there a minimum age or a minimum volume requirement to be attained, or both? How does site productivity variation affect the age of first entry or clearcutting? Answers to these questions are pertinent to understanding the projected times between disturbance of future timber stands.

A fairly low emphasis is placed on determining timber yield tables (\$3000 expended once in the planning period). Since the

prediction of L_{TSY} hinges largely on the accuracy of the timber yield tables, it would seem that more emphasis would be placed on these studies. How accurately is timber yield known for the multitude of site conditions on the WNF? What are the variations involved and how are prescriptions matched with yield table information for a given site?

Water

The effectiveness of applying BMPs will be monitored on 10% of Project activities to assure compliance with state water quality standards at a cost of \$68,950/yr. The Water Quality Monitoring Plan lists variables to be monitored. Where is this plan described? The amount budgeted for this activity indicates concern for meeting the obligations to provide good water quality.

Cumulative effects on water quality and water yield will be assessed for major basins in the WNF. Are any data available at present which would act as the standard by which to evaluate deviations?

Vegetation components in the riparian zone will be monitored on 16 sites at 1 and 5 years after completion of the management activity. How will the sites be chosen? If more than 20% of the area has exposed soil after the activity, what could have been done during the activity to prevent this? How often will clearcutting be used in the riparian zone for tree removal?

Soil

Soil productivity will be monitored by evaluating 10% of all tractor logging units for percentage of area affected. If more than 20% of an activity area is compacted, reevaluation will be necessary. What degree of compaction is required? Will actual measurements of degree of compaction be made or will it be assumed that any paths of heavy machinery will cause compaction? Are cumulative effects of past management accounted for in these area estimates?

Soil erosion losses will be measured one time following completion of an activity from 1% of logging activity areas and road construction sites. If soil losses exceed 10 tons/acre/yr while the project is active, the activity will be reevaluated. What kinds of soil losses have been found in the past for various combinations of soils, slopes, and logging practices? Since acceptable soil loss varies with slope, why is 10 tons/acre/yr an acceptable standard for all slopes? Such a level would be extreme for shallow soil areas on steep slopes? What percentage over natural erosion levels does this represent for various conditions?

Soil productivity will also be measured on 6 dry and 14 wet pairs of forest sites by determining tree growth. Forty sites total per year will be evaluated. If growth rates are not equal

to or greater than yield table values of managed stands, the site will be reevaluated. Are the appropriate yield table estimates minimum values for the sites? If a site does not match the table value, will it then be assumed that the site is really different than those for which the table was created? How extensive is the present system of classification of sites and tabulation of yield estimates? What role does the monitoring program have in refining the tables? What would be done if growth rates seem too low? Does the monitoring program include plans for determining possible reductions in productivity of second growth of managed vs. natural succession on a given site type?

Accelerated mass wasting will be monitored when it threatens significant resources. What evaluation is planned for numbers and surface area of mass failures which may reduce productivity but not directly threaten other resources?

Mining

The adverse environmental impacts of mining operations will be continuously evaluated by reconnaissance surveys of compliance with operating plans at an annual cost of \$2,100. What are the standards for instream compliance; what will be measured? It would seem that this type of monitoring is superficial at the cost and using the methods listed. How much water quality monitoring is the mining company responsible for?

The number of active claims will be monitored continuously. A 10% increase in activity within a management area will initiate reevaluation. Within what time period will this increase be evaluated? Is there a threshold level of surface disturbance in terms of area or magnitude of delivered sediment which should not be exceeded?

The reasonableness of cost to mining operators for implementing their management plans will be assessed. Although costs of operating must be considered by mining companies before undertaking an operation, why is it the responsibility of the Forest Service to assure them that any activity may be conducted at a profit. If safeguarding the environment costs a certain amount, why must an operating plan be watered down so that costs to the operator are less than costs to the environment?

CONCLUDING REMARKS

The WNF has done a remarkable job in assembling a great deal of data and presenting it clearly and completely. There seemed to be few internal inconsistencies. The sections on interactions of major resource components were helpful and provided a good means of assessing the state of knowledge in various areas. Many good literature references were given but in many cases much more complete substantiation of management plans should be provided through literature reviews. We appreciate the candor of the WNF in listing the extent of informational needs rather than trying

to hide these in verbage. Greater ability to deal with the mass of data presented in the three volumes of the Plan could have been achieved with a more extensive Table of Contents and an Index. A great deal of searching was sometimes necessary because of the lack in this area.

We especially appreciate the extensive recognition of and reference to the unique relationship that exists between the Forest, the Yakima Indian Nation, and other affected tribal groups. In no other forest plan that we have reviewed has the Forest Service' obligation to meet treaty rights been so plainly acknowledged. This awareness by Wenatchee National Forest is indicative of the progressive management philosophy we often encountered during our review of its documents.

In describing each variable to be monitored it would have been very helpful to cross-reference specific standards and guidelines so that precise criteria could be associated with monitoring variables. From standards and guidelines, references could also have been given to literature citations which support the use of certain environmental criteria. This format could possibly better integrate the components of the Plan. It is often unclear which of the many relationships between resource components are actually used in modeling outputs. These should be more rigorously elaborated.

We feel that the best of management intentions are frustrated if standards and guidelines are inadequate and the monitoring program is weak or poorly funded. The present lack of information about many resources (e.g. fisheries, fish habitat, riparian zone conditions) makes real management difficult if not impossible until this information is collected. It appears to be the intention of the WNF to continue as usual in the interim hoping for the best using existing management practices. It should be a priority to collect needed information for management as rapidly as possible. In the absence of these data, fish habitat management should concentrate on stewardship of the resource. After all, there is a mandate to protect fish and wildlife habitat and no law which requires the WNF to log its forests. Monitoring needs to be emphasized to establish baselines from which to evaluate future trends and also to improve models of sediment yield. Monitoring funding should be attached as line items in the timber budget. No timber harvest should be allowed if the funds for monitoring are not available. No watered down version of an adequate monitoring plan should be accepted if funding is limited.

More expanded explanations of our position on monitoring are provided in the Appendix. First, there is a general consideration of the question. Second, there is an example of a monitoring scheme that should permit multiple-resource management.

If you would like further information regarding our interpretations of the Wenatchee National Forest plan, please

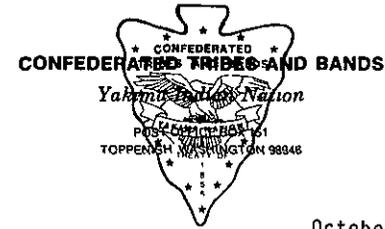

feel free to contact any of our staff, Jim Weber (policy assistant), Alex Heindl (biologist), or Dale McCullough (biologist) at (503)-238-0667.

Sincerely,

S. Timothy Wapato

Dear Sir,

Attached is the Yakima Indian Nation Wildlife Resource Management Program's review of the Proposed Wenatchee National Forest's Land and Resource Management Plan.

The review selects an alternative, however, qualifies itself by stating none of the alternatives adequately address the Yakima Indian Nation rights under the Treaty of 1855.

The Yakima Indian Nation recognizes the fact there is a wildlife resource interchange between the Yakima Indian Reservation and the Wenatchee National Forest containing the Ceded Area. The Yakima Tribe, through our Wildlife Program, is trying to preserve and enhance this wildlife resource and would hope that the caretakers of the Wenatchee National Forest would do the same.

Sincerely,

Harvey E. Adams

SUBJECT Comments on the US Department of Agriculture, Pacific
Northwest Region's Wenatchee National Forest Proposed Land
and Resource Management Plan, Draft Environmental Impact
Statement

K-382

A large portion of the deer and elk herds that summer in the Tieton River Basin winter on the Yakima Indian Nation's Toppenish Creek Game Preserve and adjacent tribal lands. These herds provide an important natural food source for the Yakima Indian people. While the tribe has allocated large winter range areas to conserve this resource, the ultimate success of these animals depends on the land management practices on the summer range by the U.S. Forest Service. This illustrates how forest activities within the Wenatchee National Forest impact the wildlife resource within the Yakima Indian Nation's boundaries. In addition, the Wenatchee National Forest represents a large portion of the Yakima Indian Nation's ceded area. The Yakima Indian people retain basic treaty rights with respect to the wildlife resource within this area.

In the short time we have had to review the proposed Wenatchee National Forest plan, we have become aware of some major faults in the development of all the alternatives. We will briefly outline our concerns relative to the alternatives and then select an alternative to meet the wildlife resource treaty right needs of the Yakima Indian People.

The alternatives were developed from the "issues and concerns" of public opinion. This information was to serve as the data base for analysis of the major issues and concerns and subsequent alternatives were developed to reflect these issues and concerns. The compiled information was fed into a computer and the analysis was completed using a program called FOREPLAN. This is pointed out in the Draft Environmental Impact Statement, (DEIS). What the DEIS fails to point out is that the assumptions about the value of each of the resources represented as an issue and concern was established by the 1980 Resource Planning Act (RPA) program. The RPA was revised in 1985. Using each of these RPA assumption sets, 2 versions of FOREPLAN were developed. A mix of these two versions was used in preparing the Proposed Land and Resource Management Plans in the Pacific Northwest Region.

What is not clear in the Wenatchee National Forest Proposed Land and Resource Management Plan DEIS is what sort of mix was used. Although the 1985 RPA was a refinement of the 1980 RPA, in his Review of the 1985 RPA Update, O'Toole (1984) states RPA was systematically and deliberately biased towards timber, grazing and other market resources, and away from non-market resources such as fish, wildlife, and recreation. The up-shot of this is that the assumptions used in the economic values of the relationships between timber and other resources are suspect.

K-383

To look for a preferred alternative that would reflect the needs of the natural environment and yet protect the social and economic environment, the public was invited to use a document called, "Reviewer's Guide and Response Form". On page 42 of that document is a table under the heading "How the Alternatives Respond to the Issues". Here is where the assumptions of the RPA are put to use in comparing the alternatives in terms of their market and non-market resources. Nine major headings summarize the major issues and concerns. It does not take much time to examine the unit values for each alternative associated with each of the 9 headings and to conclude that Alternative B and Alternative E are at opposing ends of public forest management philosophy. Alternative B has the greatest non-market resource costs and the greatest market resource benefits. Alternative E has the least non-market resource costs and the least market resource benefits. In fact Alternative E under "Social/Economic unit values for "Change in employment and "Change in income have lost market resource values. Under Alternative A the truth is born out. This alternative is the No action, current management

direction for the forest alternative. Yet, we see in the table that a loss is projected for the next decade for market resources. These two items are very emotional and by using a deceptive "change method of calculating their value, emotions can reach even higher levels. Again it should be pointed out that the bias of the RPA allows for this kind of data confession.

In recognition that the informed public might see part-way through this kind of manipulation, the Forest Service moderates and chooses to come down just off-side of the middle of the fence and yet in favor of a market resource alternative, Alternative C. The hoopla thus pits the environmental and timber industry folks against each other and yet stacks the deck in favor of the timber industry.

In each of the alternatives the cost to the taxpayer to harvest timber is greater than the return from the sale of the timber. The amount of tax dollar loss varies greatly depending on the alternative and it would seem that the percentage of the loss returned from timber also varies greatly. The net percentage the timber industry will realize does not vary greatly and remains about 80% in each alternative. The net amount the timber industry realizes under each plan does vary greatly. Again, we see the magic of the RPA at work.

In short, the economic burden is not fair to the taxpayer. The environmental burden is not fair to the tax payer. The tax payer is going to support the timber industry at a fixed rate in each alternative, and be expected to pay different rates for different degrees of environmental degradation. The less the environmental degradation the greater the rate to the tax payer.

All alternatives fall very much short of protecting the needs of the people by penalizing them for their needs. All alternatives contain elements that damage the natural environment in one way or another and yet protect the timber industry. However, because the Yakima Indian people have charged the Wildlife Resource Management Program with preserving, protecting and enhancing it's wildlife resources within boundaries of the reservation and in the ceded area, we support the adoption of the most environmentally sound plan, Alternative E. Under this alternative there is limited room for the Federal Government to keep it treaty promises for the protection of the wildlife resource needs of the Yakima Indian People. Without that protection, the resource is not managed to meet these needs. In short, this alternative falls short of meeting those needs and penalizes

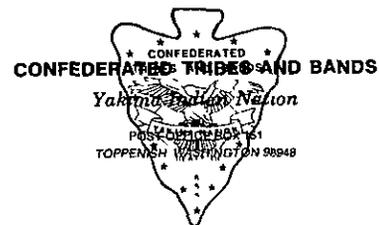

the american tax payer to the greatest extent. However, all other alternatives fall even shorter in meeting these treaty right needs. Alternatives F and G are the more moderate environmental plans. Each contain the attractive elements of E, but in less abundance. Each also contain more of the unattractive elements of the least environmentally sound plans.

In every plan the issue of human recreation varies from the least environmentally destructive to the most destructive forms. Some are compatible with wildlife, some are not. Vehicle use oriented recreation is the most limiting for wildlife habitat use. Preserving an area for its scenic value such that it can be viewed from a car, snowmobile, or dirt bike might be pleasing to the eye if you don't miss seeing the deer and elk that will be absent from your view.

Although most desirable, alternatives E, F, and G contains a management area type near the northern boundary of reservation lands that will surely cause problems for the Yakima Indian Nation. The RE-2B designation allows for off-road vehicle use. The opportunity for trespass on tribal lands is very great. If recreation in this area is a strong issue of concern, the RE-3 would be more compatible with adjacent land owner use. It would be best to include the entire North and South Fork of the Tieton drainage as EW-1 to be managed as summer range for deer and elk. This would compliment the YIN's management of its extensive winter range areas.

MEMORANDUM

TO
THROUGH

Mel Sampson, Tribal Chairman
Carroll Palmer, Director of Natural Resources

FROM
DATE

Cultural Resources
30 Sept 1986

A major legal and conceptual problem with the Wenatchee National Forest Management Plan lies in its failure to recognize responsibility for all of the resource rights retained by the Yakima Indian Nation under the Treaty of 1855. Interestingly the Management Plan (Proposed Land and Resource Management Plan, Appendix C-1) indirectly recognizes Article 3 of the Treaty of 1855

This right includes consideration by the Forest Service of the environmental effects of their land management activities on the water quality and anadromous fish habitat of the Forest.

The Management Plan does not mention a United States Forest Service consideration of the other resource rights specifically reserved in Article 3 of the 1855 Treaty with the Yakima Indian Nation

The exclusive right of taking fish in all the streams, where running through or bordering said reservation, is further secured to said confederated tribes and bands of Indians, as also the right of taking fish at all usual and accustomed places, in common with the citizens of the Territory, and of erecting temporary buildings for curing them, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land

As a basis for evaluating and planning future land use alternatives, a management plan which does not consider rights

Wenatchee National Forest
P.O. Box 811
Wenatchee, WA 98801

Dear Sir

Attached is the Yakima Indian Nation's archeological and cultural review of the Wenatchee National Forest's proposed Land and Resource Management Plan.

As you will see, no alternative presented was chosen. The Archeologists retained by the Yakima Nation reviewed the proposed plan and have raised valid concerns which are supported by the Yakima Tribe

It is the desire of the Yakima Nation that the caretaker of the Wenatchee National Forest recognize the Yakima Nation's inalienable rights as presented under the Treaty of 1855.

Sincerely,

Melvin R. Sampson
Melvin R. Sampson, Chairman
Yakima Tribal Council

K-365

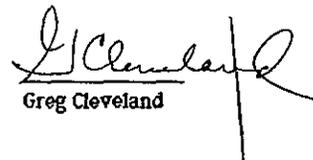

grazing, wilderness, recreational, etc do in fact have a significant impact on archeological sites and traditional use areas. The Wenatchee National Forest Plan tacitly admits in its Reviewer's Guide that Cultural Resource inventory and evaluation (archaeological sites only) is directly tied to timber harvest. The Yakima Nation feels many of the archeological sites outside of these timber harvest areas, mute testimony of past use are being destroyed. Furthermore this narrow approach has made no meaningful attempt to inventory and evaluate traditional use areas.

In summary, Cultural resources are more than archaeological sites within the Yakima Nations Ceded Lands. The Wenatchee National Forest Management Plan fails to recognize and then utilize the established legal rights of the Yakima People as a basis for land use planning. Because from a Cultural Resource perspective the Management Plan promulgates certain specious legal fictions we are unable to support any of the land use alternatives until the Treaty of 1855 is realized as the *a priori* planning document.

K-386

Morris Leo Uebelacker, Ph.D

Greg Cleveland

which were reserved by the Treaty of 1855 is a legal fiction. In the view of the Yakima Indian Nation, the Treaty of 1855 puts legal incumbrances on the land which are determinable, compensable, and real property and as such must always receive *a priori* consideration in planning. Clearly the Wenatchee National Forest Plan inadequately addresses the Treaty of 1855 which should serve, in effect, as the primary legal mandate for planning.

The Wenatchee National Forest Plan sets forth a variety of alternatives for the management of a major portion of the Yakima Indian Nations Ceded Lands and by virtue of proposing various land uses, it directly effects the resources to which the Nation reserved rights. We find no land allocations of traditional resource areas and no discussion of how these various land use categories will affect the Nations reserved resource rights. This is a major oversight particularly in the Draft Environmental Impact Statement. Although the impact statement addresses known archeological sites distributions in a general way it fails to recognize these places as indicators of customary use.

Further the Management Plan fails to recognize that the contemplated land use alternatives limit access and use of these traditional places and resources by mixing incompatible uses. For example, recent rehabilitation of anadromous fisheries brought about by the aggressive planning and cooperative maneuvering of Tribal and other Fisheries Biologists revives the necessity for maintaining access to the usual and accustomed places guaranteed by the Treaty. While many of these Places are now developed without regard to the reserved rights of Yakima Indians, the Forest Service must recognize that with this rehabilitation of the fish runs, the Forest Service must plan for a return of Indian fisherman. Which management alternative allows and recognizes traditional use areas? Which management alternative allows space and access for this land use?

The Cultural Resource Program should define and inventory traditional use zones and archeological sites independent of timber harvest activities. Other uses e.g. motorized vehicles,

Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, Washington 98807

Dear Friends:

Thank you for contacting my office to express your concerns about the Wild and Scenic River legislation I plan to introduce late this year. I apologize for the delay in responding. My staff is still in the process of gathering information about Washington's rivers and as a result I have not assembled a list of proposed rivers for inclusion in the legislation. Your views about the Wenatchee River are helpful to me in this process. I want to work closely with the rest of the Congressional delegation, local government officials and citizens like you as I develop this bill. Accordingly, I appreciate having your views and look forward to working on this issue with you.

I am acutely aware of your concerns regarding the effect of this legislation. Many landowners are particularly worried about the possibility of condemnation. One of my foremost goals in designing this legislation is avoiding condemnation. That was also the intent of the original Wild and Scenic Rivers Act of 1968. To date, more than 200,000 acres of land have been designated along Wild and Scenic river corridors in Washington, Oregon and California. None of that land was acquired through condemnation.

There are many landowner protection provisions in this Act which illustrate Congress's intent to protect private landowners from federal acquisition. For example, the Act prohibits the condemnation of a fee interest in land if fifty percent of the corridor is already in public ownership. Most rivers under consideration in Washington will fall into this category.

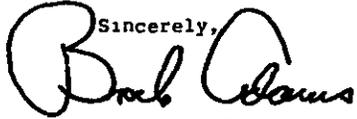

I hope this letter begins to address some of your very valid concerns. I am enclosing the answers to a list of commonly asked questions regarding Federal Wild and Scenic designation. Because of your interest, I will also forward a copy of a brochure on Wild and Scenic designation from the Forest Service and National Park Service when it becomes available. If you have any further questions or comments please contact Jim Gunsolus in my western Washington office at (206) 442-5545, Dave Gallick in my eastern Washington office at

QUESTIONS AND ANSWERS ABOUT THE WILD AND SCENIC RIVERS ACT

Q What is the Wild and Scenic Rivers Act?

A. The Wild and Scenic River Act was adopted in 1968 (Public Law 90-542) to protect free-flowing stretches of rivers throughout the United States. The Act seeks to protect and continue the types and intensity of use that exist at the time of designation. Not all rivers are eligible for designation. Only those free-flowing stretches with exceptional natural, cultural, recreational, geological, fish and wildlife, historic or scenic values are considered.

Q Why do these rivers need to be protected?

A. Rivers are one of Washington state's most precious natural resources; they are also one of the least protected. One hundred years ago, when Washington entered the union, there were 8,250 miles of free flowing rivers. These rivers supported bountiful salmon runs and provided clean water to a growing population. Since that time nearly one-sixth (1,300 miles) have been altered by dams, diversions, channelization or pollution. While no one denies the benefits of harnessing some rivers for electricity, irrigation or industrial development, we need to ensure that other rivers remain in their natural condition to provide the benefits of fisheries, water quality, recreation and wildlife habitat.

We are still in an excellent position to preserve and manage these resources for the future. The Wild and Scenic Rivers legislation gives us a tool to begin this process. However, unless we get this process underway we risk losing more rivers and the land bordering them to unplanned development.

Q. How does the Act work?

A. The Act accomplishes its goal in two major ways. First, it prevents new dams and major water projects from being built on designated river segments. Second, the Act helps protect the river or river segment by allowing for management of the land an average of one-quarter of a mile on each side of the river.

A river may be protected through three different classifications. The appropriate designation depends upon the current status of the river. These classifications are "wild", "scenic", or "recreational." A river may be classified entirely under one category or different sections of a river may be designated under

In order to qualify for a "WILD" classification, the river must be accessible only by trail with no development along its banks. Every river segment in Washington that is being considered for this classification is entirely on public land. A "wild" classification means that no road building or ongoing timber harvest will be allowed in the one-half mile river corridor. Grazing may continue as long as it is managed in a manner which doesn't damage the river's outstanding qualities.

A "SCENIC" river is one that is currently accessible by road. It may already be bridged and have a few homes on the banks. The purpose of scenic classification is to retain the natural characteristics of the river. If a river is classified "scenic", large clearcuts within one quarter mile of the river would not be allowed. However, selective logging and small clearcuts would be permitted. Farming activities generally are not restricted as long as they do not disturb the river's outstanding qualities.

The last category is "RECREATIONAL". This category includes river segments with some housing, industrial or commercial use along it. In these areas timber harvesting and agricultural practices are basically unaffected. These activities may continue as long as they do not cause erosion or destroy the view along the river. The purpose of recreational classification is to allow the agencies that manage the land to coordinate plans and to control adverse development along the river bank.

In Washington state, the Skagit River is an excellent example of the successful application of the federal Wild and Scenic Rivers designation. Included as a study river in the original 1968 legislation and designated in 1978, the mainstem of the Skagit was classified "recreational" and the tributaries "scenic."

Q. When can private property be condemned?

A. Federal agencies avoid condemnation whenever possible. It is slow, costly, and politically unpopular. No property in Washington, Oregon or California has ever been condemned for Wild and Scenic River designation.

The Act includes specific protections for property owners. Condemnation of all property rights (fee interest) is prohibited if more than 50% of corridor land is publicly owned. Most Washington rivers which may be considered for designation are more than 50% publicly owned.

Q. When will the government purchase a "scenic easement"?

A. While condemnation for fee title is prohibited in most cases, the government may purchase "scenic easements" or development rights. For example, if the management plan determines that the best use for a particular segment of land is to retain its natural appearance and not allow logging, a payment must be made to the landowner to compensate for not cutting the trees. The landowners retain full title to the land: they may sell it, rent it, leave it to their heirs and restrict public access. The government cannot prohibit a landowner from harvesting timber without just compensation. Often landowners resist scenic easements prior to designation and later, once they understand the system, request that a scenic easement be purchased.

Q. What effect will designation have on property values?

A. In recent studies on two Wild and Scenic Rivers, the Upper Delaware and the Rogue, property values in the designated corridors were shown to increase at a higher rate than those for adjacent lands. Realtors on the Upper Delaware frequently cite the designation in sales listings.

Q. What effect does designation have on agriculture?

A. Because Wild and Scenic designation preserves rivers in their current state, it does not affect existing water rights. Existing irrigation systems are not disturbed. Alterations to existing systems and new water projects are allowed as long as they do not have a "direct and adverse effect" on the attributes which made the river eligible for Wild and Scenic designation. In practical terms, this means smaller methods of providing for water supply such as small diversions or conduits that are wholly private, local, or state projects will not be affected.

Q. How is a river designated under the Wild and Scenic Act?

A. First, information is gathered about various rivers in Washington. This information comes from a variety of sources including interested citizens, governmental agencies, community leaders, power planning groups, industry organizations and environmental groups. As soon as that information is compiled, a draft list of rivers will be released for discussion purposes. There is no list at this time. After these comments are considered, the revised list will be incorporated in a bill format. This bill will not be introduced until citizens and organizations have been given ample opportunity to express their

Q. How can citizens become involved in the process?

A. Ideally the river protection program should be designed by interested organizations and citizens that care about the future of individual rivers. There will be a number of opportunities for citizens to participate. Before a bill is introduced, interested persons should send comments or suggestions regarding specific sections of specific rivers. After the bill is introduced, field hearings are expected to be held in the state to listen to citizen concerns. They are an excellent opportunity to participate in the process. Later, citizens will be encouraged to become involved in the development of a management plan for the river. Meetings will be held and written comments received to formulate this plan. After the final plan is approved, there is also an appeals process if persons feel that their concerns have not been sufficiently addressed.

REPLY TO
ATTN OF

WD-136

Sonny J O'Neal
Forest Supervisor
Wenatchee National Forest
P.O Box 811
Wenatchee, Washington 98801

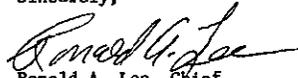

Dear Mr. O'Neal:

In accordance with our responsibilities under the National Environmental Policy Act and Section 309 of the Clean Air Act, we have reviewed the Supplemental Draft Environmental Impact Statement (SDEIS) for the Land and Resource Management Plan for the Wenatchee National Forest. This SDEIS evaluates a new alternative, Alternative NC (No Change), which was developed from the Timber Management Plans originally developed in the 1960's. It also evaluates rivers on the Forest for recommendation for classification in the Wild and Scenic Rivers System.

Alternative NC does not incorporate all the provisions of the National Forest Management Act of 1976 and would not include the specific standards and guidelines for water quality protection. As such, we could not support the implementation of this alternative.

We understand that the purpose of this SDEIS was not to address public comments on the DEIS. Since our September 30, 1986 comments on the DEIS remain outstanding the rating on the DEIS and SDEIS are the same. EC-2 (Environmental Concerns - Insufficient Information).

Thank you for the opportunity to review this SDEIS. Please contact Wayne Elson at (206) 442-1463 for any questions concerning our comments.

Sincerely,

Ronald A Lee, Chief
Environmental Evaluation Branch

Mr. Sonny J. O'Neal
Forest Supervisor
Wenatchee National Forest
P O. Box 811
Wenatchee, Washington 98807

Dear Mr. O'Neal

The Department of the Interior (Department) has reviewed the Supplement to the Draft Environmental Impact Statement (EIS), Proposed Wenatchee National Forest Land and Resource Management Plan. The following comments are provided for your use and consideration when preparing the final documents, and are supplemental to the Department's October 9, 1986, comments on the draft EIS.

GENERAL COMMENTS

The Supplement is generally adequate in portraying the predicted impacts from implementation of the no change alternative. It states that the Alternative NC will not fulfill the requirements of the National Forest Management Act with respect to fish and wildlife resources. The Fish and Wildlife Service (Service) concurs with this determination, and also considers Alternative NC to be environmentally unacceptable. On-the-ground application of this alternative would result in a heavy loss of important fish and wildlife resources and their habitats. More specifically, migratory birds, anadromous and resident fish, and important big game animals including deer, elk, and mountain goat would experience severe adverse impacts. Riparian habitat would be degraded, and the depletion of old growth forest ecosystems would be accelerated.

Because old-growth forest ecosystems, which provide optimal breeding and foraging habitat for several important vertebrate species, are scarce, the old-growth timber harvest issue is a major concern. The spotted owl is but one member of the rather unique and important animal community that depends on old-growth forests.

The interagency agreement signed on August 12, 1988, by the Director of the Service and the Chief of the U.S. Forest Service, commits the Forest Service to ensure the continued existence of a well-distributed spotted owl population throughout its National Forest range. Under the agreement, both agencies have agreed to coordinate efforts, including research and monitoring. An annual progress report will be supplied to the Service, and the agreement provides for emergency action if a viable population is not maintained. The final documents should refer to this interagency agreement. The terms of the agreement should be reflected in relevant sections such as standards, guidelines and monitoring.

The Forest Service recently released their Record of Decision regarding spotted owl management in the Pacific Northwest. This final decision and its potential effects on spotted owl populations of the Wenatchee National Forest should be addressed in detail in the final EIS. The Service is skeptical that the management alternative (Alternative F)

selected by this decision, in concert with the preferred planning alternative for the Forest, will result in maintaining viable spotted owl populations. This view is based in part on Forest Service plans to include an inadequate amount of suitable habitat for spotted owls.

The Service is concerned about the level of protection that will be provided for Federal candidate plant and animal species of the Forest. In meeting this objective, the Forest Service should fully coordinate with the Service in all planning endeavors and forest activities which might affect the candidate species. In some instances, this may necessitate intensive and continuing coordination efforts between the Service and the Forest Service. A case in point is the present effort of both agencies to protect the candidate plants Delphinium viridescens and Sidalcea oregana var. calva.

SPECIFIC COMMENTS

Page IV-8, paragraph 2: It should be noted that if forest activities have the potential to cause any adverse impacts to threatened or endangered species, the Forest Service would be required to formally consult with the Service under Section 7 of the Endangered Species Act.

Page I-15, 4th column, last block: Reference to the grizzly bear should be footnoted to the effect that the Washington State Department of Wildlife is presently conducting a five year evaluation of grizzly bears in Washington's north Cascades, including Wenatchee National Forest. The evaluation is funded by the Service and will be completed in 1990. At that time the Forest Service may have additional responsibilities with respect to the grizzly bear.

Page I-27, paragraph 5: The 2,200 acre figure for designated spotted owl habitat areas is too low to protect owls in the Forest. Recent studies by the Washington Department of Wildlife indicate that spotted owls in the Washington Cascades require 3,800 acres of old-growth for each owl site (defined as containing an owl pair or individual owl representing the nucleus of a future owl pair; Harriet Allen and Keitlyn Watson, Washington State Department of Wildlife, personal communication). The Service recommends that designated spotted owl habitat areas on the Forest contain at least 3,800 acres of suitable habitat (old-growth forest that is as contiguous as possible), per spotted owl site until such time that research data indicates otherwise. If 3,800 acres of suitable habitat are not available within 2.1 miles of a spotted owl nest, full protection should be given to suitable habitat beyond the 2.1 mile range as appropriate to meet the biological requirements of the owl.

Page I-27, paragraph 6: The spatial arrangement of designated habitat areas for the spotted owl should be based upon the most recent site-specific ecosystem information (e.g. habitat quality with respect to food and competitor species) to improve the probability of survival for the owl. Provision should be made for replacing designated suitable habitat areas that might be destroyed by fire, disease or storm events. All of this will require intensive research and monitoring efforts and close coordination with the Service, Washington Department of Wildlife, and adjacent landowners to the Forest such as the Park Service.

SUMMARY COMMENTS

The Service agrees with the Forest Service that Alternative NC would not meet the requirements of the National Forest Management Act with respect to fish and wildlife resources. If Alternative NC is applied on-the-ground it would cause great loss to

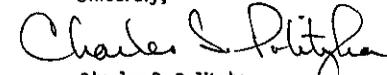

K-391

24468

important fish and wildlife species and their habitat. Consequently, net public benefits for the Forest would be reduced accordingly. The Service recommends that Alternative NC not be adopted.

Management measures for conserving some vertebrate species (presented in the section on "Analysis of Management Requirements") appear to be inadequate. In particular, management measures for protecting the spotted owl need to be strengthened.

Sincerely,

Charles S. Polityka
Regional Environmental Officer

Dear Mr. O'Neal

SUBJECT: REVIEW OF SUPPLEMENT TO THE DRAFT ENVIRONMENTAL IMPACT STATEMENT
(DEIS)/PROPOSED LAND AND RESOURCE MANAGEMENT PLAN FOR THE WENATCHEE
NATIONAL FOREST, WASHINGTON

K-393

Designating a river segment as part of the Wild and Scenic River System can have adverse effects on the availability of public lands for mineral exploration and development. A detailed minerals evaluation has not been completed but is necessary to determine the mineral potential of these river corridors prior to a management decision. The areas having mineral potential should be omitted from the proposed *Scenic and Recreational Classification* System. As noted by the Wenatchee Forest, in a letter dated September 22 1986, Mineral resources are of utmost importance, and they must be properly provided for under a multiple resource management practice.

If we can be of technical assistance in developing mineral data please contact our office. Thank you for the opportunity to review this supplement.

Sincerely,

D'Arcy J. Banister, Supervisor

COMMENTS ON SUPPLEMENT TO THE DRAFT EIS WENATCHEE NATIONAL FOREST

The Bonneville Power Administration has reviewed subject document and offer the following comments

As stated in our comments on the Draft EIS in September 1987 we would again like to comment that, in the Northwest, the only National Forest areas we are aware of that are known as exclusion areas are those designated as Wilderness Areas, Primitive Areas, or National Recreation Areas (where specifically excluded by legislation). Therefore, to be consistent with Forest Service policy, we believe Research Natural Areas should be identified in the EIS as avoidance areas rather than exclusion areas. Bonneville Power Administration would make every effort to avoid Research Natural Areas.

K-394

1. The No Change Alternative analyzed in the Supplement to the Draft EIS should not be selected since it does not provide for the mitigation and enhancement of fish habitat, as do some other alternatives, and may not achieve compliance with regulations
2. We suggest that the Final EIS identify any protected areas, as determined by the Northwest Power Planning Council and BPA, within or affected by activities in the Wenatchee National Forest
3. We suggest that the following sources of information may be useful in your planning process

-The Pacific Northwest Hydropower Data Base and Analysis System.
This data base contains detailed, site-specific information over 2,000 individual hydro project applications submitted to the Federal Energy Regulatory Commission. Data include physical location, institutional status, hydrologic characteristics, cost, and planned power output.

-The Pacific Northwest River Study. The Rivers Study resulted in the Northwest Environmental Data Base, containing an inventory and assessment of the region's rivers for their resident fish, wildlife, natural and cultural features, and recreation values, as well as existing institutional constraints. The data base also contains information on anadromous fish collected by the Northwest Power Planning Council.

-BPA is working with the U.S. Geological Survey to automate 1 100,000 scale digital hydrography for the entire Pacific Northwest. The Wenatchee National Forest covers parts of Hydrologic Cataloging Units 17020009, 17020011, and 17030001. All unit except 17020010 are complete and available. The remaining unit should be complete within 6 months

For additional information on these sources, please contact Mr. Tom Pansky, (503) 230-3969, or FTS 429-3969. He would also appreciate any additional information you may secure or generate during your planning processes for inclusion in the above data bases. Also, if you discover any errors in these data bases, please inform him so that they can be corrected. Both tabular and graphic data (for our Geographic Information System) would be appreciated, particularly if it could be tied to EPA River Reach code.

Sincerely,

for Nicholas J. Stas

re: Draft EIS - Wenatchee National Forest
Proposed Land and Resource Mgt Plan
River Classifications

Dear Sonny:

For the most part I would like to go on record supporting your preferred Alternative C as presented in the Supplemental Draft EIS. I do have, however, some strong reservations regarding the selection process and the final lists of ineligible and eligible streams.

Specifically, while most of the streams judged to be ineligible (Table S-4) are now heavily roaded and their watersheds committed to relatively intense silvicultural activities, there are three streams on that list which I believe are eligible for inclusion in the wild/scenic rivers list. Not only are they eligible by definition, but I would place them even higher on the list of priorities than several streams presently listed. The three streams are the Waptus River on the Cle Elum District and the Mad and North Fork Entiat Rivers on the Entiat District. The very justifications used to include the Entiat River (page S-35) can be applied to each of these three streams.

I find it hard to believe that the combined professional judgment of your evaluation team(s) concluded that these streams have "No outstandingly remarkable value". The simple fact that they are basically unroaded basins is remarkable in itself. The scenic values of each basin are outstanding, particularly going into the Waptus River drainage. Fishery values are at least above average in each stream, and for resident, wild trout, the Mad River is outstanding. I must conclude that there were other, overriding considerations utilized in the selection process which had nothing to do with the actual eligibility criteria. Is it possible that concerns for future silvicultural activities, or for present (and future) use of motorized travel precluded these streams from actually being considered on an even par with the rest of the "potential streams" list?

#1488

1488

Sonny J. O'Neal
Page 2

I suggest that a review of the eligibility determination process is necessary. I strongly urge you to reconsider the above three streams for inclusion, with the very same justifications used for the Entiat River, including the addition of "above average fishery values" for the Waptus River and North Fork Entiat. The Waptus River, in particular, deserves as much consideration as any of the other inclusions for Wild River status where the major portions lie within an existing Wilderness Area.

Sincerely,

Wenatchee, Wa 98801

Gentlemen.

In response to your reconsideration and potential designation of eight rivers in Chelan County as "wild & scenic", we oppose these Federal designations. Chelan County, along with the State of Washington, has multitudes of regulations that serve to protect our rivers, lakes, waterways and other environmental areas. We believe that the needs of our County are best met at the local level.

K-396

Your management of Forest Service lands in our County has been outstanding. We encourage you to continue to manage your lands and water resources inside your bounds as you always have. However, we ask you to eliminate any rivers or sections of rivers in our County, which may contain or impact private property, from your proposed wild & scenic designation. Further we would ask you to eliminate any rivers or sections of rivers which such designation may now or in the future impact water rights to any of our agricultural lands.

As we agreed, after you have had time to review the comments and County and State Shoreline regulations concerning this matter, we look forward to discussing your conclusions and the direction you plan to take.

Thank you for your attention to this matter.

Sincerely,
BOARD OF CHELAN COUNTY COMMISSIONERS

Mr. Sonny O'Neal
Forest Supervisor
Wenatchee National Forest
P.O. Box 811
Wenatchee, WA 98801

Dear Mr. O'Neal:

Thank you for your very interesting and informative presentation Monday, January 23, on the wild, scenic and recreational river classification recommendation from the Forest Service. We understand the recommendation and the rationale behind your recommendation to congress on the various rivers mentioned above, and support the concept of good management.

K-397

Due to the tight constraints caused by a January 26 response deadline, we would generally offer the following comments concerning your recommendation to congress on river classification and withhold the right to comment further at a later date concerning the Cle Elum River classification recommendation:

1. We support and encourage local control,
2. We want to be involved in the decision making process in all future river classification actions,
3. We support coalitions that are multiple use advocates and believe that the controlling body for local rivers should be local residents,
4. We oppose restrictions that do not allow for preventative maintenance along streams to prevent erosion of road rights-of-way,
5. We oppose regulations in addition to county ordinances that tend to threaten the livelihood of current or new owners, and
6. We feel that existing ordinances (in Kittitas County) protect the future generations and their right to enjoy the many beautiful rivers in Washington State.

11698

January 20, 1989

Mr Sonny O'Neal, Supervisor
Wenatchee National Forest
PO Box 811
Wenatchee, WA 98807

Dear Mr. O'Neal:

Thank you for this opportunity to provide comments on the supplement to the draft EIS for the proposed Wenatchee National Forest Land and Resource Management Plan (SEIS). Unlike several other supplements to draft plans in Region 6, the Wenatchee National Forest's (WNF) SEIS recognizes that Indian treaty rights must be complied with in all alternatives and play an important role in guiding forest management. See SEIS at II-72. This recognition, along with the WNF's relatively more detailed treatment of water quality management bodes well for future dealings between the Columbia River treaty tribes and the Forest.

Although the WNF obviously took greater care than several other forests in the preparation of its analysis of water quality and riparian area management, inconsistencies and gaps remain. For example, the SEIS states that the no change (NC) alternative fully complies with all state water quality standards. SEIS at II-10. However, this appears to be contradicted by the WNF's declaration that fish habitat and population would be decreased over time, *Id.* at II-24, and that the NC alternative may not maintain viable populations of vertebrate species. *Id.* at IV-8. Moreover, it appears that the WNF thinks it is quite possible to cause very extensive impacts on smaller drainages and still comply with state water quality standards. See *Id.* at IV-12. Given these interpretations, promises that future management activities will comply with state water quality standards do little to ease our concern.

Another area that needs clarification is the WNF's assertion that commercial harvest of WNF anadromous fish will increase almost eight-fold over the next 50 years, *Id.* at II-41, yet habitat will only increase by approximately 2%. *Id.* at II-42. If existing habitat capacity for chinook is six-times existing populations, *Id.*, how is it possible to increase these populations eight-fold?

To: Mr. Sonny O'Neal

01/20/89

In its discussion of its minimum management requirements (MMRs), the WNF sensibly notes that "[t]he management requirements from NFMA and its implementing regulations are legal requirements. They represent 'ends' which must be met during forest plan implementation." SEIS at Appendix I-2. Unfortunately, the WNF does not address this issue in this discussion of its water quality and riparian protection MMRs. In addition, the Forest never identifies viable population levels or "ends" for any species of anadromous fish. Given their designation as management indicator species and their treaty-protected status, this lapse is not only unfathomable, it fails to meet the requirements of NFMA regulations. *Id.* at Appendix I-1-2.

Instead of describing the riparian and water quality conditions or "end" to be achieved by the water quality/riparian area MMR, the WNF merely states that the goal is to "protect water quality and riparian habitat." *Id.* at Appendix I-4. As the means to achieve this amorphous "end," the WNF declares that lands within 100 feet of perennial streams must be given "special attention," *Id.*, in order to prevent "unacceptable erosion and sedimentation that would exceed state standard." *Id.* at Appendix I-5. At present, Washington does not have a sediment standard. Regardless, the NFMA requires the Forest Service to prevent "unacceptable erosion and sedimentation." What is "unacceptable?"

It is clear that the WNF has quantified "special attention" and "unacceptable erosion and sedimentation" because it managed to estimate the opportunity costs of two different water quality/riparian habitat protection methods. See *Id.* at Appendix I-35. The WNF's discussion of its two different approaches towards meeting its undefined MMR fails to provide the information that resource professionals need in order to exercise their best professional judgment. For example, in describing the least protective method, which the WNF is tentatively adopting, the Forest states that it would leave trees in the riparian zone that "will provide the necessary woody debris in the streams." *Id.* at Appendix I-34. In addition the Forest states that "[m]anagement position would require an adequate amount of streamside vegetation for shading to be left so that stream temperatures would remain within acceptable limits." *Id.* (emphasis added). These statements may provide reassurance, but they do not inform.

Because of the WNF's failure to identify "ends" for its water quality/riparian habitat MMR, there is no reasonable way to evaluate which of the Forest's two proposed methods best achieve the MMR. Thus, it is unfortunately no surprise that the Forest adopted the method least protective of riparian resources. The

1169 S

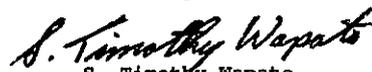

To: Mr. Sonny O'Neal

01/20/89

Forest must revise its discussion of MMRs by specifically identifying its "ends" or objectives and then describing in detail how its proposed methods will achieve those "ends." Second, the Forest must determine the numbers and distribution of individuals that constitute "viable populations" for all anadromous fish species on the WNF.

In developing MMRs for water quality, riparian habitat, and fish population, the WNF must remember that the treaties between the Columbia River treaty tribes and the federal government are binding on the Forest Service. Compliance with the tribes' right to take fish at their usual and accustomed places is no less a requirement on the Forest Service than meeting state water quality standards and complying with the NFMA. The Commission would like to work with the Forest to help remedy these defects.

Sincerely,

S Timothy Wapato
Executive Director

1173b

Confederated Tribes and Bands
of the Yakima Indian Nation

Established by the
Treaty of June 9, 1855

Forest Supervisor
Wenatchee National Forest
PO Box 811
Wenatchee, WA. 98807

January 11, 1989

Dear Mr. O'Neil

The Yakima Indian Nation has reviewed the Supplement to the Draft Environmental Impact Statement for the Wenatchee National Forest Proposed Land and Resource Management Plan. We have the following fisheries related comments:

1. With regard to the No change alternative, aside from the fact that it does not comply with the National Forest Management Act, in that it addresses only a single resource, we are opposed to this alternative in that it fails to protect Treaty reserved fishing rights. The No change alternative fails to provide adequate protection for fisheries and water resources. Because it does not meet Federal Statutes, we do not feel further discussion is warranted.

K-400

2. We appreciate the opportunity of speaking with members of your staff regarding the Wild and Scenic issues developed in the Supplement. It has been our experience that when a water related area receives special designation, particularly with increased recreational opportunities in mind, Tribal fishing and fish protection activities are reduced. A recent example is designation of the Columbia Gorge as part of the Wild and Scenic System. With the advent of the additional windsurfing activities in that area, there have been additional conflicts between the windsurfers and Tribal fisherman. The new designation for the Gorge has made this situation worse, as additional windsurfing sites are proposed that will increase use in these fishing areas. We feel that recreational designation of rivers within the Forest will result in the same outcome, with additional campsites, "vistas", new roads, and loss of riparian vegetation. We therefore are opposed to designating the Chiwawa and Icicle Rivers as Recreational, since they meet the criteria for Scenic. We are also opposed to the Scenic designation for the Entiat River in that portion that meets the Wild designation criteria. We oppose the recreational designation for other rivers proposed for this designation, and support those systems that are proposed for Wild or Scenic designation. We do this if it is understood that we will be involved with any watershed management planning that develops from these designations. These management plans must be consistent with protecting fisheries resources first and foremost. Additional recreational use can not have priority over Treaty protected resources.

3. As you are aware, the Yakima Indian Nation and the Columbia River Intertribal Fish Commission have been working with the Regional Office in defining desired future conditions and

Post Office Box 151 Fort Road Toppenish WA 98948 (509) 865 5121

standards for Region 6 Forests in the Columbia Basin. Our position is that these desired future conditions and standards should be the Management Requirements of the Forest, necessary to protect fisheries resources. The MMR's outlined in the Supplement do not provide the same level of protection that have been provided to the R.O. by the Yakima Indian Nation and the Fish Commission.

If you have further questions regarding these issues, please contact Carroll Palmer, Deputy Director of Natural Resources at 509-865-5121. Thank you very much.

Sincerely,

Don Tahkeal
Don Tahkeal, Secretary
Timber Committee
Yakima Indian Nation

Multiple use management will be the overall goal of the Wenatchee National Forest. The land allocations shown by the management areas on this map are in response to the issues being addressed by this alternative. Many uses will occur in each management area, but one or more resources or uses will be emphasized as shown in the following chart.

EF-1 Experimental Forest Provide opportunities to study the effects of forest management and the on vegetative, soil and water resources.

EW-1 Manage deer and elk in winter range to meet habitat requirements for sustaining maximum carrying capacity.

EW-2 Maintain and enhance riparian management areas to perpetuate their distinctive resource values to maintain fish habitat, water quality, and diverse wildlife habitat. Riparian zones are linear features. However, due to the scale of this map, the zones are shown as blocks at regular intervals.

GF Provide for the greatest long-term growth and production of commercially valuable wood products at a level of investment in timber culture practices that maximizes net public benefits.

OG-1 Manage for old growth habitat to achieve ecosystem diversity, preservation of aesthetic qualities, and/or wildlife and plant habitat.

OG-2 Manage for mature to old growth habitat for wildlife and plant species dependent upon this habitat.

RE-1 Provide developed recreation such as campgrounds, ski areas, and picnic areas.

RE-2A Provide dispersed, unroaded recreation in a semi-primitive motorized recreation opportunity setting. Use could include motorized equipment such as trailbikes and snowmobiles.

RE-2B Provide dispersed, unroaded recreation in a semi-primitive motorized recreation setting. Use could include motorized equipment such as 4-wheel-drive vehicles, trailbikes, and snowmobiles.

RE-3 Provide dispersed recreation in an unroaded, semi-primitive setting where motorized vehicles are not permitted.

RM-1 Provide for maximum forage production and utilization by commercial livestock with a high level of investment in range cultural practices.

RM-2 Provide for research in ecosystems influenced only by natural processes.

RM-3 Manage Special Areas for recreation use, substantially in their natural condition.

SI-1 Manage areas of significant cultural, geological, botanical, zoological, paleontological, or other special characteristics as to protect, preserve, and enhance their intrinsic values.

SI-2 To retain or enhance the viewing and recreation experiences along scenic travel routes.

ST-1 Provide a natural appearing foreground and middleground along scenic travel corridors.

UC-1 Provide and manage utility corridors to accommodate energy transmission needs. This prescription is distributed among other allocations and is not shown on the map.

WI-1 Provides protection of classified wilderness areas in accordance with the Wilderness Act of 1964.

WS-1 Preserve the Scenic River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

WS-2 Preserve the Recreational River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

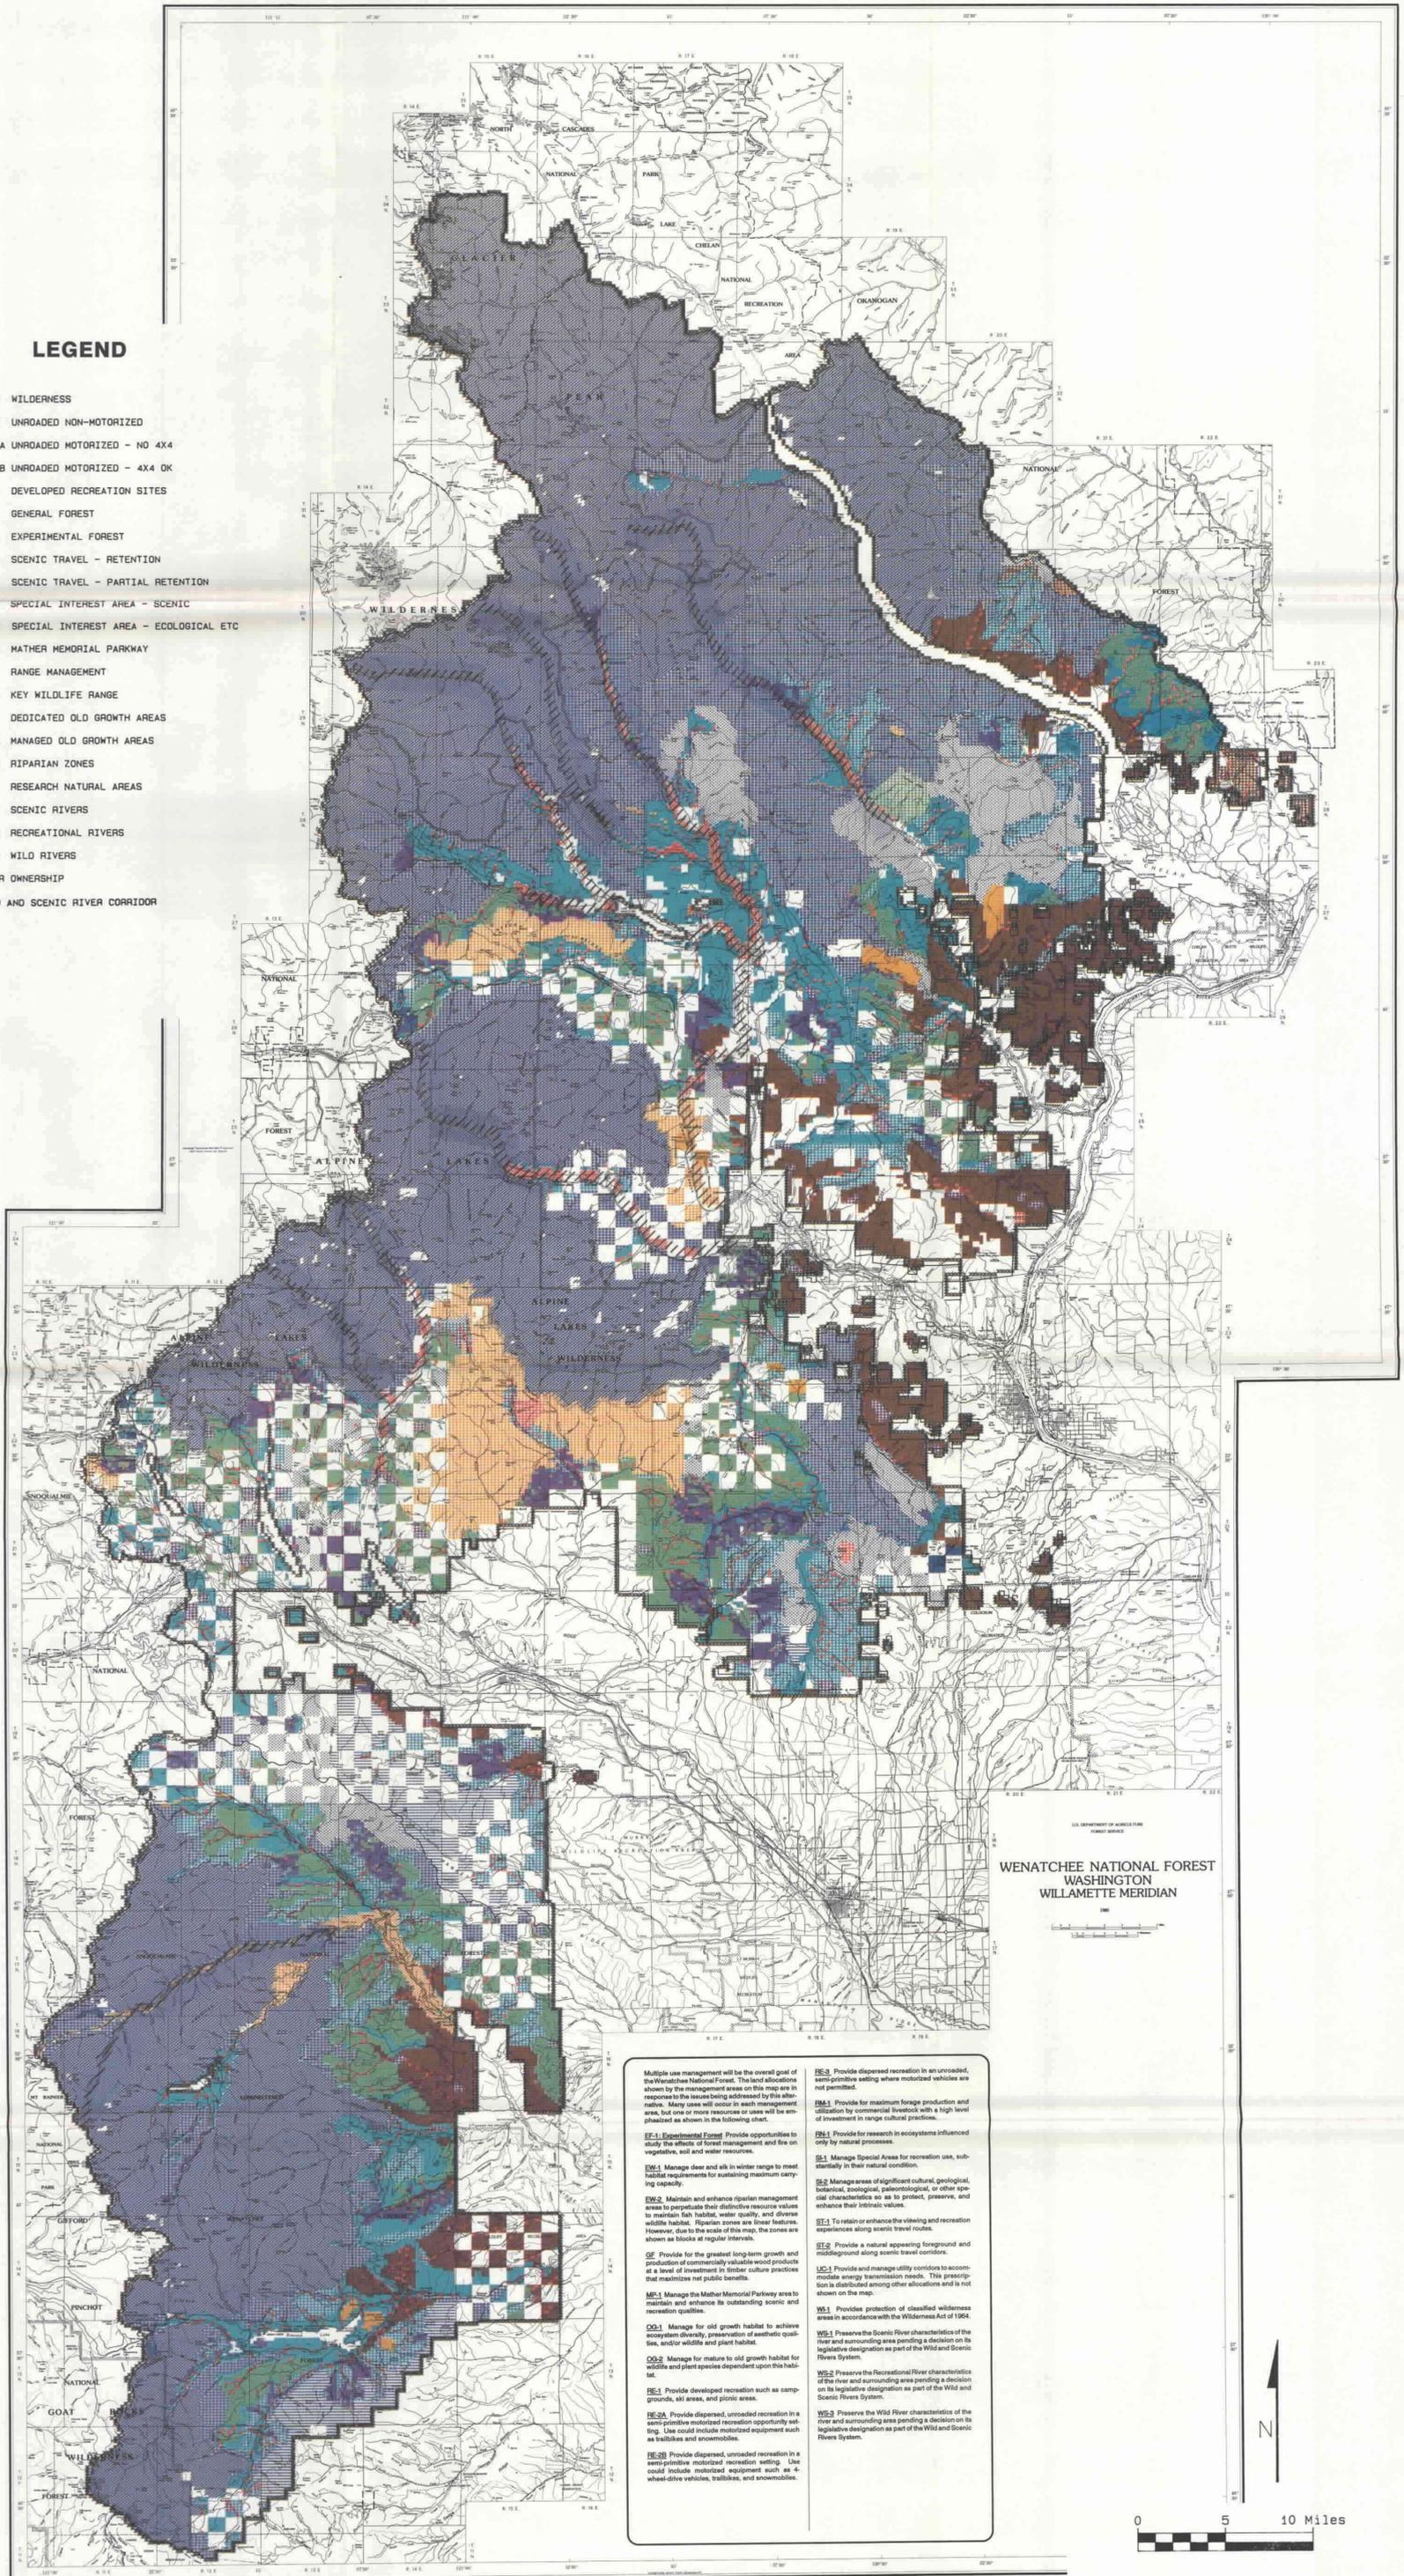

WS-3 Preserve the Wild River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

Multiple use management will be the overall goal of the Wenatchee National Forest. The land allocations shown by the management areas on this map are in response to the issues being addressed by this alternative. Many uses will occur in each management area, but one or more resources or uses will be emphasized as shown in the following chart.

EF-1 Experimental Forest Provide opportunities to study the effects of forest management and fire on vegetative, soil and water resources.

EW-1 Manage deer and elk in winter range to meet habitat requirements for sustaining maximum carrying capacity.

EW-2 Maintain and enhance riparian management areas to perpetuate their distinctive resource values to maintain fish habitat, water quality, and diverse wildlife habitat. Riparian zones are linear features. However, due to the scale of this map, the zones are shown as blocks at regular intervals.

GF Provide for the greatest long-term growth and production of commercially valuable wood products at a level of investment in timber culture practices that maximizes net public benefits.

MP-1 Manage the Mather Memorial Parkway area to maintain and enhance its outstanding scenic and recreation qualities.

OG-1 Manage for old growth habitat to achieve ecosystem diversity, preservation of aesthetic qualities, and/or wildlife and plant habitat.

OG-2 Manage for mature to old growth habitat for wildlife and plant species dependent upon the habitat.

RE-1 Provide developed recreation such as campgrounds, all areas, and picnic areas.

RE-2A Provide dispersed, unroaded recreation in a semi-primitive motorized recreation opportunity setting. Use could include motorized equipment such as trailers and snowmobiles.

RE-2B Provide dispersed, unroaded recreation in a semi-primitive motorized recreation setting. Use could include motorized equipment such as 4-wheeled vehicles, trailers, and snowmobiles.

RE-3 Provide dispersed recreation in an unroaded, semi-primitive setting where motorized vehicles are not permitted.

RM-1 Provide for maximum forage production and utilization by commercial livestock with a high level of investment in range cultural practices.

SI-1 Provide for research in ecosystems influenced only by natural processes.

SI-2 Manage Special Areas for recreation use, substantially in their natural condition.

SI-3 Manage areas of significant cultural, geological, botanical, zoological, paleontological, or other special characteristics so as to protect, preserve, and enhance their intrinsic values.

ST-1 To retain or enhance the viewing and recreation experiences along scenic travel routes.

ST-2 Provide a natural appearing foreground and midground along scenic travel corridors.

UC-1 Provide and manage utility corridors to accommodate energy transmission needs. This prescription is distributed among other allocations and is not shown on the map.

WE-1 Provides protection of classified wilderness areas in accordance with the Wilderness Act of 1964.

WS-1 Preserve the Scenic River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

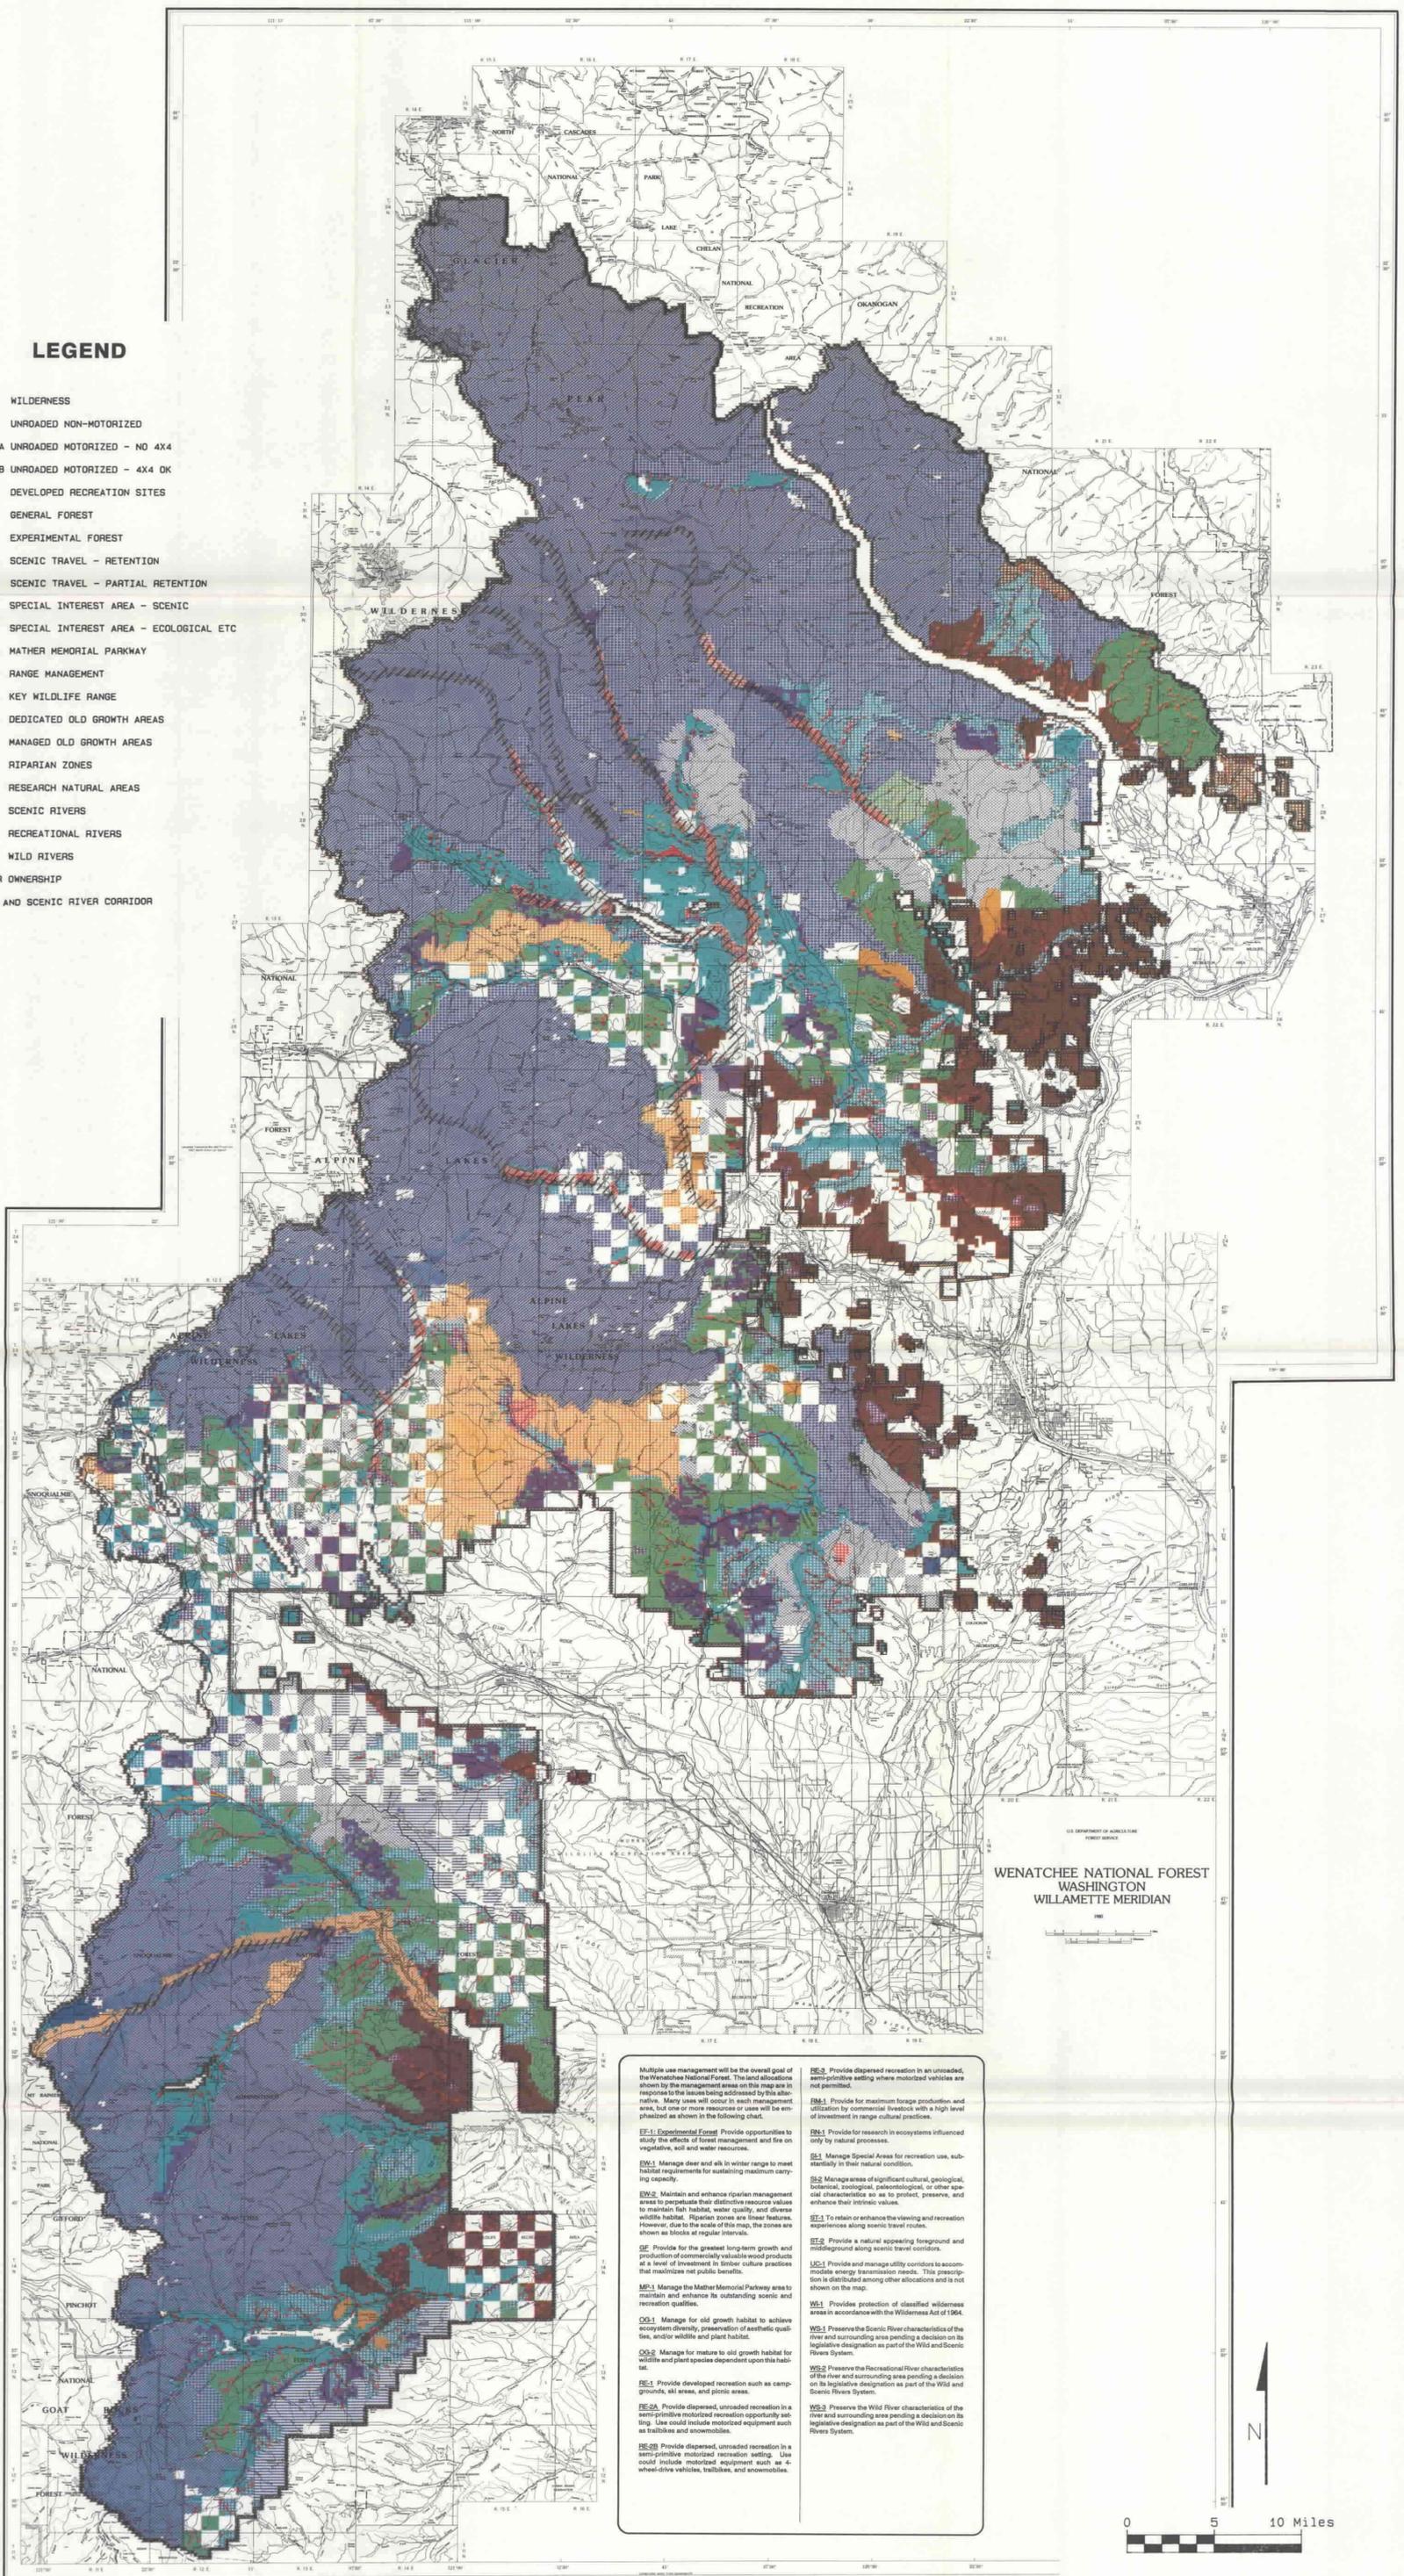

WS-2 Preserve the Recreational River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

WS-3 Preserve the Wild River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

Land and Resource Management Plan

Wenatchee National Forest

PREFACE

This National Forest Land and Resource Management Plan is developed to direct the management of the Wenatchee National Forest. The goal of the Forest Plan is to provide a management program reflective of a mixture of management activities that allow use and protection of the Forest resources; fulfill legislative requirements; and address local, regional and national issues and concerns.

The Forest Plan will be reviewed (and updated if necessary) at least every 5 years. It will ordinarily be revised on a 10-year cycle, or at least every 15 years.

This Land and Resource Management Plan has been prepared according to Secretary of Agriculture regulations (36 CFR 219) which are based on the Forest and Rangeland Renewable Resource Planning Act (RPA) as amended by the National Forest Management Act of 1976 (NFMA).

The Plan has also been developed in accordance with regulations (40 CFR 1500) for implementing the National Environmental Policy Act of 1969 (NEPA). The Forest Plan represents the implementation of the preferred alternative as identified in the Final Environmental Impact Statement (FEIS) for the Wenatchee National Forest.

Additional direction used in developing this Forest Plan came from the Final Environmental Impact Statement for the Pacific Northwest Regional Guide, 1984, as amended December 8, 1988.

If any particular provision of this Forest Plan or its application to any person or circumstances, is held invalid, the remainder of the Forest Plan and its application of that provision to other persons or circumstances shall not be affected.

Further information pertaining to this plan can be provided by:

CHAPTER I

FOREST PLAN INTRODUCTION

A. PURPOSE OF THE FOREST PLAN

The Forest Plan guides all natural resource management activities and establishes management standards and guidelines for the Wenatchee National Forest. It describes resource management practices, levels of resource production and management, and the availability and suitability of lands for resource management.

The decisions of the Regional Forester in approving a Forest Plan may generally be categorized as:

1. Establishment of forest-wide multiple-use goals and objectives [36 CFR 219.11(b).];
2. Establishment of forest-wide standards and guidelines to fulfill requirements of NFMA applying to future activities [resource integration requirements of 36 CFR 219.13 to 219.26, and the requirements of 36 CFR 219.27];
3. Establishment of management area direction including management area prescriptions and standards and guidelines applying to future management activities in that management area [36 CFR 219.11(c).];

4. Establishment of allowable timber sale quantity and designation of suitable timber land [36 CFR 219.16 and 219.14]; and

5. Establishment of monitoring and evaluation requirements [36 CFR 219.11(d)].

The Forest Plan embodies the provisions of the National Forest Management Act of 1976, its implementing regulations, and other guiding documents. Land use determinations, prescriptions, and standards and guidelines are a statement of the Plan's management direction; however, the project outputs, services, and rates of implementation are dependent on the annual budgeting process.

This Forest Plan establishes the management direction for the Wenatchee National Forest and it will ordinarily be revised on a 10 year cycle, or at least every 15 years.

B. RELATIONSHIP OF THE FOREST PLAN TO OTHER DOCUMENTS

This Forest Plan sets forth the direction for managing the land and resources of the Wenatchee National Forest. The Plan results from extensive analysis and considerations that are addressed in the accompanying Environmental Impact Statement (EIS) and Record of Decision. The planning process and the analysis procedures that were used to develop this Plan are described or referenced in the EIS. The EIS also describes other alternatives considered in the planning process.

Specific activities and projects will be planned and implemented to carry out the direction in this Plan. The Forest will perform environmental analysis on these projects and activities. Project level environmental analysis will use the data and evaluations in the Plan and EIS as its basis. Environmental analysis of projects will be tiered to the Environmental Impact Statement (EIS) accompanying this Forest Plan.

REGIONAL GUIDE

The Regional Guide for the Pacific Northwest Region (June 1984) as amended December 8, 1988 provides direction for National Forest Plans. It includes standards and guidelines addressing major issues and management concerns considered at the Regional Level, to facilitate Forest planning.

ALPINE LAKES MANAGEMENT PLAN

The Alpine Lakes Area Management Act of 1976 (PL 94-357) required that a separate plan be developed for the Alpine Lakes Area. This plan and Environmental Impact Statement was developed with extensive public involvement, and implemented early in 1982. The regulations guiding the development of Forest Plans state that "if, in a particular case, special area authorities require the preparation of a separate special plan, the direction in any such plan may be incorporated without modification in plans prepared under (these regulations)," (36 CFR 219.2(b)).

The area has been managed under the above plan for approximately eight years. To date, neither the Forest Service nor the public have identified any major problems with the allocation or management of that plan. Some minor adjustments have been made in Management Requirements for water, wildlife and fish to meet NFMA standards. Preliminary administrative recommendations will be made for some rivers for consideration under the Wild and Scenic Rivers Act. In good faith to those members of the public who helped develop that plan, the Forest Plan incorporates the land allocations and management as presented in the Alpine Lakes Area Land Management Plan. Both the Wenatchee and the Mt. Baker-Snoqualmie Forests are in agreement with this direction which will allow that plan to stand the test of time. Problems which surface could be handled administratively or when the Forest Plan is revised in approximately ten years.

If direction in this Plan is found not to agree with the direction contained in the Alpine Lakes Management Plan, the Alpine Lakes Plan will take precedence for the Alpine Lakes Management Unit with the exception of some management requirements for water, wildlife and fish and protecting of eligible Wild and Scenic rivers. Copies of the Alpine Lakes Plan are available for review at the Wenatchee National Forest Supervisor's Office, 301 Yakima Street, Wenatchee, Washington.

PROJECT PLANNING

The Forest Plan serves as the single land and resource management plan for the Wenatchee National Forest. All other land management plans are replaced by the direction in this Forest Plan; see Chapter V for a listing of existing plans that this Forest Plan supersedes.

The management direction provided by this Forest Plan comprises the framework within which project planning and activities take place.

C. PLAN STRUCTURE

The Forest Plan is organized into five chapters and seven supplemental sections. They are:

Chapter I - Forest Plan Introduction describes the purpose of the Plan, summarizes its content, illustrates the geographic location, and discusses the Plan's relationship to other documents.

Chapter II - Provides a Summary of the Analysis of the Current Management Situation (AMS). Included are summaries of the current management situation for each resource, potential supply for various resource goods and services, a brief look at demand, and a brief socioeconomic overview of the Forest and related communities and counties.

Chapter III - Contains the Responses to Issues, Concerns, and Opportunities. This chapter shows how the management plan addresses and responds to the major public issues, and management concerns identified during the planning process.

Chapter IV - Forest Management Direction. This chapter is the heart of the Plan and presents the management goals, objectives, and standards and guidelines that constitute direction for resource management covered by the plan.

Chapter V - Implementation Of The Forest Plan - This chapter explains how management direction will be implemented, how implementation activities will be monitored and evaluated, and how the plan can be kept current in light of changing conditions or other findings.

Glossary - This section contains Forest Plan terms that need a common understanding or which have special meanings.

Appendix A - Included are detailed schedules of projected activities by resource.

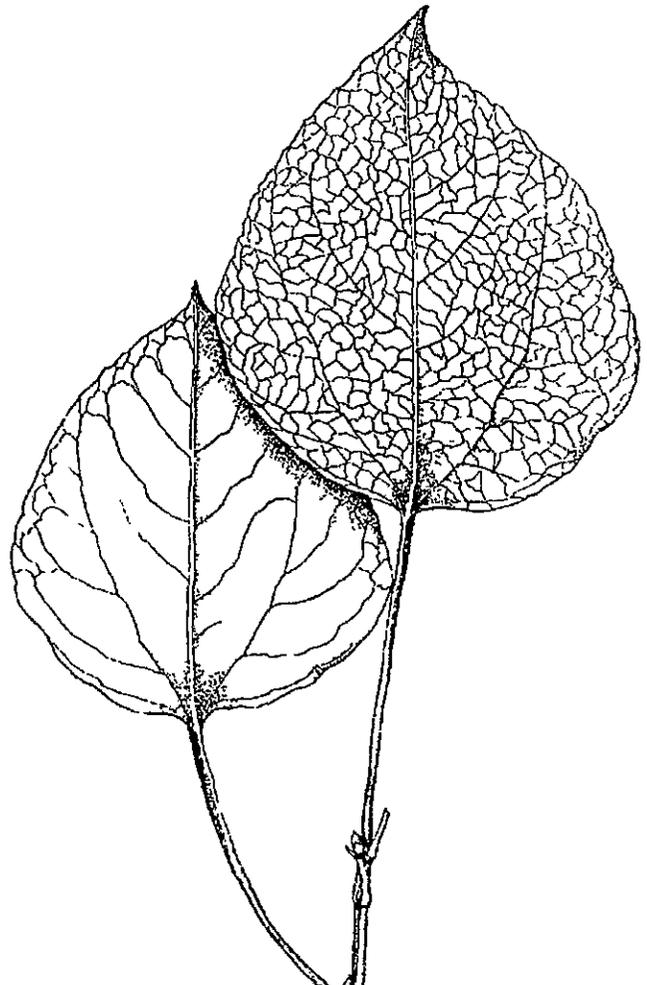

Appendix B - Includes the land classification ownership direction by management prescription

Appendix C - Includes a copy of the Treaty With The Yakima, 1855.

Appendix D - Is a Fire Management Policy Model decision matrix.

Appendix E - Is The Wilderness Management Appendix.

Appendix F - Includes a set of Monitoring Worksheets used to develop the details of the monitoring plan which is summarized in Table V-I of Chapter V.

D. FOREST DESCRIPTION

The Wenatchee National Forest is a publicly owned natural area of marvelous beauty, diversity, and productivity. The Forest includes a net area of 2,164,180 acres. It is about 140 miles long and 25 to 55 miles wide, stretching from spectacular Lake Chelan in the north through the rugged Goat Rocks Wilderness in the south. It begins at the very crest of the Cascade Range in Central Washington State and falls sharply to the breaks of the Columbia River. Elevations on the Forest range from 800 feet to more than 9,500 feet, encompassing three major landforms and more than 30 different geologic formations.

This geologic variety and a wide difference in precipitation across the Forest leads in turn to an unusual diversity in vegetation and an associated richness of wildlife species. The vegetation changes with elevation and moisture as the Forest rises from grass, sage, and bitterbrush in the low-lying eastern areas, through open stands of orange-barked ponderosa pine, and into mixed forests of pine, Douglas fir, and larch. Next it rises into subalpine areas with true firs and lodgepole pine, and finally reaches lush alpine meadows fringed with hardy stands of alpine firs, larch, and whitebark pine.

Areas near the Cascade crest receive up to 140 inches of precipitation and as much as 25 feet of snow accumulation each year. Moisture declines markedly to the east, resulting in near-desert conditions with less than 10 inches of precipitation on the eastern fringes of the forest. However, the generous precipitation and snowpack in the high mountain areas supply hundreds of sparkling alpine lakes and dozens of tumbling streams and rivers. These in turn feed half a dozen large lakes and reservoirs that help water thousands of acres of productive farmland in the fertile valleys of central Washington.

The diversity of the Forest also has led to a great variety of wildlife species. An estimated 394 species of fish and wildlife reside within the forest. These vary from stately elk to the tiny mouse-like pika, from soaring bald eagles to hummingbirds, from leaping salmon to shadowy suckers methodically vacuuming the bottom of lakes and streams.

This wealth of water, wildlife, and scenery plus dependably sunny weather attract millions of recreation-minded visitors to the Wenatchee Forest. Indeed, with nearly 5 million visitor days of use recorded each year, the Forest is one of the half dozen most heavily visited National Forests in the nation. People come to camp, hike, fish, hunt, to take in the scenery, to take pictures, ride horses, drive 4-wheel-drive vehicles and ride motorbikes, to rockhound and pan for gold, to cut firewood, to gather mushrooms, and pick berries. In winter they come to ski (downhill and cross-country), to snowshoe, ride snowmobiles, and play in the snow. This recreation activity is a key ingredient in the tourism industry that has become a cornerstone of the central Washington economy.

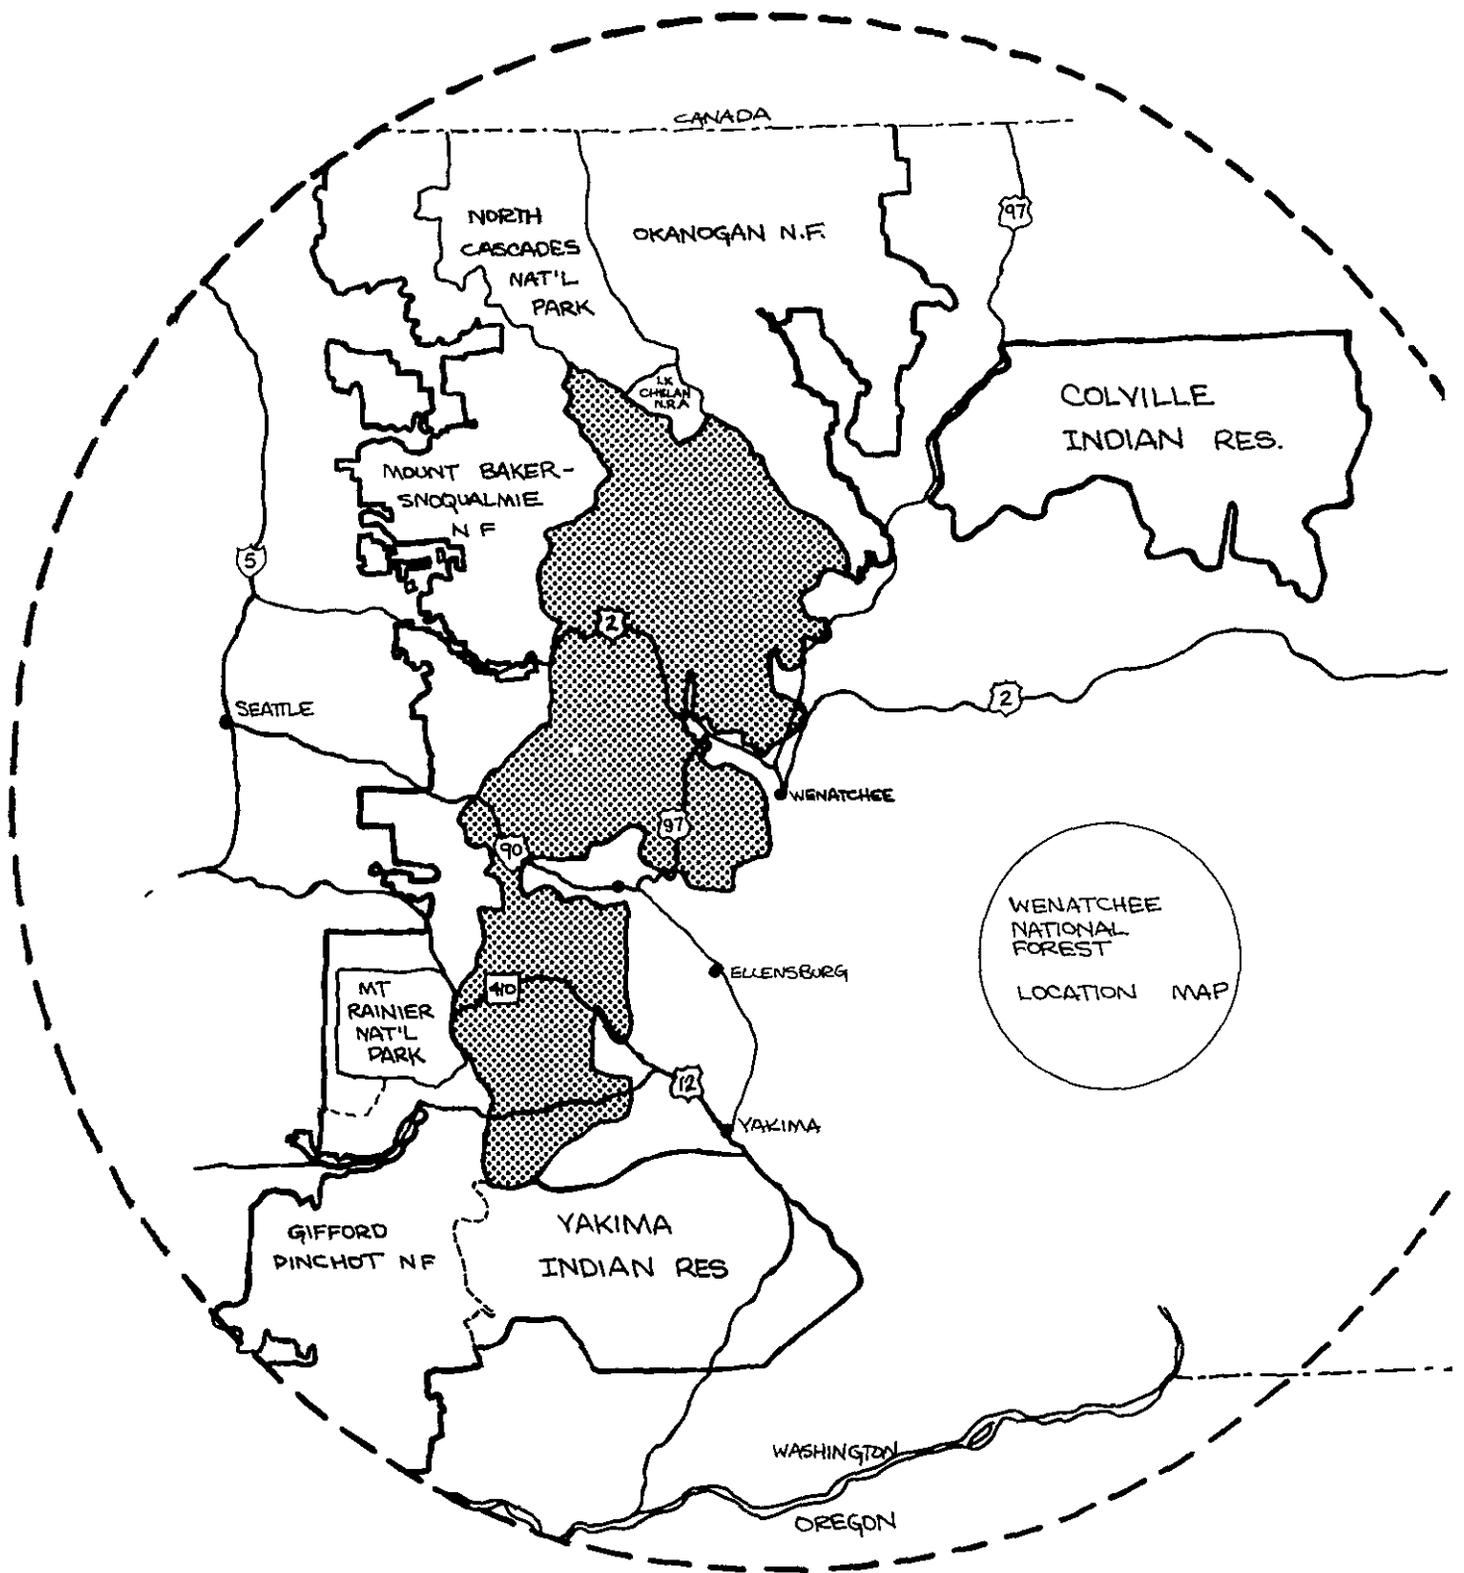

The Wenatchee Forest is also an important producer of sawtimber and other wood products. Trees sold at auction and cut by local companies are mostly processed in Washington State into lumber, plywood, paper, furniture, and firewood. The wood products industry has long been an important employer in many communities within and adjacent to the Forest.

The Forest is also subject to periodic natural disasters like wildfire, floods, windstorms, and insect outbreaks. These occurrences require occasional costly mobilization of people and equipment to minimize damage to forest resources and to rehabilitate impacts which have occurred.

The great diversity of Forest resources and uses translates to complexity in management and Forest planning. The variety of uses also leads to the potential for considerable differences in opinion on which uses should be emphasized in management. These are some of the challenges addressed by this management plan.

WENATCHEE NATIONAL FOREST LOCATION MAP

CHAPTER II

SUMMARY OF THE ANALYSIS OF THE CURRENT MANAGEMENT SITUATION

A. INTRODUCTION

This chapter describes the present condition and current management of the Wenatchee National Forest. It estimates the potential for producing each forest resource, given legal and other requirements. It also describes the supply of market and non-market forest resources and, where possible, the future demand for these resources.

Supply estimates for the current program are based on current management direction for the Forest. The sources of that direction were the Alpine Lakes Management Plan, the Chelan and Kittitas Unit Plans, and Ranger District multiple-use plans. Outputs are based on land allocations contained in these plans, and on up-to-date yield calculations being used in the FEIS.

The production potential for each resource is the amount of goods or services (yields) which could be produced while meeting legal and other minimum requirements. The potential for all resources can not be met at the same time. With few exceptions, when the potential for one resource is maximized, production of another resource will be reduced or eliminated entirely. For example, if maximum timber production is reached, then unroaded recreation and visual quality would be significantly reduced.

Issues, concerns, and opportunities identified by the public and Forest managers during the planning process have helped identify needs for changing current management direction. This change is reflected in the preferred management direction in Chapter IV.

B. ENVIRONMENTAL COMPONENTS

The supply and demand conditions of primary resource elements are detailed under each resource section. Table II-31 which follows the resource narratives, summarizes conditions for these resources.

1. RECREATION SETTING

Overview

A tremendous diversity of elevation, vegetation, and precipitation on the Wenatchee National Forest results in an equal variety of recreation uses and opportunities. The Forest has been the sixth most heavily visited National Forest in the United States for the past several years, and the diversity of uses is unsurpassed.

Recreation is heaviest in the summer months, but occurs in all seasons of the year. In the early spring, hikers, horse users, and trailbike enthusiasts flock to low elevation trails. These activities follow the melting snows upward during the summer until fall storms begin to push users back down into the valleys. Scenic highways and forest roads are equally attractive to visitors, and driving for pleasure is one of the most popular public recreation uses of the Forest. There are 126 campgrounds and picnic areas offering visitors a rustic camping experience for a few hours or for several days.

Because of its size, diversity, and accessibility, the Wenatchee National Forest has a remarkable capacity to absorb recreation use any time of the year. Although recreation use is projected to increase steadily in the future, the Forest has so much to offer that crowding and shortages are expected to be only localized problems.

a. Developed Recreation

1) Current Management Program

The Forest provides a full spectrum of developed recreation opportunities. Table II-1 indicates the kind and number of developed sites now in existence.

**TABLE II-1
KINDS AND NUMBERS OF
RECREATION SITES**

Kind of Site	Number of Each
Observation	3
Boating	7
Trailhead	12
Campground, Family	115
Campground, Organized Group	3
Picnic Ground	8
Hotel, Lodge, or Resort	7
Organization Site	20
Other Recreation Concession	2
Recreation Resident Tract	54
Winter Sports	7
Information	6
TOTAL	244

Most of the use in the developed recreation setting takes place in camp and picnic grounds. These sites were used to near capacity on weekends in 1988.

The resorts, organization sites, and recreation resident tracts which are under special use permits to commercial businesses, organizations, and individuals, provide additional recreation opportunities throughout the Forest.

At the present time, there are 45 campgrounds where a user fee is being charged. This fee ranges from \$3.00 to \$6.00 per day for individual family camp units. There are many multi-family units where the fee is adjusted according to the size of the unit and number of families it will accommodate.

In addition to the family unit campgrounds, the Forest has five group sites that can be reserved in advance at a fee that ranges from \$12.00 to \$50.00.

Seven downhill ski areas offer a variety of skiing opportunities and challenges in alpine, subalpine, and low elevation settings. Stevens Pass, Snoqualmie Pass, and Pac West Ski Areas are administered by the Mt. Baker-Snoqualmie National Forest. White Pass and Mission Ridge are large developments administered by the Wenatchee National Forest that draw skiers from a broad area. Chelan and Leavenworth Ski Areas are modest operations serving local users.

2) Production Potential

The ability of the Forest to produce developed recreation supply is directly related to the potential to expand or develop new facilities. This potential is affected by budgets in addition to the physical capacity for sites. The physical capacity for expanding or developing new sites is not limited for the ten to fifteen years covered by this plan and should not limit the supply through or beyond the 50 year planning horizon.

The Forest Service objective for downhill skiing is to provide the opportunity to the private sector, through special use permits, to develop successful ski areas which enhance the total outdoor recreation spectrum for the general public. There are seven sites on the Forest and current interest is on expansion of the Mission Ridge and White Pass Areas. The Stevens Pass Ski Area has recently expanded by developing an area in the Mill Creek drainage east of Stevens Pass. Additional expansion is expected in that area.

The Chiwaukum Mountains in the vicinity of the Dardanelles on Highway 2 is the most promising potential ski area that has been inventoried. If this potential is pursued, it would be subjected to thorough environmental analysis as required by the National Environmental Policy Act. The analysis would include full public involvement.

3) Demand

The developed recreation sites listed in Table II-1 have a current total capacity of 4,883,000 Recreation Visitor Days (RVD's). Developed recreation use at all sites in 1986 was 2,731,000 RVD's, or 56% of the available capacity. These figures indicate a surplus of 2,152,000 RVD's. However, this surplus is misleading considering the capacity figures include early and late season periods during the use season, and mid-week periods when visitor use is much lower. During most weekends and holidays during the use season, sites are filled to capacity. When sites are operating at full capacity, users crowd into areas, resulting in problems such as strained sanitation systems and water supplies, and conflicts between users and impacts on vegetative and soil resources. Expansion and improvements at many of the sites is planned for the first decade, increasing the capacity of sites to 6,683,000 RVD's. This figure includes proposed expansion of ski areas and other private sector development on the Forest. This capacity is expected to be adequate through the life of this Plan.

Estimated recreation demand through the fifth decade planning period was obtained from the 1979 Washington State-wide Comprehensive Outdoor Recreation Plan (SCORP). This plan estimates that demand for developed recreation activities would increase about 20%, 12%, 7%, 10% and 7% per-year through the five decade planning period. To reach demand estimates, visitor use figures for 1986 were projected by the estimated increase use percentages through the five decade planning period.

b. Dispersed Recreation

1) Current Management Program

Dispersed recreation refers to those recreation activities that occur outside of developed sites such as camp or picnic grounds, resorts, organization sites, etc. It includes such activities as camping in undeveloped areas, hiking, off-road vehicle use (ORV), fishing, hunting, horseback riding, mountain climbing, cross-country skiing, gathering firewood, gathering berries, boating, driving for pleasure, etc.

RECREATION SETTING

There are 2,463 miles of trails on the Forest. Approximately 48 percent of the Forest trails are in wilderness. The Forest Service is currently working with users to develop 4-wheel drive routes, trail bike, cross-country ski, and snowmobile routes. Use of trails by all types of users is steadily increasing. The planning and management of this trail system requires active participation by user groups, a requirement not difficult to achieve in view of the high interest shown. Dispersed recreation outside of wilderness takes place in both a roaded or unroaded setting. Most of the above activities can be enjoyed in either setting, however, some users prefer either one setting or the other for their recreation pursuits. Often recreationists will use both settings during a single visit.

The current management program allocations would retain 261,059 acres outside of wilderness in an unroaded setting. These allocations include:

- a. 64,597 acres in the RE-2 allocation dedicated to unroaded non-motorized recreation.
- b. 59,551 acres in the RE-3 allocation dedicated to unroaded motorized recreation.
- c. 136,911 acres in the SI-1 allocation dedicated to dispersed recreation in a natural unroaded condition.

There were 746,300 RVD's use on these unroaded acres in 1986, or 33% of the total dispersed non-wilderness use.

Roaded dispersed recreation would be available on 1,062,087 acres under current management allocations, however, in 1985 there were 712,900 acres actually in a roaded setting with the remaining 326,842 acres scheduled for development in current land use plans. In 1986 there were 1,514,700 RVD's used on the 712,900 roaded acres or 67 percent of the total dispersed non-wilderness use.

2) Production Potential

The potential of the Forest to provide various settings for non-wilderness dispersed recreation is dependent on the acreage in the roaded and unroaded settings at a given time. The existing setting would provide the maximum unroaded potential and was used as the maximum unroaded benchmark. It would provide 1,365,000 unroaded RVD's capacity. All of this capacity could be dedicated to either unroaded motorized or unroaded non-motorized use. This setting would also produce 17,835,000 RVD's of roaded recreation on the 712,900 roaded acres.

The maximum timber benchmark would approximate the maximum roaded recreation setting. At the end of the 15th decade there would be approximately 1,069,800 roaded acres which would provide 26,746,000 RVD's capacity. This setting would produce 744,000 RVD's capacity on approximately 271,400 unroaded acres, or one-half of the current unroaded capacity.

3) Demand

Table II-2 indicates the estimated projected demand for Dispersed Recreation in terms of Roaded, Unroaded-motorized, and Unroaded-non-motorized uses.

The supply, however, will vary over time as the inventory shifts from an unroaded condition to a roaded condition. The Forest's current supply for each of these categories exceeds the projected demand through the year 2030.

Projected recreation demand was calculated in the same manner as demand for developed recreation, using the 1979 Washington State-wide Comprehensive Outdoor Recreation Plan estimates.

TABLE II-2
DISPERSED RECREATION
Projected Demand
In Millions of Recreation Visitor Days

	DECADE 1	DECADE 2	DECADE 5
Roaded Estimated Projected Demand	1.998	2.126	2.630
Unroaded Motorized Estimated Projected Demand	.279	.301	.405
Unroaded Nonmotorized Estimated Projected Demand	.099	.106	143

The preceding supply and demand figures are based on mathematical formulas and take into account length of stay, season of use, and the concentration of use per-acre for the various ROS settings. Some supply and demand relationships are hard to quantify. Large unroaded areas have a very low visitor use capacity. The assumption is that some users prefer this low density of people and will seek out these opportunities.

There are very few lakes in unroaded areas with motorized trail access. There is an expressed desire by trail bike users for this type of opportunity.

There is a demand for moderate to easy backpacking opportunities for large groups and organizations, in highly scenic, primitive settings. Most of the high quality opportunities are in wilderness, where large party sizes are not permitted.

There appears to be a shortage of similar opportunities for outfitter-guides to take large groups of clients into high quality semi-primitive areas without going into wilderness.

2. WILD, SCENIC, AND RECREATIONAL RIVERS

a. Current Management Program

On October 7, 1968, Congress enacted the Wild and Scenic Rivers Act PL 90-542 which placed eight rivers in the nation under a National Wild and Scenic Rivers System.

As part of the Forest planning process, direction has been given to look at each river on the Nation-wide River Inventory and those not on the inventory, but having public interest expressed in them, to verify that they meet eligibility criteria for inclusion in the National Wild and Scenic Rivers System. This is based upon criteria set forth under sections 1(b) and 2(b) of the Wild and Scenic Rivers Act and as supplemented by USDA-USDI Guidelines.

On the Forest, portions of the Chiwawa, White, and Wenatchee Rivers are included on the current Nationwide River Inventory. Present management of land adjacent to these rivers is guided by Regional direction based on Presidential direction. This states that agencies having rivers listed on the inventory shall take prompt action to protect the rivers and avoid or mitigate adverse effects activities might have on such rivers. Assessment of these rivers is the responsibility of the agency or the State having the largest portion of the river.

As a result of both in-service review and the analysis of comments received from the public during the comment period for the DEIS, the Forest Supervisor formed an interdisciplinary (ID) team to make a reassessment of eligibility for all rivers on the Wenatchee National Forest. The ID Team was also assigned the task of completing a suitability analysis for the resulting eligible rivers.

The ID Team did not conduct an evaluation on the Yakima River, due to the non-Federal ownership of most lands adjacent to the river. The 1.25 miles within the National Forest boundary is not considered eligible because it does not have an outstandingly remarkable feature. National Forest lands make up less than one percent of the ownership of the 102 mile river length. The State of Washington may conduct a study of the Yakima River under the Washington State Scenic Rivers Program.

b. Production Potential

Of the 33 rivers analyzed, 10 were found by the ID Team to be eligible, and were classified as "wild, scenic, or recreational." The following table indicates the highest potential classification for which these river segments qualify.

c. Demand

There has been public support for and against recommendation of the following rivers to Congress for consideration under the Wild and Scenic Rivers Act. Most of the input received against recommendation has come from local residents who live on or near the rivers, and are concerned with excessive government controls and/or acquisition of their property.

TABLE II-3
HIGHEST POTENTIAL RIVER CLASSIFICATION
UNDER THE WILD & SCENIC RIVERS ACT

River	Segment ^{1/}	Classification	Length/Miles		Total
			NF	Other	
AMERICAN	Headwaters to confluence w/Rainier Fork	Wild	6.0	0	6.0
	Confluence w/Rainier Fork to confluence w/ Bumping River	Scenic	16.0	0	16.0
CLE ELUM	Headwaters to Alpine Lakes Wilderness boundary	Wild	4.0	0	4.0
	Alpine Lakes Wilderness boundary to Salmon La Sac Bridge	Scenic	6.0	10.0	16.0
	Salmon La Sac Bridge to head of Lake Cle Elum	Recreational	3.5	1.0	4.5
WAPTUS	Headwaters to confluence with Cle Elum River	Wild	13.0	0	13.0
ICICLE	Headwaters to Alpine Lakes Wilderness boundary	Wild	12.0	0	12.0
	Alpine Lake Wilderness Boundary to 2.5 miles above National Forest boundary	Scenic	7.5	6.5	14.0
	2.5 miles above National Forest boundary to National Forest boundary	Recreational	0.5	2.0	2.5
LITTLE WENATCHEE	Riverside CG Falls to Lake Wenatchee	Scenic	5.5	2.5	8.0
NAPEEQUA	Headwaters to Glacier Peak Wilderness boundary	Wild	15.0	15.0	15.0

	Cottonwood trailhead to private land boundary	Scenic	15.0	0	15.0
WENATCHEE	Lake Wenatchee to National Forest boundary	Recreational	14.75	13.25	28.0

^{1/} Some segments have been combined for this table.

3. CULTURAL RESOURCES

a. Current Management Program

The cultural resource base of the Wenatchee National Forest includes a diverse and unusually rich range of historic and prehistoric artifacts and sites. These include: 1) historic cabins, trails, mines, ditches, railroad grades, emigrant trails, original highway grades, mills, and homesteads; 2) historic Forest Service structures including guard stations, lookout towers, corrals, camps, administrative centers, and Depression-era campgrounds and buildings; and 3) prehistoric campsites, villages, graves, quarries, pictographs, workshops, trails, rock shelters, and religious sites.

In accordance with the National Historic Preservation Act of 1966 as amended, the National Environmental Policy Act of 1969, as well as a series of implementing regulations and policy direction, the Forest has undertaken a program to identify, evaluate, preserve, protect, and interpret the cultural resources. A cultural resource overview, pulling together most of the recorded information relating to the prehistoric and ethnographic uses of the Forest, has been completed, and is available for review at the Forest Supervisor's office. An overview of the historic resources of the Forest still needs to be completed.

Between 1976 and 1985 cultural resources were inventoried on about 123,372 acres of the Forest, or 6 percent of the total Forest acreage. Most field examinations have been done in conjunction with other Forest activities. These surveys have determined the location and nature of cultural sites within potential project areas. At the present rate, project inventory will be completed at a rate of about 30,000 acres per year. Most of this will be in support of the timber sale program.

Inventories have been mostly confined to surface examinations only. Archaeological test excavations have been carried out at five sites on the Forest to determine their subsurface extent and potential eligibility for inclusion in the National Register of Historic Places. These sites were selected for testing because of their relationship to planned timber sales and campground developments. Ultimately the data retrieved may provide important contributions to archaeological research.

Table II-4 is a summary of the known and reported cultural resources of the Forest as of 1985. Historic sites are those associated with the period for which there are written records. In central Washington, the historic era begins at roughly 1805 A.D., with the Lewis and Clark expedition on the lower Columbia River. Prehistoric sites are those predating this period, and are linked to the American Indians and their ancestors.

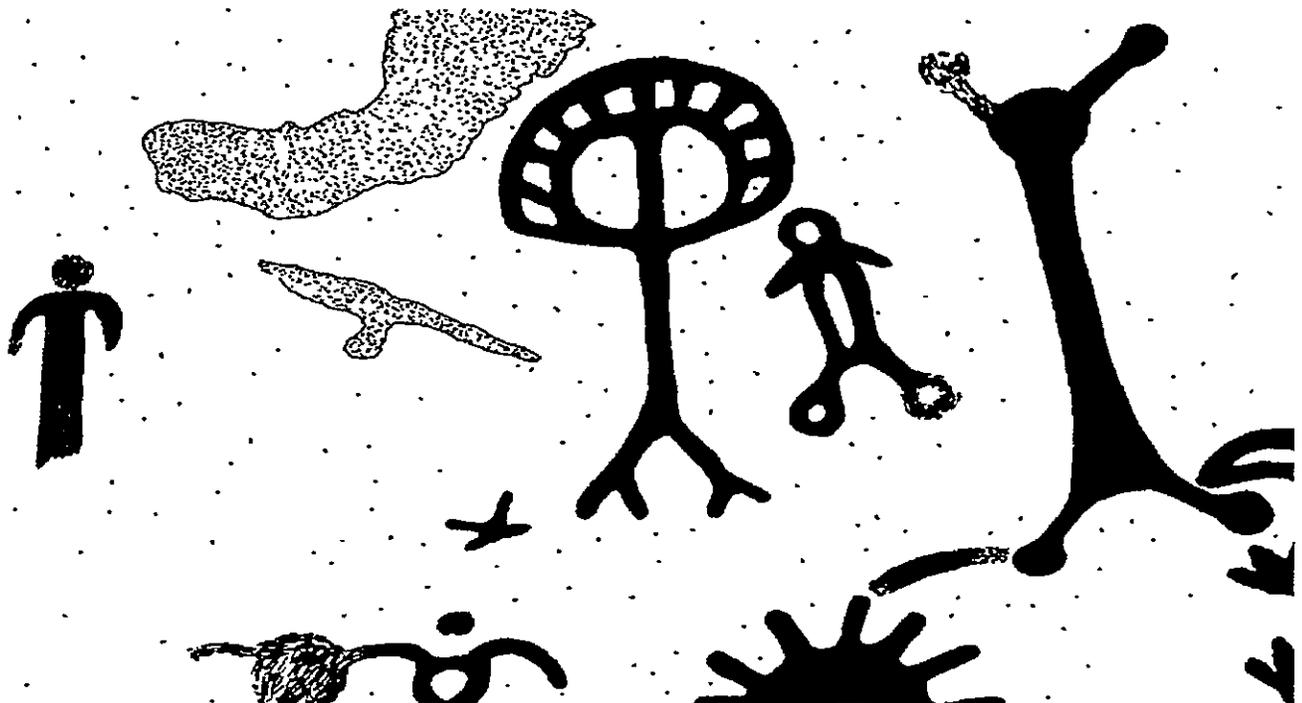

TABLE II-4
INVENTORIED AND REPORTED CULTURAL SITES
1985

Ranger District	Number of Inventoried Sites 1/		Number of Reported Sites and/or Use Areas 2/		Conditions of Remains			Interpretive Value		
	Historic	Prehistoric	Historic	Prehistoric	Poor	Fair	Unknown	Yes	No	Unknown
Chelan	5	2	40	32	20	23	36	23	48	8

TOTAL	167	111	372	199	268	282	299	198	572	79

1/ Includes Forest Service Site Inventories, University/WARC Inventories, State and National Registers.

2/ These include sites situated on adjacent and intermingled private land.

b. Production Potential

The number of sites known and evaluated may represent only a small portion of the total of cultural resources that actually exist on the Forest. Prehistoric and historic land use patterns suggest a high probability for the occurrence of other significant cultural resources within the Forest.

Approximately 90 percent of the identification and evaluation of cultural resources has been carried out in support of the timber sale program. Hence the number of acres currently managed for cultural resource values, which have been determined on the basis of the number and type of significant cultural resources present, is directly related to the acres of timber prescribed for treatment annually.

Recently, increased recreation funding initiated many projects that may adversely impact cultural resources. As lands are allocated to uses involving land and vegetation modification, the probability of adverse impacts on cultural resources also increases. Studies on the Forest indicate certain locations have the greatest probability for overlap between cultural resources and other management activities (Wenatchee National Forest Sampling Design 1983).

As the dimension of land development increases elsewhere, a correspondingly greater proportion of the physical remnants of our American heritage and a large source of scientific data will be irrevocably lost. As a result, the value of cultural sites on National Forest lands will increase with time, intensifying the need to identify, protect, and manage this irreplaceable resource. At the

CULTURAL RESOURCES

same time, because of conflicts with other resource management needs, management decisions will require a multitude of considerations, including factors such as the level of significance of the property, its condition, its suitability for research or interpretive opportunities, accessibility, compatibility with other resource activities, relationship to the local community and/or American Indian concerns, and the like.

c. Demand

The future demand for cultural resources is likely to be a function of three factors: recreational use, the specific association of a community or ethnic group with an historic site or area, and the development and expansion of archaeological and historical research.

With respect to recreation, the Forest receives approximately 4.9 million Recreation Visitor Days use per year (Recreation Information Management 1986). It is thus likely that interpretive programs and designated historic points of interest would experience substantial public use.

The demand for the protection and preservation of historic/cultural sites and areas because of community associations will probably continue at about the same rate as in the past. Salmon La Sac Guard Station, the Liberty Historic District, and Stevens Pass Historic District were all the products of community efforts to recognize historic values embodied in these properties (Wenatchee National Forest correspondence files). Generally, community associations become known as the Forest Service plans for the disposition of the sites and properties. In addition to the local community interest, there is also a widespread expectation by members of the Colville Confederated Tribes and the Yakima Indian Nation that there will be protection of archaeological sites on the Forest. These properties represent a very special link between the Indians and their ancestors who once occupied the Forest lands. This relationship will continue to reinforce the demand for protection and preservation of these sites.

Research by the scientific community is expanding into the uplands, carrying with it the recognition of the exceptional value of hinterland sites to the reconstruction of prehistoric subsistence patterns. Although requests for research are not anticipated to be frequent, the demand for protection of archaeological and historic sites for future research purposes will likely remain high.

4. SCENERY

a. Current Management Program

The Wenatchee National Forest is well known for its outstanding mountain, valley, and lakeshore scenery.

The Cascades landscapes are distinctive in beauty and nature, with sweeping vistas and a variety of topography, ecotypes, and lifeforms. Natural appearing environments exist on much of the Forest, even where intensive commodity management is occurring. Approximately 63 percent of the Forest, including wilderness areas, are in a natural appearing visual condition.

Visual quality is classified according to the scenic variety of an area and how often it is seen by the viewing public. The most scenic classifications are "preservation", "retention", and "partial retention". Definitions of Visual Quality Objectives and percent of land in each classification under current management are depicted in Table II-5.

TABLE II-5
EXISTING VISUAL QUALITY OBJECTIVES
1985

VQO Objectives	Description	Percent of National Forest Land
Preservation (P)	Areas in which only ecological change has taken place except for trails needed for access. They appear to be untouched by human activities.	42
Retention (R)	Areas in which changes in the landscape are not visually evident to the average person unless pointed out. They appear to be natural.	21
Partial Retention (PR)	Areas in which changes in the landscape may be noticed by the average forest visitor but they do not attract attention. The natural appearance of the landscape still remains dominant. They appear to be minor disturbances.	24
Modification (M)	Areas in which changes in the landscape are easily noticed by the average forest visitor and may attract some attention. They appear to be disturbances but resemble natural patterns.	2
Maximum Modification (MM)	Areas in which changes in the landscape are strong and would be obvious to the average forest visitor. These changes stand out as a dominating impression of the landscape. Yet, they are shaped so that they might resemble natural patterns when viewed from 3-5 miles or more distant. They appear to be major disturbances when viewed at closer distances.	11

The most valuable scenery occurs on lands that are distinctive in character and highly visible. The Forest provides the public with seven wilderness areas, six major reservoirs including Lake Chelan, several large natural lakes including Lake Wenatchee, many free flowing rivers, five Washington State "scenic" designated highways, and numerous main travel routes penetrating the Forest toward recreation areas and wilderness. Thirty-four viewsheds and travel routes have been identified as being important recreational travelways on the Forest. Eighteen lakes and reservoirs have been identified as recreational lakes with high visual sensitivities. All major travel routes and lakes are protected with Preservation, Retention and/or Partial Retention Visual Quality Objectives.

b. Production Potential

Table II-31 shows acres by Visual Quality Objective considered to be the maximum protection of scenic values in addition to the acres under the current program.

The following table shows the existing condition of the Forest landscape which would approximate the maximum potential for scenic quality.

TABLE II-6
EXISTING VISUAL CONDITION
OUTSIDE OF WILDERNESS
1984

Description of Visual Condition	Total Forest Lands
Natural appearing landscape	63%
Activities have slightly altered the natural appearing landscape	15%
Activities have altered or heavily altered the natural appearing landscape	21%
Activities have permanently altered the natural appearing landscape (e.g., powerline corridors)	1%

A natural appearing landscape equates with preservation and retention visual quality objectives.

Activities that have slightly altered the natural appearing landscape are associated with partial retention visual quality objectives.

Activities that have altered or heavily altered the natural appearing landscape are associated with the modification and maximum modification visual quality objectives.

c. Demand

Recreation Information Management (RIM) data indicates that approximately 12 percent of the 4.9 million visitor days of recreational use in 1986 was driving for pleasure and viewing scenery. Public demand for scenic quality and concern for its maintenance is increasing and is expected to continue to increase over the foreseeable future. Visual quality concerns are highest along the major state routes that criss-cross the Forest; along collector roads accessing wilderness; adjacent to lakes, rivers, and streams; and in areas near recreation sites or communities.

Recreationists intensively use the five highways, 4,667 miles of existing forest roads, and 2,463 miles of trails. These facilities traverse a wide variety of forest and non-forest lands. Of all these lands, the least potential for impact on the visual resource will be within roadless and commercial forest areas that are delineated as "retention" and "partial retention" in the Landscape Management Inventory.

5. WILDERNESS

a. Current Management Program

Wilderness on the Forest was designated by Congress with the Wilderness Act of 1964 (Goat Rocks and Glacier Peak Wildernesses), the Alpine Lakes Area Management Act of 1976 (Alpine Lakes Wilderness), and the Washington State Wilderness Act of 1984 (Lake Chelan-Sawtooth, Henry M. Jackson, Norse Peak and William O. Douglas Wildernesses). The 1984 Act also added 56,011 acres to the Glacier Peak Wilderness and 13,314 acres to the Goat Rocks Wilderness.

Glacier Peak, Alpine Lakes, Henry M. Jackson and Norse Peak Wildernesses extend across the Cascade Crest into the Mt. Baker-Snoqualmie National Forest while the William O. Douglas and Goat Rocks Wildernesses extend into the Gifford Pinchot National Forest. In the north, the Wenatchee and Okanogan National Forests share the Lake Chelan-Sawtooth Wilderness. Managers of neighboring Forests worked together to develop uniform direction to be used by each Forest for the management of these shared wilderness areas.

Following is the total area for each wilderness area and the amount that lies within the Wenatchee National Forest.

Wilderness	Total Acres	Wenatchee National Forest Net Acres
Lake Chelan-Sawtooth	145,667	56,414
Glacier Peak	576,865	289,001
Henry M Jackson	103,591	27,221
Alpine Lakes	393,360	244,057
Norse Peak	50,923	36,295
William O Douglas	167,195	151,730
Goat Rocks	105,633	36,316
TOTAL	1,543,234	841,034

b. Production Potential

The passage of the Washington State Wilderness Act of 1984 stated that the Secretary of Agriculture was not required to review remaining roadless areas for a wilderness option in the current Forest Plan. Due to this provision, the potential production or supply of wilderness for the 10 to 15 years covered by this plan will be the same as under the current management direction. The use potential for the Wenatchee National Forest portions of the existing Wilderness is 1,146,500 RVDs.

c. Demand

Table II-7 shows the projected demand compared with the potential supply over the planning horizon

The Forest has the capability to meet the projected demand for wilderness use for some time into the future. However, there are some specific areas in high demand which are currently at or above carrying capacity. One such area is the Enchantments within the Alpine Lakes Wilderness

TABLE II-7

WILDERNESS RECREATION USE
ESTIMATED DEMAND AND CURRENT SUPPLY 1/

	DECADE 1	DECADE 2	DECADE 3	DECADE 4	DECADE 5
Estimated Demand (Thousands of RVD's)	423.5	444.7	454.0	477.0	540.2
Potential Supply (Thousands of RVD's)	<-----1,060,000----->				

1/ Support documents are on file in the Forest Supervisor's Office

6. WILDLIFE

a. Current Management Program

The Wenatchee National Forest provides year around or seasonal habitat for an estimated 394 species of wildlife. Of the 394 species, there are 13 amphibian, 18 reptile, 273 bird, and 90 mammal species. The diversity of vegetation types and plant successional stages on the Forest results in a large variety of wildlife habitats. All of these habitats have been considered in the development of this plan.

Proposed, Threatened, and Endangered Species

Federally listed threatened, endangered and those proposed for listing that can be found on the Forest are the bald eagle, peregrine falcon, grizzly bear, gray wolf and the northern spotted owl. Current management for the bald eagle and the peregrine falcon is intended to provide the habitat needed for recovery as listed in the recovery plans. The management direction for grizzly bears is to assess the effects of projects on habitat. On June 23, 1989 the US fish and Wildlife Service issued a rule that northern spotted owl will be evaluated for Federal listing as a threatened species pursuant to the Endangered Species Act of 1973, as amended. This ruling upgrades the status of the spotted owl from that of a Region Six sensitive species to that of a federally proposed species.

Bald Eagle: One active nest site and two suspected nest sites have been located on the Forest. A number of bald eagles winter in the vicinity of and on the Forest. Habitat for nesting and roosting includes areas with mature and old growth conifer stands within 1/2 mile of water.

Peregrine Falcon: No active nest sites have been located on the Forest. At least ten potential nests sites have been located on the Forest. Sightings of single falcons are reported yearly in August through October.

Grizzly Bears: Grizzly bears were once found throughout the Forest but now there are only occasional sightings. There are no known den sites of the bear on the forest. There have been

no confirmed Category 1 grizzly bear sightings on the Forest in recent years.

Gray Wolf: The Forest has received unconfirmed sighting reports of gray wolf; however, there are no known resident populations on the Forest.

Northern Spotted Owl: The northern spotted owl is the only species with a specific management program. This program is to maintain the sites needed to meet standards and guidelines in the Final Supplemental to the Environmental Impact Statement For an Amendment to the Pacific Northwest Regional Guide. There are 43 sites outside wilderness. Active nest sites will be maintained while they are in use. All projects will be reviewed to insure they meet the direction for the spotted owl.

There are 521,000 acres of suitable spotted owl habitat on the Forest. Over 200,000 of these acres have dominant trees over 20 inches in diameter. About 149,000 acres of the suitable spotted owl habitat is in wilderness.

Inventories of spotted owls have been completed over the last four years. These inventories include planned timber sales that have been inventoried for occupancy. Results of these inventories include: 140 sites with spotted owl occupancy; 41 sites had active nests; 30 sites contained pairs; and 69 sites had a single owl.

Sensitive Species

Wildlife species listed as sensitive by the Regional Forester and found on the Forest include: bighorn sheep, Townsend's big-eared bat, Canadian lynx, California wolverine, ferruginous hawk, Swainson's hawk, and the long-billed curlew.

The current management direction for these species is to maintain viable populations and distribution of suitable habitat to prevent them from being listed as Federally threatened or endangered species.

Bighorn Sheep: Three populations of bighorn sheep are known to use the east edge of the Forest. Their habitat includes the steep, open dry

grass/shrub areas, generally below 4000 feet in elevation. Winter range is composed of south facing, open slopes with nearby forest cover.

Townsend's Big-Eared Bat: Boulder Cave on the Naches Ranger District is the only known site on the Forest where these bats are known to exist. There are many rock cliffs on the Forest near this site that contain caves the bats may be using. Population inventories for this species have not been completed.

Canadian Lynx: Canadian lynx have been trapped or sighted on the Forest for many years. The sightings are uncommon with the most recent being on the Cle Elum Ranger District in 1987. Lynx generally use areas of higher elevation dominated by lodgepole pine and subalpine forest.

California Wolverine: There are few reports of wolverine sightings in the Washington Department of Wildlife information system. The species is a resident of boreal forests and is particularly fond of marshy areas.

Ferruginous Hawk: There have been occasional sightings of ferruginous hawks on the Forest. The latest was in the Taneum Ridge area in the fall of 1988. The habitat for this species is found on the east edge of the Forest in dryer, open habitats.

Swainson's Hawk: Occasional sightings of Swainson's hawks on the Forest have been recorded. The habitat for the Swainson's hawk is found on the east edge of the Forest in the dryer sites of open ponderosa pine and Douglas-fir stands.

Long-billed Curlew: There is a limited amount of available habitat for this species on the Forest. The Forest receives few sighting reports of this bird.

Management Indicator Species

Management indicator species are those whose population parameters appear to show the effects of land management practices on specific types of wildlife habitat. This concept has not been used to manage the Forest previous to this plan.

Rocky Mountain elk, mule deer, primary cavity excavators, northern spotted owl, pileated woodpecker, pine marten, northern three-toed woodpecker, mountain goat, beaver, and ruffed grouse are the wildlife management indicator species for the Wenatchee Forest. Current management direction for big game is found in specific management direction for these species in Chapter IV.

Rocky Mountain Elk: There are an estimated 12,600 elk summering on the Forest. For most of the elk herds, summer range is not a limiting factor, however, the summer range for the Colockum herd is a limiting factor. Winter and spring ranges are limiting for the other elk herds on the Forest. The Washington Department of Wildlife feeds an estimated 15 to 30 percent of the elk wintering near the Forest. An estimated 5,600 elk use National Forest winter ranges.

Open roads and the late hunting season on elk put the animals in a highly vulnerable situation during migration. The Forest and the Washington Department of Wildlife have closed roads on the Naches Ranger District to control hunter access and increase the quality of the hunting experience.

Due to the concerns for elk and elk habitat the Forest Service, Rocky Mountain Elk Foundation, and Washington Department of Wildlife are studying the use of habitats by elk.

Mule Deer: An estimated 25,000 mule deer summer on the Forest. The limiting factor for mule deer population in and adjacent to the Wenatchee National Forest is the availability of winter range. The Forest has approximately 106,000 acres of winter range that is used by mule deer, Rocky Mountain elk, and bighorn sheep. An estimated 10,000 deer utilize winter range on the Wenatchee National Forest.

Primary Cavity Excavators: The Forest has approximately 1,451,000 acres that are capable of providing habitat for primary cavity excavators. Of this acreage approximately 807,200 acres are considered not suitable or unavailable for timber management activities. The amount of dead and defective tree habitat in these areas will remain at natural or near natural levels. The remaining habitat will be affected by other resource management.

In some parts of the Forest where private land and National Forest land are intermingled most of the private lands have or will have little or no dead and defective tree habitat. The primary cavity excavator habitat is currently low and will remain so for several decades.

Pileated woodpecker: There are an estimated 300-500 pairs of pileated woodpeckers on the Wenatchee National Forest. They are often found in mature or old growth conifer habitats. The Forest does not have a population or habitat inventory for this species.

Marten/Northern three-toed woodpecker: For management purposes, these two species have been combined. They are generally found associated with mature or old-growth habitats and are not uncommon. The Forest does not have a population or habitat inventory for this species.

Mountain goat: The population of mountain goats is estimated at 1600. They are well distributed across the Forest in a number of sub-populations. Available habitat is estimated at 400,000 acres. This species is sought after for viewing and hunting.

Beaver and Ruffed Grouse: Beaver and ruffed grouse were selected as the management indicator species for riparian habitats. The Forest has an estimated 159,800 acres of riparian habitat. Over 260 species of wildlife use riparian habitat on the Forest. Most of these species require surface water for survival during summer months. Others such as amphibians use the logs and rocks in intermittent streams where there is enough cover to maintain cool, moist conditions. Both the beaver and ruffed grouse prefer deciduous tree and shrub habitats in riparian areas. The Forest does not have a population estimate for these species.

Unique or Special Habitats and Species

Unique or special habitats and species have been identified because of a need to protect them. The habitats and species in this category are: cliffs and rims, ponds, marshes, springs, great blue heron, osprey, goshawks, sharp-shinned hawk, and barred owls (see Chapter III FEIS, Wildlife for more information).

b. Production Potential

Production potential is directly related to habitat quantity and quality. The potential of a species may be achieved by natural processes, through careful planning of resource activities, by using habitat improvements, or a combination of all three. Increasing habitat for one species may often increase habitat for other species, but may also decrease habitat for another group of species.

Table II-8
Production Potential for Wildlife
Proposed Threatened and Endangered Species

Species Name	Estimated Numbers of Species
Bald Eagle	20-50 nests unknown winter birds
Peregrine Falcon	5+ nest sites
Grizzly Bears	20-50 animals
Gray Wolves	1-3 packs
Northern Spotted Owl	150-200 pair

Table II-9
Production Potential for Wildlife
Sensitive Species

Species Name	Estimated Populations
Bighorn Sheep	50-200 animals
Townsend's Big Eared Bat	10-50 colonies
Canadian Lynx	100-200 animals
California Wolverine	Unknown at this time
Ferruginous Hawk	2-5 nests 20-30 birds
Swainson's Hawk	1-10 nests 20-50 birds
Long billed Curlew	Unknown at this time

Table II-10
Production Potential for Wildlife
Management Indicator Species

Species Name	Estimated Populations
Northern Spotted Owl	150-200 pair
Pileated Woodpecker	3,000-4,000 pairs
Marten	3,000-10,000 animals
Northern Three toed Woodpecker	5,000-20,000 birds
Mountain Goats	5,000 animals
Mule Deer	50,000 animals
Rocky Mountain Elk	20,000 animals
Primary Cavity Excavators	90-100% potential population
Beaver	1,000-2,000 animals
Ruffed Grouse	10,000 + birds

c. Demand

Demand for wildlife species on the Forest varies by the type of interest, such as viewing or hunting, and the species itself, such as mule deer and pileated woodpeckers. The tables below display the relative demand for each of the species listed. The rating of High, Moderate, and Low is based on the following:

High - People design outings or trips to see or harvest a particular species and often remark or keep records of their accomplishments.

Moderate - The species is commonly available for viewing or harvesting. No special trips have to be made to view or harvest the animal. People enjoy and remark often when viewing of the animal.

Low - People would like to see the animal but they choose to view it only if it happens in the course of other activities. Not seeing the animal does not cause any further pursuing to see it.

**Table II-11
Demand for Proposed Threatened and
Endangered Species**

Species Name	Demand for Viewing	Demand for Hunting or Trapping
Bald Eagle	moderate	none
Peregrine Falcon	low	high
Grizzly Bear	low	low
Gray Wolf	low	low
Northern Spotted Owl	high	none

Sensitive Species

Sensitive species are either in high demand because they are rare or in low demand because people rarely see them and they are too hard to find .

**Table II-12
Demand for Sensitive Species**

Species Name	Demand for Viewing	Demand for Hunting or Trapping
Bighorn Sheep	high	high
Townsend's Big Eared Bat	low	none
Canadian Lynx	low	low
California Wolverine	low	low
Fisher	low	low
Ferruginous Hawk	high	none
Swanson's Hawk	high	none
Long billed Curlew	low	none

**Table II-13
Demand for Management Indicator Species**

Species Name	Demand for Viewing	Demand for Hunting or Trapping
Northern Spotted Owl	high	none
Pileated Woodpecker	moderate	none

Bobcats	low	high
Moose	high	high

7. FISHERIES

a. Current Management Direction

The Forest has about 241 lakes and reservoirs and 1,770 miles of streams and rivers that support fish. 806 miles of streams and one large lake are available to anadromous fish. Although not confirmed by detailed surveys, it is likely that an additional 260 miles of streams may also provide fish habitat.

Calculation of Recreation Visitor Days (RVD's) in 1986 showed that there were 192,800 days spent fishing or about 580,000 actual fishing trips. Of these, 65 percent or approximately 125,000 days were in roaded areas and 67,000 in roadless areas.

The aquatic habitats support 15 species of cold water game fish and 3 species of warm water game fish (Table II-15). Five species of cold water anadromous and resident salmonoid species account for 95 percent of the angling. Four percent of fishing is distributed among the other cold water species, while less than one percent is spent in warm water fishing.

TABLE II-15

**SPECIES OF GAME FISH
ON THE
WENATCHEE NATIONAL FOREST**

COLD WATER ANADROMOUS	COLD WATER RESIDENT	WARM WATER RESIDENT
Chinook salmon	Kokanee salmon	Smallmouth bass
Sockeye salmon	Mountain whitefish	Largemouth bass
Coho salmon	Pygmy whitefish	Yellow perch
Steelhead trout	Golden trout	
	Cutthroat trout	
	Rainbow trout	
	Lake trout (Mackinaw)	
	Brown trout	
	Brook trout	
	Bull trout (Dolly Varden)	
	Burbot (ling cod)	

A primary management consideration of the Forest is the fishing rights reserved to the Indians by the Yakima Treaty of 1855. The Yakima Indian Nation is concerned that the Forest develops environmental standards which ensure the protection and/or enhancement of the fisheries resource.

-Resident Trout

Resident trout fishing makes up the majority of the recreational fishing on the Forest and, therefore, its continuance is of major concern. Although most Forest streams have very low productivity due to low nutrient content and cold water, recent measurements of rainbow trout in the Yakima River system (mostly below the Forest boundary) indicate one of the best growth rates documented in North America (A Basic Fishery Management Strategy for Resident and Anadromous Trout in the Stream Habitats of the State of Washington, Washington State Department of Game, October 10, 1984). This may be partially due to the long-term reduction in competition with anadromous fish.

Self-sustaining wild populations of resident trout inhabit most of the Forest's streams. Because of heavy fishing pressure on the roaded portions of the Forest, wild resident trout populations are often supplemented with periodic stocking by the Washington Department of Wildlife (WDW). Some popular rivers stocked with catchable adult fish are the Tieton, Wenatchee, Little Naches, Naches, Chiwawa, and Entiat Rivers and Icicle and Peshastin Creeks. WDW also stocks many suitable high altitude and/or previously barren lakes.

There is one sensitive species on the Forest, the bull trout, listed as a Category 2 species by the U.S. Fish and Wildlife Service.

-Anadromous Fish

Four species of anadromous fish, including steelhead trout, chinook, sockeye, and coho salmon, utilize the Forest for spawning and rearing. Numbers of all species except sockeye are less than 10 percent of the historical run levels prior to the construction of irrigation diversions and the mainstem Columbia River dams, and prior to the onset of large commercial fisheries.

The following are the current estimated average anadromous fish escapements attributable to the Forest. Note that some of these returning fish are due to hatchery plants.

TABLE II-16

**ESTIMATED AVERAGE PRESENT
ESCAPEMENT OF ANADROMOUS FISH ON THE WENATCHEE N.F.
(TEN YEAR AVERAGE)**

	Sockeye	Coho	Spring Chinook	Summer Chinook	Steelhead
Yakima River	0	20	865	0	129
Wenatchee River	31,785	0	4,270	1,950	1,104
Entiat River	0	0	859	0	500
Total	31,785	20	5,994	1,950	1,733

b. Production Potential

The Forest has very few detailed stream or lake surveys to evaluate fisheries production and habitat potential. Therefore, numbers or pounds of fish and habitat capability estimates are only a best approximation based on existing knowledge.

It is felt that many streams on the Forest do not have full escapement of anadromous fish, therefore, numbers of returning adults are not necessarily a measure of the ability of the habitat to produce fish. Smolt habitat capability (SHC) is used as an estimate of habitat potential. The following table reflects an estimate of anadromous fish SHC on the Forest.

TABLE II-17

**ESTIMATED EXISTING SMOLT HABITAT CAPABILITY OF ANADROMOUS FISH
WITH FULL ESCAPEMENT ON THE FOREST**

	Sockeye	Coho	Spring Chinook	Summer Chinook	Steelhead
Yakima River	1,500,000 ^{1/}	not	345,000	0	86,000
Wenatchee River	1,795,800	estimated	923,000	645,000	70,000
Entiat River	0		80,000	0	16,000
Total	3,295,800		1,348,000	645,000	172,000

^{1/} Assumes passage provided into Cle Elum system

c. Demand

The demand for fish, and therefore high quality fisheries habitat, is not readily measurable. For anadromous fish, which are commercially harvestable, there appears to be practically an inexhaustible demand. At one time commercial landings of Columbia River fish were over five times their present level, indicating that demand is very high. Treaty rights reserved in the Yakima Treaty of 1855 include considerable demand for increased fish production over the present.

Resident fish demand is also unquantifiable, but very high. To meet a portion of the demand, the Washington State Department of Wildlife has fish planting programs in streams and lakes. There is no indication that there is a limit to the numbers of fish, of appropriate species and size, that could be harvested (Washington Department of Game, James Cummins, personal communication, March 1985).

Due to the high demand for fish, the maintenance, rehabilitation, and enhancement of fish habitat is of primary concern to the public, tribes, and Federal, State, and local governmental agencies.

8a. VEGETATION: TREES

a. Current Management Program

Conifer forest ecotypes occupy approximately 69 percent of the Forest. Elevation, soil types, precipitation and aspect combine to create a wide variety of ecological vegetative types. For simplicity, these can be combined into the three following forest ecotypes which occur on both suitable and unsuitable land:

-Dry Forest

The low elevation, dry sagebrush, bitterbrush, grass type along the east edge of the Forest changes to the ponderosa pine/Douglas-fir zone with increasing elevation and moisture. Pinegrass, elk sedge, kinnikinnick, serviceberry, and ocean spray are some of the common understory plants.

TABLE II-18

**DRY FOREST ECOTYPE
STAND CLASS DISTRIBUTION**

Stand Size Class	Acres	% of Tentatively Suitable Acres ^{1/}
Mature Stands	48,399	6.1
Immature Two-Storeyed Stands	106,828	13.5
Pole Stands	91,013	11.5
Seed and Saplings	47,488	6.0
Bare Ground	1,123	.1
Subtotal	294,851	37.2

-Wet Forest

The wet forest zone is characterized by a wide variety of plant species. Ponderosa pine and Douglas-fir may be present, but without disturbance they will gradually be replaced by shade tolerant grand fir, silver fir, western hemlock, or western red cedar. Less abundant, but highly valued trees because of their wood and aesthetic qualities, are western larch, noble fir and western white pine. At the upper elevations in this zone lodgepole pine, mountain hemlock, subalpine fir, and Englemann spruce become more prevalent.

TABLE II-19

**WET FOREST ECOTYPE
STAND CLASS DISTRIBUTION**

Stand Size Class	Acres	% of Tentatively Suitable Acres 1/
Mature Stands	191,904	24.2
Immature Two-Storeyed Stands	127,201	16.0
Pole Stands	134,323	16.9
Seed and Saplings	37,269	4.7
Bare Ground	8,162	1.0
Subtotal	498,859	62.8

1/ See Table II-22

**-Sub-Alpine Parkland and
Mountain Meadows**

This zone is best known for its wide variety of flowering herbs and forbes. Parklike stands of whitebark pine, Englemann spruce, subalpine fir, and alpine larch adjoin the barren or treeless upper mountain slopes. Much of this zone is in wilderness.

In both the dry and wet zones the most common conifer species is Douglas-fir. However, old-growth ponderosa pine receives the most interest from local sawmills. Douglas-fir and ponderosa pine make up 50 percent of the existing volume of timber on the Wenatchee. The 16 species of conifers in order of standing volume from the 1977 Forest inventory are:

TABLE II-20

**STANDING VOLUME OF WENATCHEE
NATIONAL FOREST CONIFER SPECIES**

Species	% Standing Volume
Douglas-fir	37%
Ponderosa pine	13%
Pacific silver fir	11%
Grand fir	7%
Lodgepole pine	6%
Western hemlock	5%
Subalpine fir	5%
Western larch	5%
Mountain hemlock	4%
Englemann spruce	3%
Western white pine	2%
Western red cedar	1%
Alaska yellow cedar	1%
Noble fir	
Whitebark pine	
Subalpine larch	

The current timber harvest level as revised after the Washington State Wilderness Act is:

	Million Board Feet	Million Cu. Ft.
Annual sale quantity	170.9	31.4
Unregulated volume	5.9	1.0
	176.8	32.4

b. Production Potential

Of the 2,164,180 acres of Wenatchee National Forest, 37 percent or 791,899 are tentatively suitable for timber production. These lands are capable of growing industrial wood and are available and suitable for timber management activities. Table II-22, summarizes Forest land suitability for timber production. (For details of the suitability process see Field Review Timber Land Suitability, Wenatchee National Forest, 1984.)

TABLE II-22
TIMBER LAND SUITABILITY
ACRES

	Not Suited for Timber Production	Totals

1. Lands classified as unsuitable	137,717 ^{2/}	
2. Lands classified as suitable		(6,148) ^{3/}
3. Lands classified as separate suitability component	0	
C. Irreversible resource damage (219.14(a)(2))	18,720	
D. Regeneration Difficulty (Reforestation cannot be guaranteed) (219.14(a)(3))	65,933	
E. Regeneration difficulty-lands classified as a separate suitability component	0	
IV. Tentatively suitable Forest Land		791,899
V. Total of Nonsuitable Land	1,372,281	

^{1/} Includes Alpine Lakes Management Area Non-harvest land allocations

^{2/} Due to reforestation difficulty

^{3/} Currently producing less than 20 cubic feet, but can be reforested

When legal and other requirements are met, the suitable lands would be reduced to 689,918 acres. These would have a maximum production potential of 36.5 million cubic feet, or 186.6 million board feet, per year (TSPQ). The ASQ is 34.1 million cubic feet, or 173.8 million board feet per year.

c. Demand

The demand for wood products from the Wenatchee National Forest in the 1989-1999 decade is obviously difficult to predict. Such influences as the national economy, Canadian log imports, housing starts, exports to Pacific-rim countries, etc., are outside of regional and local control. Other more specific factors will, or could, affect the Forest's programmed harvest and the local wood products industry. These are the effects resulting from: rulings from "old growth" and "Spotted Owl" appeals and court decisions; significant changes in Congressional and Administration direction regarding budgets and targets (outputs); and delays or constraints from new emerging issues which undoubtedly will surface.

Certain localized situations will also have an effect. These include: the accelerated harvest of commercial timber on the private lands ("checkerboard" ownership) within the Forest by Longview Fibre, Boise Cascade, and Plum Creek Timberlands in the next ten years; the potential phase out of antiquated sawmills and the possible construction of new facilities; the continued sale of large volumes of timber by the Yakima Indian Nation from their reservation lands; and the continued close and intense scrutiny of many Forest Service projects by local publics. The various factors influencing the demand for wood products are often conflicting.

It is very probable that the demand for logs from the Wenatchee for the coming decade will continue to be close to the long-term average cut of about 168.6 million board feet per year. During this same period, the sell volume target was 175.9 million (MM) board feet per year, and the average sell was 173.3 MM board feet. The Forest has an uncut timber volume under contract (as of October 1988) of 370 MM board feet. This is a significant reduction from the 850 MM board feet under contract in 1985. This reduction in volume under contract is due to the Timber Relief Act,

and accelerated harvest to meet increase in demand for wood products.

The accelerated harvest of timber from private lands is affecting, and will continue to affect, the demand for timber from the National Forest. Both Longview Fibre and Plum Creek export a significant amount of their logs to the Pacific-rim countries. The pine, smaller logs, and logs which are not "marketable" to export customers at a particular time, are generally sold locally to purchasers who also rely on National Forest timber. The greater the harvest of the major private landowners, the greater is the supply of logs to others. It is very reasonable to assume their activity will continue at a high rate during the decade.

In addition to the private landowners, the Yakima Indian Nation will continue to make timber readily available to traditional purchasers of National Forest timber. They have harvested heavily in the Yakima Basin and are major suppliers of timber to local industry. Their large timber sales will apparently continue because they have become a very important and lucrative source of income for the Nation. In addition, the Nation could understandably view any increase in National Forest timber sales as competition to their own sales. Bureau of Indian Affairs volume for eastern Washington is estimated to be 479 MM board feet per year. This is down approximately 50 MM board feet per year from harvested volumes of the past decade (Larson, 1982). The Washington Department of Natural Resources (DNR) proposed volume from Eastern Washington is 87 MM board feet annually thru 1993 (DNR, 1983). If stumpage prices increase, there exists a strong potential of an increase in yield from other private lands. The Department of Natural Resources projects a strong increase in volume from other private lands that may equal the decreases in forest industry and public timber supplies.

Because of the long distances to major pulp and paper facilities, demand for low quality and small size material has historically been low. Under the 1963 Wenatchee Working Circle Plan, these materials were not counted in calculating the proposed harvest. Since 1963, new industries utilizing smaller logs have been installed in Entiat, Cashmere, Yakima, Ellensburg and Naches.

There also are small business enterprises engaged in producing house logs for homes and cabins. Current central Washington annual mill capacity is 314 MM board feet. Historically such mills rely on the Wenatchee National Forest for approximately 60 percent of their production. This dependency by individual mills ranges from 40 percent to 100 percent (telephone survey, Walk, 1985). Higher prices for quality timber at west side mills often results in the best quality logs being transported to the Puget Sound area. In addition to the log supply for central Washington, a 1980 mill survey found over 13 MM board feet from the Wenatchee going to Puget Sound area mills annually (Socio-Economic Overview, 1982).

The apparent excess demand over supply as measured by full mill capacity is strongly dependant upon price. At low stumpage prices, this would be a good measure of demand. However, when prices rise, some of the more inefficient capacity is not utilized.

In summary, the best estimate of the future demand for wood products appears similar to the harvest level during the past decade. There are no indications that there will be a surge of new mill capacity developed in the area or new markets developed outside the existing area. Any changes in mill facilities will likely be a replacement of antiquated operations with state-of-the-art mills. The exception would likely be the increased utilization and marketing of lodgepole pine and other small diameter logs. Chelan County would be the logical place for an increase in capacity particularly if it were small businesses. The current situation calls for a high market share for small business, but small business manufacturing limited to small quantities and specialty products. The significant amounts of timber volume available from Longview Fibre, Boise Cascade, and Plum Creek lands, as well as continued sales from the Yakima Nation, should make timber supplies readily and competitively available for the first decade. It appears that the second decade is when demand for National Forest timber may increase significantly.

Public demand for firewood permits increased rapidly on the Forest from 1973 through 1981. Introduction of a charge permit system in 1982 resulted in a temporary decrease in permits.

However, in 1984 nearly 10,000 permits were sold, an 8 percent increase over 1983. Income in 1984 from wood permits (four cords for \$10, with a 10 cord maximum) was \$119,745. In 1985, there was approximately 27,000 cords sold with an income of \$151,000. Demand is projected to level off as the quality of available wood decreases.

8b. VEGETATION: FORAGE

a. Current Management Program

The total annual forage production on the Forest is estimated to be 336,000 tons. One-third, or 112,000 tons, is located on steep slopes and 10 percent of this production is considered available to wildlife only. Of the remaining 224,000 tons, reductions are made for plant survival and soil and watershed protection. The total amount available to wildlife and livestock is 65,000 tons or 130,000 Animal Unit Months (AUM's). In 1988, there were 20,900 AUM's used by livestock which allowed 109,100 AUM's for wildlife.

Of the 2,164,180 acres within the Forest, 18.5 percent, or 401,100 acres, is within vegetation types and on slopes suitable for grazing by livestock. There are an additional 500,871 acres outside of wilderness potentially capable of providing livestock forage following silvicultural practices such as regeneration harvests or thinning. The current management potential of the Forest to provide forage for livestock has been calculated at 37,031 animal unit months annually.

Current inventoried range allotment boundaries do not include all of the available and suitable range resource on the Forest (see Table II-23).

b. Production Potential

After considering legal and other requirements the maximum production potential for livestock is between 38,000 to 43,000 animal unit months annually, depending on the amount of temporary range created through vegetative manipulation.

TABLE II-23
SUITABLE RANGELANDS 1/ AND ANIMAL UNIT MONTHS
AVAILABLE TO LIVESTOCK 2/

	Number of Allotments	Suitable Rangelands (Acres)	Percent of Suitable Rangelands	Percent of Total National Forest Acres	Estimated Livestock Grazing Capacity (AUM)	1988 Actual Use (AUM)	1988 Livestock Numbers
Inventoried Commercial Livestock Allotments (Cattle, Sheep, and Horses)	40	182,742	45.5%	8.4%	23,210	18,499	1,984 Cattle 8,607 Sheep 87 Horses
Inventoried Recreation Livestock Allotments	36	20,719	5.2%	1.0%	4,307	2,377	13,550 Head Recreation Livestock
Sub Total in Allotments	76	203,461	50.7%	9.4%	27,517	20,876	---
Suitable Range Outside Inventoried Allotments and Outside Wilderness	---	197,639	49.3%	9.1%	9,514	---	---
Total Forest	76	^{3/} 401,100	100.0%	18.5%	37,031	20,876	---

1/ Suitable Rangelands are those areas currently producing forage suitable for livestock use on lands less than 60 percent slope.

2/ Animal Unit Month capacities are for livestock only. Total production in pounds per acre have been reduced to reflect needs of wildlife, soil, and watershed protection, in addition to the plant needs.

3/ There are an additional 500,871 acres outside of wilderness that have potential to contribute to the suitable rangeland base after timber has been harvested.

c. Demand

The "Wenatchee National Forest Socioeconomic Overview" discusses the difficulty of projecting demand due to past variability of the livestock industry. However, it estimates the demand for grazing on the Forest will increase slightly above current levels over the next ten years.

Demand for cattle grazing is expected to be greater than the one to two percent projected increase after the first decade.

The demand for sheep forage is more difficult to project. National demand is down and this trend is expected to continue indefinitely. Locally permitted numbers on the Forest have fluctuated year to year over the past six years. Based on the Five Year Grazing Statistical Report, sheep numbers were down slightly between 1975 through 1980. However, numbers for 1984 were higher than the 1975 level. The demand for sheep grazing on the Forest is expected to remain at or slightly above current levels for the next ten years.

8c. VEGETATION: UNIQUE ECOSYSTEMS

a. Current Management Program

The Tumwater Botanical Area was established under Regulation T-9(I) on June 10, 1938, for the protection of Lewisia tweedyi. The 1,104 acres was redesignated in 1971 as a botanical area under 36 CFR 251.22 to be managed in a near natural area to protect plant species which occur there.

Although the area is located along a major highway, it is rather inaccessible due to the steep, rugged terrain. It is usually visited only by people who wish to view or study the unusual species that inhabit the area including: Lewisia tweedyi, Hackelia venusta, Silene seelyi, and Chaenactis ramosa. The area is within Sections 28 and 34, T.25N., R.17E., P.M.W, and is approximately four miles north of Leavenworth, Washington, in the Tumwater Canyon.

b. Potential Areas

The following four additional Botanical Areas and four Geologic Areas are proposed for protection by some publics.

Camas Botanical Area - Located on the Leavenworth Ranger District in Section 32, T. 23 N., R. 18 E., and Section 4, T. 22 N., R. 18 E., and is approximately 800 acres in size. Protection is proposed for Delphinium viridescens, Wenatchee Larkspur, which is one of two State and Federal candidates to the endangered species list.

Gene Creek Botanical Area - Located on the Entiat Ranger District in Sections 8, 17, and 20, T. 27 N., R. 20 E., and is 1,930 acres in size. Protection is proposed for a ponderosa pine ecosystem containing old-growth dependent animals and plants.

Hornet Ridge Botanical Area - Located on the Entiat Ranger District in Sections 4,5,6, and 10, T. 26 N. R. 19 E., and is approximately 2,100 acres. Protection is proposed for the park-like stands of ponderosa pine containing old-growth dependent animals and plants.

Lake Creek Botanical Area - Located on the Entiat Ranger District in Sections 27, 28, 33, and 34, T. 29 N., R. 19 E., this area is 212 acres. Protection is proposed for plants associated with an undisturbed wetland habitat.

Kloochman Rock Geologic Area - Located on the Naches Ranger District in Sections 4, 5, 8, and 9, T. 13 N., R. 14 E., it is approximately 340 acres. Protection is proposed for a unique geologic feature.

Goose Egg Mountain Geologic Area - Located on the Naches Ranger District in Sections 31 and 32, T. 14 N., R. 14 E., and Sections 5 and 6, T. 13 N., R. 14 E., it is approximately 635 acres. Protection is proposed for this unique geologic feature.

Rimrock Geologic Area - Located on the Naches Ranger District in Sections 25 and 36, T. 14 N., R. 13 E., and Sections 30 and 31, T. 14 N., R. 14 E., it is approximately 425 acres in size. Protection is proposed for this unique geologic feature.

Blue Slide Geologic Area - Located on the Naches Ranger District in Sections 28, 29, 32, 33, and 34, T. 13 N., R. 13 E., and Section 4, T. 12 N., R. 13 E., and it is approximately 740 acres. Protection is proposed for this unique geologic feature.

8d. VEGETATION: THREATENED, ENDANGERED, AND SENSITIVE PLANTS

a. Current Management Program

The Forest has a large variety of uncommon and unusual plant species. These species exist here because of atypical geologic substrates, various past glacial activity and the past and present climatic regimes.

Soil parent material formed from serpentinite and sandstone result in unique habitats for plants that are found no where else. The northern part of the Forest was affected by continental glaciation while the southern part was not. This has multiplied the number of possible habitats thereby increasing the variety of plants species. The results of this differential glaciation has made the mountains around Wenatchee the home of some of the most unusual plants in the state. Finally,

climatic regimes on the Forest are numerous; ranging from a near continental climate in some areas to essentially a maritime climatic pattern in other places.

Although there are no known Federally listed threatened or endangered plant species on the Forest there are 50 plants on the Region 6 sensitive plant list (Table IV-10, Chapter IV). Of these 50 species, 7 are candidates for proposal for listing as endangered or threatened and the remaining are listed by the State of Washington.

The extent of the populations of Threatened, Endangered or Sensitive (T, E or S) species on the Forest is not fully known. Therefore, before a project is initiated, inventories to determine the presence and extent of these species in the project area are conducted on a priority basis. Forest Service policy requires the maintenance or enhancement of all populations of T, E or S species. All necessary measures are taken to assure that management activities do not adversely affect these species.

8e. VEGETATION: RESEARCH NATURAL AREAS

a. Current Management Program

Research Natural Areas (RNA's) are part of a Federal system of tracts established for non-manipulative research and educational purposes. Each RNA is a site where some features are preserved for scientific purposes and natural processes are allowed to dominate. Their main purposes are to provide: (1) baseline areas against which effects of human activities can be measured; (2) sites for study of natural processes in undisturbed ecosystems; and (3) gene pool preserves for all types of organisms, especially those which are classified as rare and endangered (Dryness, et al. 1975, also see Forest Service Manual 4063.02).

Prior to establishment, a comprehensive Establishment Record is made. For RNA's proposed on National Forest System lands, the Record is submitted to the Chief of the Forest Service for approval.

Established RNA's

There are two established RNA's on the Forest. Meeks Table RNA on the Naches Ranger District is 64 acres and represents the ponderosa pine/ pine grass plant community with a co-dominance of Douglas-fir. It was established on July 7, 1948, and is now within the William O. Douglas Wilderness.

Thompson Clover RNA located in Swakane Canyon on the Entiat Ranger District is 276 acres in size and exemplifies a plant community characterized by Thompson Clover. It was established on February 17, 1977.

Formally Proposed RNA's

The Research Natural Area Committee for the Pacific Northwest has formally proposed two additional RNA's. Eldorado Creek located in the Teanaway drainage of the Cle Elum Ranger District is 1,336 acres in size and represents a plant community found on serpentine derived soils. The Eldorado Creek area was designated as a Special Area (Proposed RNA) in the Alpine Lakes Management Plan (November 2, 1981).

Fish Lake Bog on the Lake Wenatchee Ranger District is a 106 acre area on the west end of Fish Lake near Lake Wenatchee. This represents a floating bog community.

Preliminary Establishment Records have been made for both of these areas; Fish Lake Bog on July 5, 1979, and Eldorado Creek on August 9, 1972. A supplemental report on the mineral character of the proposed Eldorado Creek RNA was made on November 6, 1974.

b. Potential Program

Recommended RNA's

The Research Natural Area Committee for the Pacific Northwest Region determined that the candidate RNA's listed in Table II-24 represent the best examples of particular kinds of natural ecosystems in the Region and are needed to meet present and future demands. There may be some

future RNA needs that can best be satisfied on the Wenatchee National Forest. When suitable new areas are identified, they will be considered for addition to the Research Natural Area inventory.

TABLE II-24
RECOMMENDED RESEARCH NATURAL AREAS
1984

Name	Area (Acres)	Location (District)	Plant Community Exemplified
* 1. Cedar Creek	2205	Naches	Mixed old-growth conifer/shrub forest and Pacific silver fir forest.
** 2. Icicle/Frosty Creek	784	Leavenworth	Western red cedar/western hemlock forest.
** 3. Chiwaukum Creek	1124	Leavenworth	Grand fir mixed old-growth conifer/shrub
4. Drop Creek	530	Cle Elum	Englemann Spruce/Subalpine fir forest

* Within the William O. Douglas Wilderness

** Within Alpine Lakes Wilderness

Steps in Establishment of RNA's:

1. R-6 Research Natural Area Committee working in conjunction with the Washington Natural Heritage Plan (Department of Natural Resources, 1985) identifies the need for a site representing a specific natural ecosystem.

2. This committee then works with the area ecologist and ranger district personnel to identify several potential representative sites.

3. The committee visit and evaluates the sites and narrows the list down to the most representative site.

4. This site is then recommended through the Forest Plan for establishment as an RNA.

5. If the area is allocated as a proposed RNA by the alternative in the Forest Plan which is implemented, then an establishment report is devel-

oped. In the past, ranger district personnel have worked with personnel from the Pacific Northwest Forest and Range Experiment Station in the development of this report.

6. The approval procedure for an RNA Establishment Report is as follows:

- District Ranger - Review and Recommend
- Forest Supervisor - Review and Recommend
- Pacific Northwest Station Director - Review and Recommend
- Regional Forester - Review and Recommend
- Director of Division of Recreation - Review and Recommend
- Deputy Chief of Research - Review and Recommend
- Chief, U.S. Forest Service - Approve

7. Upon approval by the Chief, the area is designated as a Research Natural Area and will be managed accordingly.

**8f. VEGETATION: ENTIAT
EXPERIMENTAL FOREST**

a. Current Management Program

The Entiat Experimental Forest includes 4,620 acres of Forest lands located within the Entiat River drainage northwest of Wenatchee, Washington. Research has been conducted on the area since 1957; in 1971, it was formally designated as an Experimental Forest. The Pacific Northwest Forest and Range Experiment Station and the Wenatchee National Forest cooperatively administer the area with the primary goal of providing opportunities for studying the effects of forest management and fire on vegetation, soil, and water resources. The area was selected as being representative of steep, forested watersheds occurring along the east slope of the Cascades. It consists of three similar, contiguous watersheds ranging in size from 1,168 acres to 1,393 acres, and in elevation from 1,800 feet to 7,000 feet. The mean slope is 50 percent with slopes as steep as 90 percent.

A major wildfire which burned most of the area in 1970 has had a dramatic impact on Forest vegetation. Pre-fire vegetation was primarily undisturbed, mature forest with small, subalpine grass-forb openings and bare rock. About 75 percent of the Forest was classed as ponderosa pine, with Douglas-fir the main associated species. Thickets of dense lodgepole pine occurred on wetter sites at higher elevations. Important understory species included bitterbrush, snowbrush ceanothus, pinegrass, and numerous forbs. Fifteen years after the fire, the vegetation consists of a mosaic of shrub fields intermixed with planted pine and fir, and dense, young stands of naturally-established lodgepole pine. Scattered remnants of unburned old-growth forest occur on rocky ridges and outcrops.

The original research plan for the experimental watersheds was to develop baseline information on climate and hydrology under natural conditions, then test for changes following the construction of roads and implementation of several timber harvest practices. The collection of this information and the preparation of harvest plans were nearly complete when the watersheds burned.

Fire is a common occurrence in this Forest, hence research objectives were quickly changed to utilize the preburn data to evaluate effects of fire on the environment and the alteration of those effects by the re-establishment of forest vegetation. Initial postfire studies provided land managers, resource specialists, and scientists with a better understanding of the hydrologic response of burned watersheds including water yield and physical water quality; chemical water quality and site productivity in response to wildfire and erosion control fertilization, natural vegetation recovery and the effectiveness of erosion control seeding and fertilization treatments; soil and water responses to several methods of timber salvage; and effects of a large wildfire on local and regional economics.

9. WATER

a. Current Management Program

The Forest is an extremely important source of high quality water for all types of uses. The water produced on the Forest maintains components of the natural ecosystem, including vegetation, fish and wildlife. Water also serves the administrative needs of the Forest Service and is used both on and off Forest for domestic, municipal and industrial purposes, stock watering, irrigation, power generation and recreation.

The majority of the Forest lies within four sub-basins of the Columbia River Basin: Chelan, Entiat, Wenatchee and Yakima Rivers. There are an estimated 3,600 miles of perennial streams on the Forest, with 806 and 963 miles of Class I and II streams, respectively. The Forest contains hundreds of lakes, ponds and springs that receive a variety of uses. There are an estimated 57,000 acres of lakes and reservoirs on the Forest.

Sampling of water quality to monitor background levels and effects of management activities began on the Forest in 1966. Monitoring of the Forest's 25 major watersheds between 1967-1980 involved nearly 20,000 samples. This data suggest that the Forest has been complying with State water quality standards; however, some measurements document conditions outside of these standards.

WATER

Refer to the Forest Water Quality Data Summary (in preparation) for details regarding this water quality data base.

The goal of project planning and implementation on the Forest has been to meet or exceed water quality standards and the State's Forest Practices rules and regulations. Regional recertification of Forest Service management practices is needed now in order to evaluate compliance of these practices with the recent major revisions of the State Forest Practices Rules and Regulations.

b. Production Potential

The Forest annually contributes approximately 4.455 million acre feet of high quality water to area streams, rivers, lakes, reservoirs and ground-water aquifers. Runoff is orderly in most years with two typical annual peak flows--the highest in late May and a secondary peak in July. Maximum peak flood volumes historically occur in December, often associated with temperature inversions and rain-on-snow events. Unregulated runoff during low flows is sustained by the gradual melting of the winter snow pack.

Water benefits and utilization are enhanced through regulation facilities such as reservoirs operated by the Bureau of Reclamation. Summer streamflows are enhanced in several areas on the Forest through releases of stored water from six major reservoirs for irrigation and power production. The mean annual storage for these six impoundments over the 10 year period between 1967 and 1977 was 1,360,800 acre feet.

Water yield increases result from vegetation manipulation, such as timber harvest. However, these increases are only temporary (less than 20 years) unless the land use changes, as with a conversion of timber to pasture land. The amount of change in total yield is often overstated. Yield increases due to timber harvesting are masked by the large magnitude and variability of natural water yield.

c. Demand

Water has a primary importance for all types of uses both on and off the Forest. The water on the Forest is essential for maintaining components of natural ecosystems, including vegetation, fish and wildlife. High water quality is important for a healthy aquatic environment necessary for maintaining populations of resident and anadromous fish on the Forest. Many recreational activities are directly or indirectly water based such as fishing, boating, camping and sight-seeing. Streams and lakes on the Forest are heavily used for sport fishing.

Forest watersheds provide 95 percent of the water used for irrigation and domestic water systems in Chelan, Kittitas, and Yakima Counties. This region has a long growing season with productive soils upon which many potentially valuable crops are grown. The downstream use of water emanating from the Forest has continued to increase dramatically over the past two decades. The Yakima Basin irrigators diverted 2.4 million acre feet of water to produce a crop value of \$234,500,000 from 225,225 acres in 1981. (Source: 1981, Crop Production Reports--Yakima and Columbia Basin, Bureau of Reclamation).

Existing and foreseeable water shortages in the lower Yakima River are being identified through the on-going water rights adjudication in that sub-basin. It is improbable that potential irrigation water requirements on the Yakima Indian Nation Lands will be met with existing water storage facilities. Additional storage development would be required to produce an additional 200,000 acre feet annually. Most of this development would occur on the Forest, affecting a wide range of other resources. At present, conservation measures pose a more cost effective and environmentally sound approach to water use management in the drainage.

Forest watersheds provide domestic water for cities, small communities, organization sites, special use summer homes, and recreation areas. Municipal watersheds on the Forest are managed for the complete range of multiple use activities. Water emanating from these drainages must be suitable for domestic use with cost effective treatment procedures. In most cases, the application

of multiple-use management will provide the needed protection of water quality in municipal watersheds.

Instream flows within the National Forest boundary have not been a critical issue. The Forest currently has sufficient stream discharge emanating from unregulated water sources so that requirements for instream or minimum flows on the Forest are not anticipated in the short term. There has been some concern regarding the potential impact of proposed small hydroelectric projects to reduce streamflows to a volume that could adversely affect channel maintenance processes and aquatic habitat.

Current Forest resource management activities require water use at nearly 825 designated points of use. All non-Reserved Forest water uses have Certificates of Water Rights or have applications pending with Washington State's Department of Ecology.

10. SOILS

a. Current Management Practice

The soils and all related soil properties on the Forest are highly variable, depending on the interaction of climate (precipitation and temperature) topography (slope, aspect, and elevation), parent material, organisms (both vegetative and animal), and the length of time that the soils have been in place. Soil supports and forms the base for all components of the natural ecosystem. Forest soils act as the sponge that holds and cleanses large amounts of water that is so important for the maintenance of natural ecosystems and for public domestic, agricultural, recreational, and power uses.

The soils on the Forest fall into three general categories: those that are residual (formed in place); those that have been transported by ice or water (glacial till, outwash, alluvium, etc.); and those that have been transported by air (pumice, volcanic ash, loess, etc.). Most of the soils on the forest have been influenced by and have at least some volcanic ash in the surface horizon. In the northern part of the Forest (east of Glacier Peak)

there is a large block of soils that have formed in deep deposits of volcanic ash and pumice. Most of the major river basins on the Forest have been influenced by alpine glaciation, the effects of which are much more pronounced in the northern half of the Forest. All of the transported materials overlay something else, so that these soils all tend to be younger than most of the soils that have formed in residuum (formed in place from bedrock). Bedrock materials from which soils have formed include: basalt, andesite, rhyolite, granite, granodiorite, schist, gneiss, sandstones, and pyroclastics. In fact, there are sub-divisions (geologically) of many of these major rock types, so the variation in soil properties caused by geologic differences are wide.

Most of the granitic materials are located in the northern part of the Forest, and most of the extrusive igneous (basalt, andesite, etc.) occur in the southern part of the Forest. The sedimentary (sandstones) occur in the mid and southern parts of the Forest.

b. Demand Potential

The demand is great to maintain productive soils that can support other resources. Maintaining soil productivity is mandated by the National Forest Management Act. Minimizing soil erosion and soil compaction, along with maintaining or enhancing soil nutrient level, is very important if this is to be achieved.

11. AIR

a. Current Management Program

The management of air as a resource for which the Federal Land Manager has responsibility has developed rapidly in the past twenty years. The Clean Air Act (CAA) 1967 and the amendments to the Act (1972 and 1977) have mandated that managers of the National Forests take specific actions in conjunction with other Federal, State, and Local agencies to maintain or improve air quality.

The Environmental Protection Agency (EPA) was assigned the responsibility to develop the National Ambient Air Quality Standards (NAAQS). The states became responsible for developing a State Implementation Plan (SIP) to maintain or improve air quality. The 1977 supplement required the states to add a section to their SIP which addressed the Prevention of Significant Deterioration (PSD) as well as visibility within the Federally designated Class I areas (See Section 162 CAA, August, 1977, for a definition of Class I areas). The continuing evolution of this legislation has guided the development of the Air Resource Management Program on the Wenatchee National Forest.

The managers of the Forest have worked with the State of Washington to ensure our resource management projects are in compliance with the SIP. Most of the work has been to assure that our prescribed fire program complies with the direction outlined in the SIP. One of our major efforts has involved the protection of visibility within the three Class I Areas (Alpine Lakes Wilderness, Glacier Peak Wilderness, and Goat Rocks Wilderness) on this Forest and those Class I areas adjacent to this Forest. These efforts have developed to where smoke management is now an integral part of our prescribed fire program.

During the past two years funding has become available to begin the design of a process to measure Air Quality Related Values (AQRVs). The Alpine Lakes Wilderness has been picked as the pilot Wilderness in the Pacific Northwest for which baseline data on the chemical composition of the atmosphere will be collected. It is expected that the first measurements will occur during the 1989 field season.

The monitoring of visibility has been on going since 1983, and several sites have provided data that is applicable to the Class I areas on this Forest.

Interagency Air Resource Management continues to become a larger part of the Forest Management Program. During the next few years a rapid increase in the site specific data available regarding the chemical composition of the Forest's Air resource is expected.

b. Production Potential

We currently do not have the skills available to attempt to quantify the amount of clean air "produced" on the Forest. Future quantification of the potential to change the chemical composition of the atmosphere may influence our vegetative management practices.

c. Demand Potential

The value of clean air is being realized in our society. As urbanization increases in the Puget Sound the public is expected to demand that the forests be managed in a manner that view air as an essential component of the resource base and mandate that our National Forests be managed in a manner that provides this resource in much the same manner that it is expected to provide clean water.

12. MINERALS

Overview

The geology of the Forest is lithologically, mineralogically and structurally very complex. Because of its geologic complexity, the Forest has potential for the occurrence of a variety of mineral resource commodities including, but not limited to, gold, silver, copper, lead, zinc, geothermal, coal, limestone, asbestos, garnet, pumicite, oil and gas, etc. Because mineral commodities are classified by law into three distinct groups (locatables, leasables, and salables), the way each group is

managed and the authority of the Forest Service to control the exploration for and development of each commodity varies somewhat. However, the management objectives for all three types of mineral resources is the same and is summarized as follows:

1. Encourage and facilitate the orderly exploration, development, and production of mineral and energy resources within the National Forest System in order to maintain a viable, healthy minerals industry and to promote self-sufficiency in those mineral and energy resources necessary for economic growth and the national defense.

2. Ensure that exploration, development, and production of mineral and energy resources are conducted in an environmentally sound manner and that these activities are integrated with the planning and management of other National Forest resources.

3. Ensure, that lands disturbed by mineral and energy activities are reclaimed for other productive uses.

a. Locatable Minerals

1) Current Management Program

Examples of locatable minerals occurring on the Wenatchee National Forest include, but are not limited to, copper, gold, molybdenum, iron, chromite, nickel, zinc, silver, lead and uncommon varieties of limestone, gemstones, and other minerals that have unique and special values. Forest Service control is accomplished by reviewing plans of operation in a timely manner, by approving only those activities that are reasonably necessary for the proposed operation, by ensuring environmental protection standards are met, and by ensuring that prompt reclamation of disturbed areas is accomplished.

The Forest has approximately 11,000 mining claims covering 200,000 acres properly recorded. Only a very limited number of these claims will actually experience exploration and development activities. At present, even though there is a relatively high amount of on-going exploration, prospecting and mineral related recreation activities, mineral production activity from the Forest is relatively minor in scope.

Designated wilderness areas and other withdrawn areas are not open to mining claim location. Such areas presently constitute about 42 percent of the total Forest area. These areas, however, are subject to valid existing rights perfected prior to the date the area was withdrawn. Some of these areas are known to be encumbered by unpatented mining claims. As a consequence, even though the areas are withdrawn, they could be subjected to the possible effects of mining. Before any mining is permitted in these areas, an evaluation will be made to determine if valid rights exist.

2) Production Potential

A mineral resource overview has been prepared to assess the present and future potential for the development of locatable mineral resources on the Forest. Maps depicting the areas of potential are available in the FEIS. In summary, the overview indicates that the Forest has potentially significant occurrences of copper, gold, molybdenum, silver, lead, zinc, tungsten, iron, chromium, nickel, mercury, and manganese, in approximate decreasing order of importance. The Forest also contains potentially commercial deposits of bentonite, feldspar, limestone and garnet. The other nonmetallic minerals of a locatable nature reported either have no apparent commercial potential, or are of interest only to collectors.

Depending upon the results of on-going exploration and development activities and on changes in the volatile nature of the mineral's supply/demand situation, the level of activity could change drastically over a short period of time.

At the present time, it appears that exploration and development activities in the area are concentrating on precious metals, and of these gold appears to be of most interest. The interest can be attributed to two things: (1) anticipation of higher gold prices; and (2) major improvements made in recovery technology. The areas most likely to be explored for gold within the next few years include the Horse Lake Mountain and Blewett areas on the Leavenworth Ranger District, the Swauk Creek area on the Cle Elum Ranger District, the Entiat Ridge area near the Lake Wenatchee Ranger District and the Red Top Mountain and south Mt. Stuart batholith areas of the Cle Elum Ranger District.

Silver-based metal mineral resources on the Wenatchee National Forest, with one exception, appear to be low grade and of small volume relative to grade. These probably will require supply constraints and significant price increases in order for development to take place. The exception is the Chelan-Sawtooth area where evidence is emerging which indicates the occurrence of a medium to high grade silver-lead-zinc deposit.

Nonmetallic mineral resources of possibly a locatable nature include feldspar, garnet, limestone, silica and bentonite deposits. Of these, the Wenatchee Ridge feldspar deposits appear to have the most potential for future development. Actual development of these commodities will depend more upon processing technology, commodity research, and the establishment of markets, than on exploration and development activities.

3) Demand

At present, the Forest processes approximately 100 notices of intent to operate and plans of operation per year. In addition to this, it responds to more than 500 public inquiries concerning mineral resources and conducts numerous administrative reviews and compliance checks. Considering Bureau of Mines predictions of a 1.0 to 2.2 percent increase in demand for mineral commodities, it is assumed that this level of activity will continue or increase slightly over the next 10 years. Should the availability of non-domestic sources of metallics (especially gold, silver, copper and chromium) change, then the demand for the Forest's sources of these commodities would increase significantly. Because of these trends and the vulnerability of non-domestic sources, locatable mineral related activities (claim staking and maintenance, exploration, development, panning, sluicing, suction dredging and rock-hounding) is expected to remain at a relatively high level throughout the next 10 years. Should exploration activities being conducted on the Forest prove positive and mineralization similar to that at the Cannon Mine near Wenatchee be

identified on the Forest, or should the availability of non-domestic sources of metallics change, then larger-scale locatable mineral activity accompanied by production will increase significantly.

b. Leasable Minerals

1) Current Management Program

Leasable minerals are those mineral commodities which may be acquired under the Mineral Leasing Act of 1920, as amended. On the public lands of the Wenatchee National Forest, they include coal, oil, gas and geothermal resources. On "acquired" lands, however, all minerals except salables are leasable. These minerals are subject to exploration and development under leases, permits, or licenses granted by the Secretary of Interior. Leasing is presently administered by the BLM in cooperation with the Forest Service. The following table summarizes Forest Service mineral leasing responsibilities for the public land it administers:

**TABLE II-25
MINERAL DISPOSAL AND ACTIVITY RESPONSIBILITIES**

Commodity	Public Domain - Administered by the FS	Acquired Lands - Administered by the FS	Preliminary Prospecting Permits
Oil and Gas	BLM requests FS consent for leasing	BLM requests FS consent to lease and FS concur	FS has authority to issue a permit
Coal	BLM requests FS consent to lease and permit to operate	BLM requests FS consent to lease and permit to operate	FS permit specifically prohibited
Hardrock Minerals	Locatable--Nondiscretionary	BLM requests FS consent to issue a prospecting permit, to lease and to operate	FS has authority to issue a permit
Geothermal	BLM requests FS consent to lease and to operate	BLM requests FS consent to lease and to operate	FS has authority to issue a permit

As with the locatable minerals, wilderness areas and certain other areas are withdrawn from mineral leasing. On those lands which are not withdrawn from leasing, recommendations concerning their availability for leasing, and concerning the environmental protective measures which should be attached to a lease, will be based on the environmental conditions and the management objectives adopted for the land upon which an application has been received.

2) Production Potential

Even though there are no leasable mineral commodities presently being produced on the Forest, revenue produced from mineral leasing during FY-85 was \$215,676. This represents rental returns only. Should production begin, royalties would increase this revenue substantially.

Portions of the Forest have been classified by the Bureau of Land Management (previously USGS and Mineral Management Service) as being prospectively valuable for oil, gas, coal and geothermal resources. Those areas classified prospectively valuable for leasable minerals are considered to have at least a "moderate" mineral potential for future production until exploration proves otherwise.

As a result of BLM's leasable mineral classification efforts, 212,044 acres on the Forest are considered prospectively valuable for oil and gas resources, 599,902 acres are classified prospectively valuable for geothermal resources, and 540,350 acres are classified prospectively valuable for coal resources. Of the area classified prospectively valuable for oil and gas, 73,565 acres have been identified as an "area of critical mineral potential" for its oil and gas resource potential.

Recent exploration drilling conducted on lands lying to the east of the Forest has encountered very good shows of gas, though apparently not in commercial quantities. Even though oil and gas resources are not presently known to exist on the Forest in commercial quantities, based upon the results of off-forest exploration it is assumed that the Forest does have potential for the occurrence of petroleum resources.

As with oil and gas, geothermal resources are not known to occur on the Forest in commercial quantities. However, parts of the west one-third of the Forest have been classified "prospectively valuable" for the resource. Pending the acquisition of additional subsurface data, it presently appears that the highest potential for geothermal resources is limited to the high Cascades in the southern part of the Forest.

MINERALS

A large portion of the Forest has been classified "prospectively valuable" for coal resources, while a smaller area near Cle Elum has been classified as a "coal resource area". Even though these deposits contain 41,000,000 tons of "measured", "indicated" and "inferred" resources classified as high-volatile "A" bituminous coal, it does not appear that their development is likely in the near term.

3) Demand

None of the existing or terminated leases have been producers, but they do indicate an interest in the area's potential. It appears that the leasing cycle, however, is in a downturn mode and without some important discovery, the area leased is expected to remain below 200,000 acres at least for the foreseeable future. In addition to the oil and gas leases, a total of 24 geothermal lease applications covering 56,350 acres were filed for in the White Pass and Cougar Lakes area. Since most of the applications lie within areas designated as wilderness under the Washington State Wilderness Act of 1984, they have either been rejected or withdrawn. There are presently no coal leases or pending lease applications, and it appears unlikely that there will be any interest in leasing the coal on the Forest over the next 10 years.

Barring any significant discoveries off-Forest, oil and gas activity on the Forest over the short-term is expected to remain relatively low and will be dominated by leasing actions and exploration activities. Based upon available data, it appears that geothermal resource related activities conducted on the Forest in the short-term will be dominated by geophysical investigations and possibly exploration. Relatively small-scale direct use development is possible, but large scale development is not anticipated. In response to changing energy demands, considerable attention has recently been focused on the production of methane from unmined and unmineable coal seams in Washington. Since this type of development will depend on detailed investigations of the resource and on future technological improvements in recovery methods, it is unlikely that such development will occur within the next ten years.

c. Salable Minerals

1) Current Management Program

Salable minerals are common varieties of sand, stone, gravel, pumice, pumicite, cinders and clay. In general, these minerals are of widespread occurrence and are of relatively low unit value. They are generally used for construction materials and for road building purposes, however, they may be used for decorative purposes as well. These minerals are sold, rather than being leased or located, and their disposal is totally at the discretion of the Forest Service (see regulations in 36 CFR part 228). Management of operations on permit areas is similar to the management of leasable mineral activities.

2) Production Potential

The Forest maintains a detailed inventory of rock sources. This inventory, which identifies the location, type, quality and quantity of rock available at each source, is available at Ranger District Offices. The potential for developing this mineral resource is highly controlled by the deposit's geographic location relative to population centers or areas of use (road construction, timber harvesting activities, bridge and dam construction, etc.), and on the availability of funding for construction projects. There appears to be an adequate supply of crushable rock sources throughout the Forest to accommodate any anticipated demand. However, good quality sand and gravel is in short supply.

3) Demand

The total production of sand and gravel and stone during the period from 1973 to 1984 was approximately 3.8 million tons, which has an estimated value of 8 to 10 million dollars. The annual average production since 1973 has been about 320,000 tons. However, demand has lessened the last few years in response to the reduction in road construction activities. The Forest presently issues 50 to 100 permits annually to the public for the removal of 6,000 to 25,000 tons of cinders, pumice, rock, sand and gravel. The dominant market for mineral materials, however, is in

support of the Forest's timber management program and for public works projects. To support these activities, an additional 100,000 to 300,000 tons of various common variety mineral resources are removed annually. Since demand for these mineral commodities is highly influenced by the location of the resource, the health of the timber industry and its associated timber harvesting activities, and on the availability of capital for construction projects, it is difficult to predict what the future demand will be. Based upon available data, however, the demand has lessened over the last 2 years and it appears that the demand on a Forest-wide basis will not increase significantly over the next 10 years. On a local basis, if specific projects are approved and funded, the demand could increase appreciably.

d. Recreational Minerals

1) Current Management Direction

Those collectible minerals of a "locatable" nature are removed from valid mining claims under the authority of the Mining Law of 1872, whereas removal of more than nominal amounts of the common variety minerals requires that a permit be issued. In either case, if significant surface resource disturbance might be caused, a notice of intent or plan of operation must be filed and approved. If suction dredging or stream alteration is involved, hydraulic project approval must be obtained from the State. Since managing this type of activity in the past has not been a significant problem and it is not anticipated to become a problem in the future, current management practices will continue. There does appear to be some interest in the opportunity to allocate lands specifically for rockhounding and mineral collecting purposes. Other than for those areas identified in the Alpine Lakes Management plan (Redtop Mountain area and portions of Peshastin, Negro and Ruby Creeks), no areas will be withdrawn and specifically managed for this type of recreational activity.

2) Production Potential

Even though there are about twenty types of minerals recreationally collected on the Forest, placer gold, agate, quartz crystals, garnet, talc or soapstone, olivine, rhyolite, pyrite, rhodenite and actinolite appear to be the main targets of collectors. The areas experiencing the most activity of this nature appear to be the Red Top, Big Creek, Kachess Lake, White River, Cle Elum Lake, Peshastin, Negro, Ruby and Swauk Creeks, Wenatchee Ridge, Manastash Creek and Deep Creek areas. However, there is also interest in other localized areas. The potential for the mineral resources of this type to accommodate the recreation demand for them has not been assessed.

3) Demand

It is anticipated that the recreational mineral related activities will continue at or increase slightly above the present level. Any large increases in the price of gold, however, would be accompanied by significant increases in panning, sluicing, and suction dredging activities of a recreational nature.

13. LAND STATUS

Background

About 293,199 acres, or 12 percent of the land within the Forest boundary, is not National Forest land. Many of these lands are in a "checkerboard" ownership pattern, affecting about 25 percent of the Forest. Most of this checkerboard ownership is in the center of the Forest in the vicinity of Stevens (U.S. 2) and Snoqualmie (I-90) Passes and along the east side of the Forest. Much of the intermingled private land is managed for timber production by large corporate landowners. Almost all of it is within the roaded portion of the Forest and only a minor amount is within wilderness or other unroaded areas. This pattern is evident on the Forest map.

LAND STATUS

Other agencies also manage land within the Forest. The Washington State Department of Natural Resources manages more than 30 square miles of land scattered throughout the northeast part of the Forest (primarily Sections 16 and 36). The Washington Department of Game manages about 10 square miles of land of the affected sections within the Forest boundaries, and the Washington State Parks Commission manages about one square mile of land--Lake Wenatchee State Park.

In addition, there are many existing withdrawals from mineral entry for power sites, reclamation administration, and recreation. The Bonneville Power Administration has several major energy transmission corridors on the Forest which are managed under Memorandums of Understanding. This need of other agencies (Federal, State, and local) to occupy and use National Forest land with travel and utility corridors requires considerable management attention and interagency coordination.

To improve resource management and reduce the costs of National Forest administration, the Forest continues to be engaged in several land exchanges with owners of intermingled lands.

Although many rights-of-way have been acquired through private land, there is a continuing program for the acquisition of trail and road rights-of-way in order to ensure public access to National Forest lands.

Occasionally it is in the public interest to purchase private lands. This was the case with the private lands within the Alpine Lakes Intended Wilderness and key recreation lands within the Lake Chelan and Lake Wenatchee recreation areas. In the last few years, especially on Lake Chelan, emphasis has shifted from purchase to acquiring recreation or scenic easements. An Icicle Creek composite is being developed. Acquisitions in these composites will continue under this Plan.

a. Land Adjustments

The Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA) targets for land purchase and exchange for the Forest are about 3,000 acres per year from 1985 through 1990. Under current national direction, little or no purchase can occur outside the Congressionally directed Alpine Lakes acquisitions. Land exchange activities will largely be limited to work under existing agreements with Burlington Northern Inc., the State of Washington Department of Natural Resources, and Longview Fibre Co. A long-term land ownership adjustment program involving these three major landowners could potentially involve about 120,000 acres of private land and a similar acreage of National Forest land. Other small parcels would be acquired by exchange or purchase on a need and opportunity basis.

In order to better accomplish resource management objectives and improve efficiency, the Forest has ongoing land exchange programs with the State of Washington Department of Natural Resources (DNR) and Burlington Northern Timberlands Inc. The agreement with the DNR identifies an eventual adjustment involving about 20,000 acres in each ownership. The program with Burlington Northern Timberland Inc. proposes the study of about 83,000 acres of Burlington Northern lands and about 53,000 acres of National Forest land for possible exchange. The Forest is also working on two exchanges totaling about 23,000 acres of private land and 17,000 acres of National Forest land, with Longview Fibre Company.

In "checkerboard" ownership areas, industrial forest management practices result in much faster harvest of old-growth timber on private land. This rate of cutting and the related roading substantially affect roading and harvest on the public lands because of the cumulative effects of these activities on soil, water quality, and wildlife. It also limits the opportunity to manage the public lands for unroaded uses.

The subdivision and development of private lands within and adjacent to the Forest is accelerating. Current examples are: (1) The Murray Pacific lands in Chelan County above Fish Lake and in the Chiwaukum, Hatchery and Icicle Creek areas; and (2) the Pack River Management Co. lands in

the bottom of the Icicle Creek drainage. Such changes impact public land management in several ways. These include fire protection, access, sanitation (water quality) and trespass. Private land development also increases the recreation use of the Forest in these areas and increases the demand for the use of National Forest lands for water systems, sanitation systems, utilities and access. There are also demands to preserve the natural environment in proximity to summer homes or year-round residences. This creates pressure to restrict management options on activities such as timber harvesting and road, trail and campground construction.

In order to allow maximum utilization and adequate protection of public resources, the ownership pattern requires either: (1) a large, long-term landline survey program; (2) large-scale land ownership adjustments to eliminate the mixed ownership; or (3) a combination of the two.

b. Special Land Uses and Utility Corridors

The Forest provides lands for a wide variety of special uses by private individuals and public agencies. Such uses are authorized by special use permits, mining laws, and withdrawal authority of other agencies. The most common are those covered by special use permits. Examples of permitted uses are recreation residences, pastures, power or telephone lines, fences, irrigation ditches, water transmission pipelines, roads, dams, emergency airstrips, electronic sites, ski areas, and resorts.

There are about 1,469 special uses on the Forest. Seven hundred thirty-nine of these occupying 2,486 acres, are for recreational purposes. Another 730 occupy about 20,752 acres of National Forest land, and are termed non-recreational special uses. These uses produced \$402,505 in fees in fiscal year 1988. The number of permits and acres under permit change as some permits terminate and new uses are added. However, the trend is for more and more uses as time goes on. The uses have the effect of limiting the options in these areas for other uses including public recreation, timber harvest, livestock grazing, and facility construction.

Special uses are periodically inspected to insure compliance with conditions of the permit and to evaluate the appropriateness of continuing such use. Most permittees are charged fees for the privilege to use National Forest lands.

Utility corridors are managed under Cooperative Agreements and Memorandums of Understanding. The Forest maintains about 200 of these documents to administer various uses. Currently, power transmission lines are the major use of utility corridors on the Forest with three major energy utility corridors crossing the Forest through Stevens, Snoqualmie and Stampede Passes. The rights-of-way for these lines are from 100 feet to 1,400 feet in width and they occupy about 1,420 acres of National Forest land. The Western Regional Corridor Study for the State of Washington has also identified one potential corridor. It would cross the crest of the Cascade Range in the area between Tacoma Pass and Pyramid Peak. The corridor would then run southeasterly toward the Hanford and Tri-Cities area. In the short term, additional power transmission needs can be met by increasing the capabilities of existing utility corridors.

A moderate to strong demand can be expected for all special uses in the future. This is based on the number of applications currently received for non-recreation special uses. The right-of-way acquisition, grants of right-of-way and road construction cost sharing are expected to continue at about the current level. As the road system develops over time, these programs should be phased out, except for cost sharing of road reconstruction and maintenance. The need for these activities will also be reduced to the extent that land exchanges with the major landowners within the Forest consolidate ownerships, eliminating the need for cost sharing, granting and acquiring right-of-way, and surveying and marking property boundaries.

c. Hydroelectric Energy Development

There are no major hydroelectric power projects within the Forest. There are several projects adjacent to the Forest on the Columbia River. One project, Chelan Falls, relies on water storage in Lake Chelan. Generation of electric power

results in a 17 foot annual fluctuation in the level of Lake Chelan, and affects National Forest land management adjacent to the shoreline.

There are two minor projects of long standing on the Forest. One is the Holden project on Copper Creek at Holden Village. The other is the Trinity project on Phelps Creek on the Lake Wenatchee Ranger District. Both of these projects have existed for more than 30 years and serve small, isolated camp/organization sites.

Over the last five years, the Forest has had an average of about 25 small hydroelectric proposals pending. Most of these never go beyond the preliminary permit and feasibility study stage. Many are "repeats" where one proponent surrenders a preliminary permit for a proposal and another party applies for a preliminary permit for the same site.

Three proposals have reached the stage of applying for licenses to construct and operate small hydroelectric projects. They are the Tieton, Clear Lake and Railroad Creek projects. The Tieton and Clear Lake proposals involve "retrofitting" existing irrigation storage dams to produce power. The Railroad Creek proposal would be a totally new project to provide power for the Holden Village organization site.

14. ROADS

a. Current Management Program

Currently 33 percent of the total Forest and 53 percent of the non-wilderness acres are considered roaded. In the roaded areas, there are approximately 3.75 miles of road for each square mile of land. Within these sections, the roads actually occupy about 4 percent of the land area.

In 1988 there were an estimated 5,110 miles of Forest Service roads on the Forest. About 18 percent of this total are classified as arterial and collector roads. Forest arterials and collectors access large or popular land areas and usually connect with State and County roads to form an integrated network of primary and secondary travel routes. The system is 98 percent complete,

however, some is in need of reconstruction. About 82 percent of the total system are local roads. These facilities are usually intended to provide access for a specific resource utilization or protection activity, such as a timber sale, a recreation site, or a firebreak. These roads are normally shorter and serve smaller areas of land. Resource service rather than travel efficiency is emphasized in their location, design and operation. The analysis of the management situation indicates that the local road system is about 76 percent complete. Ground slopes influence the choice of logging systems and the logging system determines the local road location and density. Typical permanent road densities (miles/Section) necessary to harvest timber in unroaded areas on the Forest are 3.12 miles for gentle slopes, 2.64 miles for moderate slopes, and 1.10 miles for steep slopes. Approximately 0.4 mile of additional road construction or reconstruction per million board feet is necessary for subsequent entries.

1) Bridges

The analysis of the current management situation has identified approximately 35 bridges that will need replacement or reconstruction in the next 10-15 years. These are log bridges that are greater than 15 years old, treated timber bridges greater than 25 years old, steel or concrete bridges greater than 35 years old, bridges whose capacity is significantly (75 percent) less than current legal loads, or bridges where inspection reports indicate significant damage, corrosion, or decay.

2) Forest Road Management

Road management objectives for all existing roads have been identified and stored in the Transportation Information System (TIS). A system has been developed to identify the resource objectives and the appropriate standard and management of all proposed roads. The existing and proposed levels of service for the arterial and collector roads are found in Chapter IV.

15. FIRE

a. Current Management Program

Fire has played an important developmental role in many of the ecosystems found on the Wenatchee National Forest. As our management of these ecosystems has intensified so has our desire to manage the frequency and amount of change caused by fire. We now separate the fire management program into two different facets. One is the suppression of wildfire, and the second is the application of prescribed fire.

1) Wildfire Suppression

The wildfire protection facet of the Fire Management Program consists of four activities. They are; Presuppression, Prevention, Detection, and Suppression.

Presuppression activities include all the preparation necessary to initiate efficient fire suppression efforts. In recent years this has included the rapid expansion of Interagency Agreements in an attempt to utilize all local fire suppression resources efficiently. The Wenatchee National Forest maintains agreements with many Federal, State, and Local entities which facilitate the management of the fire program on an inter-agency basis.

The current management program allocates approximately two million dollars per year to ensure the readiness of equipment and personnel for fire suppression efforts. Included in this allocation is funding for the following fire suppression resources which are funded by the Forest Service Regional Office and "hosted" on the Wenatchee National Forest (Two Air Tankers, One Helicopter with Rappel crew, One Lead Plane, One Hotshot Crew, and One Regional Fire Cache). The training and development of the fire management personnel is also included in this funding as is the acquisition and maintenance of the fire suppression equipment.

Detection

Detection of wildfires most commonly occurs by the public. About 80% of all wildfire reports come from the general public. The remaining 20% of the fire reports come from a combination of Lookouts, Aerial Detection Systems, and employees of the agencies involved in fire suppression. Increased Interagency cooperation has improved the efficiency of our fire detection efforts in recent years. This has resulted in a reduced number of lookouts being staffed and less hours being flown by aircraft for observation purposes.

Prevention

The Forest has developed and maintained an aggressive fire prevention program to reduce the number of human caused wildfires. A variety of communication and public media systems are used to inform the public of fire prevention activities, current conditions, and fire prevention needs. Throughout the past ten years the emphasis of fire prevention has evolved from efforts to provide individual personal contacts to increased use of public communication systems. Organized and timely use of the media reaches more people in a structured format and is less costly than organizing to accomplish individual contacts.

In addition, the Forest participates with the Washington State Department of Natural Resources and several other agencies, in the Industrial Fire Prevention Program which regulates the industrial activities which can occur on National Forest Lands.

Even with the fire prevention efforts outlined in the preceding paragraphs the Wenatchee National Forest has a history which shows that this area is subject to frequent wildfires some of which become very large. The following two tables show the relationship of fire occurrence and the incidence of large fires on the forest. Table II-26 shows the annual lightning and human caused fire occurrence and acres burned from 1957 through 1985. Table II-27 shows the number and size of the large fires that have occurred from 1960 to 1985 and their acreage.

Suppression

The current direction for the management of wildfires was implemented on the Wenatchee National Forest in May of 1984. It directs the fire manager to implement a fire suppression strategy which is efficient and includes the following considerations; land values of the area, resource values in the area, public and private property, existing and predicted weather and burning conditions, fuel volume and condition, terrain factors, and the availability of suppression resources. It should be emphasized that all wildfires that occur on the Wenatchee National Forest have been managed utilizing a cost-effective suppression strategy and this will continue after the implementation of this plan.

Fire suppression is accomplished utilizing a variety of equipment. Aircraft is utilized when effective. Tractors and other heavy equipment are used when the terrain and management practices allow. But, the primary suppression efforts are made by individuals utilizing handtools to construct fireline and mopup. The techniques for doing this job have not changed radically during the past 50 years.

2) Prescribed Fire

The second facet of the Fire Management Program is the use of prescribed fire. Prescribed fire may be used for a variety of land management objectives which range from site preparation for reforestation activities to browse improvement for wildlife habitat. Each prescribed fire has specific objectives and can only occur given predefined environmental conditions. If the objectives are not being obtained or the environmental conditions are not correct the fire is managed as a wildfire and suppressed.

With the implementation of the Alpine Lakes Wilderness Management Plan the use of natural ignitions (lightning) to initiate prescribed fires became possible. At this point the experience we have gained in managing natural prescribed fire within this wilderness is limited. With the implementation of this plan and after appropriate planning and documentation has occurred, the opportunity to expand the use of natural ignitions exists.

The prescribed fire program on the Wenatchee National Forest currently varies from approximately 4,000 to 8,000 acres per year. These acres are treated utilizing a variety of techniques ranging from broadcast burning to the burning of piled forest debris. The techniques being employed have evolved rapidly in the past ten years with the development of computer based models which have helped predict the amount of fuel consumed, the intensity of the fire, and the dispersion of the resultant smoke. These tools, combined with a well trained workforce have resulted in professional application of prescribed fire.

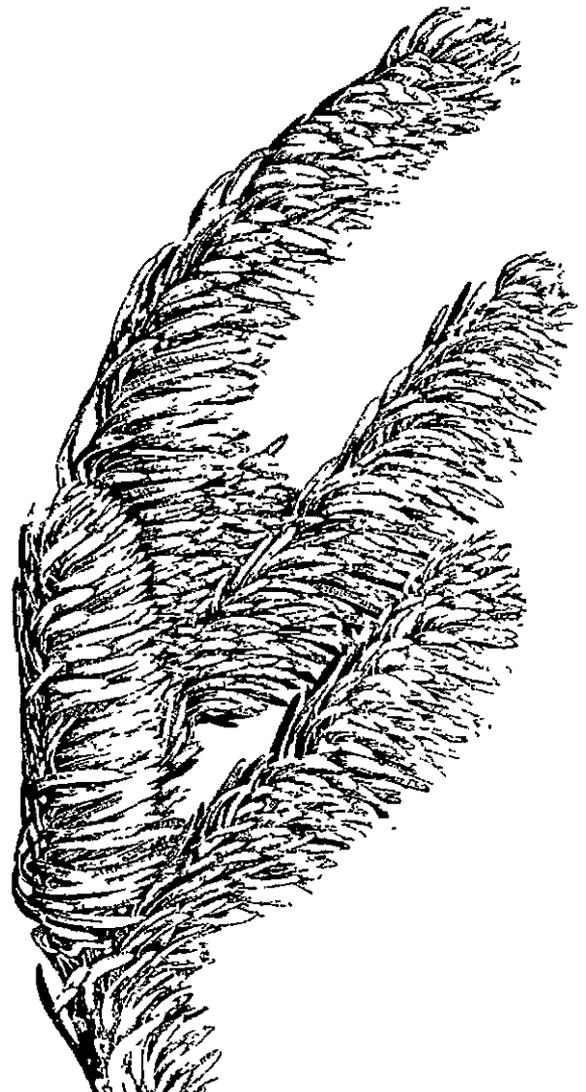

TABLE II-26

ANNUAL FIRE OCCURRENCES BY ACRES AND CAUSE
1957 - 1985

Year	Lightning Caused (Fires)	Human Caused (Fires)	TOTAL (Fires)	Lightning Caused (Acres)	Human Caused (Acres)	TOTAL (Acres)
1957	21	60	81	Unknown		92
1958	111	51	162	Unknown		10,927
1959	7	50	57	Unknown		206
1960	13	111	124	---	1,084	1,084
1961	189	83	272	---	5,773	5,773
1962	63	74	137	388	294	682
1963	132	91	223	185	3,645	3,830
1964	13	67	80	2	2,280	2,280
1965	128	100	223	7	205	212
1966	37	102	139	1,520	124	1,644
1967	8	91	99	---	676	676
1968	18	69	87	10	28,484	28,494

16. SOCIAL/ECONOMIC

a. Current Management Program

1. Social

Communities within and adjacent to the Forest are concerned about a balance of natural and human related resource activities. Many of the residents of the communities in the area of the Forest derive their livelihood from forest related activities and many participate in a wide variety of forest recreational activities. These residents have a keen interest in the management of the Wenatchee National Forest.

The recreational activities and environmental amenities offered by the Forest are important components of life in the small rural recreational and residential communities located in and around the Forest. Examples include the Lake Wenatchee area, Leavenworth, and Chelan. Because the economic base of these communities depends on tourism, they are affected by changes in the pattern of recreational opportunities on the Forest. They are also affected by changes in environmental quality, and benefit from opportunities for free and easy access to forest resources and products. Firewood, fish, game, and water are among forest resources important to local communities. The preservation of these Forest qualities is of great importance to these communities.

Rural communities whose economic life is tied to logging, sawmills, and related transportation and construction are also affected by changes in the supply of timber from the Forest. The productive use of resources and products is an important value of forest management.

In addition to the residents of the three-county (Chelan, Kittitas, and Yakima) area, Forest management affects out-of-area recreationists who live in the metropolitan areas of Washington. These people typically have concern for recreational and visual quality, wilderness, road access, and hunting opportunities. Their ties to the Forest are principally through the recreational activities they engage in.

2. Population

The three counties have an area of 9,503 square miles and a population of almost 250,000 people. Yakima County is the most densely populated (40 people per square mile) while Kittitas County has the least population density (11 people per square mile). Most people live in the larger towns and cities scattered along the east side of the mountains, especially Wenatchee, East Wenatchee, Ellensburg, and Yakima. About 90 percent of the people in the three counties live in the agricultural valleys. Residents in the eastside communities are affected by the Forest through availability of recreation, the payments to County governments from Forest receipts, production of market goods such as lumber and beef, (Table II-28), and other amenities such as enjoyment of the visual character of the Forest.

TABLE II-28
SOURCE OF COUNTY REVENUES - 1984
(In Dollars)

County	1984 Property Tax Revenue Levies	Wenatchee N.F.	25 Percent Funds Given to Counties Based on National Forest Receipts ^{1/}		
			Mt. Baker ^{2/} Snoqualmie N.F.	Gifford Pinchot N.F.	Total National Forest Payments to Counties
Chelan	17,390,291	1,337,183			1,337,183
Kittitas	6,938,570	334,059	176,479		510,538
Yakima	43,938,061		1,490,029	255,616	1,745,645
Totals	68,266,922	1,671,242	1,666,508	255,616	3,593,366

^{1/} 25 percent funds are based on proclaimed National Forest boundaries. This is for Fiscal Year 1984 (October 1983-September 1984)

^{2/} Administered by the Wenatchee National Forest, but the 25 percent funds are based on Mt. Baker-Snoqualmie National Forest receipts.

3. Employment

Major employment comes from city, county, State and Federal agencies, trade and service, lumber and wood products manufacturing, and agriculture, especially apples, soft fruits, cattle, hops, potatoes and wheat.

Table II-29 depicts some of the major employment categories considered in Washington State and the three-County area with the numbers of employees in each.

4. Human and Community Resources

The Forest is part of a nation-wide program of human and community development, which has as its primary goal helping people and communities to help themselves. The program includes activities that provide work and learning experiences for youth, adult employment, training opportunities, and technical assistance to individuals and communities.

The Forest has been actively engaged in a wide variety of manpower and youth training programs. The Youth Conservation Corps (YCC) Program provides employees between the ages of 15 and 18 with employment and experience in a natural resources environment. The Senior Community Service Employment Program (SCSEP) provides part-time employment for senior citizens whose incomes are within poverty levels. Other programs the Forest has been active in include: The Comprehensive Employment Training Act (CETA), College Work Study, and the Young Adult Conservation Corps (YACC) Programs.

The Volunteers in the National Forest Program has become increasingly important as funding levels decrease for some of the above programs. This program, authorized in 1972, has been used extensively to accomplish necessary resource activities such as campground host work, trail construction, wilderness patrol, and many other jobs. Many volunteers are highly qualified individuals who are retired or young people unable to find jobs in their profession, trade, or area of interest because of current economic conditions and the lack of employment opportunities. Volunteer programs are expected to increase.

The Forest has the ability to utilize Human Resource Programs to accomplish many Forest projects. For example, there is a continuing need to improve buildings, campgrounds, and trails, to improve young timber stands through thinning and pruning; and to accomplish soil and water improvement programs. Although there is a backlog of projects that can be accomplished, the funding for these programs varies from year to year because of National budget priorities. Because of this, these programs are not always available when needed.

In 1984, the Forest had the following enrollment in these programs:

	Person Years
YCC	2.11
Campground Hosts	1.85
Volunteers	20.72
SCSEP	10.32
TOTAL	35.00

The outlook is for these programs to continue at about this same level.

Various programs have been implemented for minorities and women to benefit both the Forest and the individuals. This effort is reflected in Forest Service hiring, supervisory, and contracting procedures.

5. American Indian Treaty Rights

Certain rights and privileges are afforded members of the Yakima Indian Nation and the Wenatchi Indian members of the Colville Confederated Tribes under the Treaty of 1855. The treaties provide that on the ceded lands, the Indians will continue to have the rights such as the taking of fish in streams running through and bordering the Reservations and at all other usual and accustomed stations in common with the citizens of the United States; and the privilege of hunting, gathering roots and berries, and pasturing stock on unclaimed lands. These rights will be considered through management of appropriate resources such as fish, wildlife and riparian areas. The entire Wenatchee National Forest is within the area ceded by the Yakima Indian Treaty.

C. INFORMATION NEEDS

This subsection addresses the information, inventory, or research needs that have been identified by the Forest Supervisor in the EIS.

The Information Needed by Resource or Use include:

Recreation

1. Geographic Information System layers for roads and trails to aid in further refinement of Recreation Opportunity Spectrum (ROS) mapping and capacity coefficient accuracy. Data is needed by the first plan revision.
2. Follow-up on research done on Dispersed Recreation activity preferences in the Taneum-Manashtash area. This is needed by plan revision to aid in discussing any changes in demand for different dispersed recreation activities.
3. A uniform method for determining and applying demand for various forms of recreation. This will be tied to the ROS system. This is needed for the next round of planning to aid in improving estimated recreation demand.
4. Forest and site/area specific information is needed to have more localized data concerning Off Road Vehicle impacts on wildlife and their habitats.
5. Further research is needed to develop guidelines for use in determining an appropriate mix of Outfitted versus Non-outfitted visitors to wilderness and in establishing party sizes compatible with various wilderness ecosystems. This will be tied to the Wilderness Recreation Opportunity Spectrum system. This information should be developed during the plan implementation period.
6. An inventory of campsites in wilderness is needed to aid in planning and monitoring the impacts of recreation use.

Cultural Resources

1. Completion of the cultural resource overview of the Forests historic resources. Overview should be completed by 1990.
2. Completion of the cultural resource inventory, including data pertaining to site content, condition, location, and range of types existing on the Forest. Inventory of all manipulated acres is needed by the first plan revision. Remaining Forest acres should be completed by the fifth decade.
3. Refine the cultural resource field sampling survey strategy through comparison of known site distributions to the predictive model developed for the Forest (areas of High, Moderate, and Low probability for the occurrence of cultural resources). Revision should be completed by 1990, and every five years thereafter.
4. Establish the major cultural themes that are represented on the Forest, and identify the range of cultural properties that is associated with each. This will form the foundation for decisions concerning their significance and treatment. Should be completed by the first plan revision.
5. Identify the specific areas of archaeological research needed to close current information gaps, and to aid in evaluation and management. Identify the classes of prehistoric sites that exist, the known or estimated frequency of occurrence, and their relationship to the full range of Forest environments. Should be completed by first plan revision.
6. Determine those sites for which American Indian religious concerns may exist in addition to the standard National Register considerations. This may take precedence over any research values inherent in the property, and may prompt a different type of management prescription than would otherwise apply. To the extent the relevant American Indian groups are willing to share this information, it should be completed by the first plan revision.

INFORMATION NEEDS

7. Tie in the Forest cultural resource data base with the State-wide historic preservation plan and determine the specific relationship of the Forest properties to the regional research design. This will affect decisions regarding significance and long-term management of cultural resources. Should be completed by the first plan revision.

Wildlife

The Forest Service manages habitat but is also concerned that habitat is occupied even though the Washington Department of Wildlife is responsible for the animals.

The information available on indicator, threatened, endangered and sensitive species needs to be upgraded to provide management with reliable information and assessment.

The upgrade of information is planned to be accomplished by:

1. Development of Species Management Guides. Species Management Guides will gather known information, identify inventories needed, research needs, models and costs for doing each. Each indicator, threatened, endangered or sensitive species will have one or more Species Management Guides developed in the next 10 years.

The "Forest Plan Monitoring Worksheets" identify the general areas of information needs in the "Remarks" section.

Fisheries

Many general interactions of fish and other resources are known from research that has been conducted around the world. Much of the research on cold water species, both anadromous and resident, is probably valid on the Wenatchee National Forest. However, complete inventories of the Forest have never been done so the research is difficult to apply. Many of the numbers and projections in this Forest Plan are therefore best estimated with only limited inventories. Furthermore, some basic questions about the Forest, cannot be answered reliably. For instance, some of the answers to the following questions are not known:

1. Are Forest-wide riparian standards valid? Will they provide conditions necessary to maintain or improve fish habitat and are the standards valid for streams on the Wenatchee National Forest?

2. Where are the fish-bearing streams located?

3. What habitat factors are limiting fish production?

4. What are the effects of clearcutting large percentages of drainages on fish? Especially, cumulative effects in intermingled ownerships?

5. How much are management activities contributing to the degradation of aquatic habitat, if at all, and how can we better predict the effects of management activities on fish habitat?

6. What is the smolt habitat capability for anadromous fish on Forest Service managed streams?

7. What is the potential to produce resident fish?

8. What lakes have fish, what species, and how many?

9. Where are the opportunities for habitat improvement?

10. How many culverts on fish streams are not adequate for fish passage and what are the effects?

11. What is the status, distribution and habitat preference for bull trout? What is limiting production?

The answers to these questions are needed to adequately monitor the effects of Forest Plan implementation and for the first plan revision. Methodology will have to be developed to address the 10 questions. Much of the information necessary will become available upon implementation of the stream inventory program, and the monitoring plan.

Threatened, Endangered and Sensitive Species

Threatened, Endangered and Sensitive (T, E and S) plants and animals by their nature are uncommon and often inhabit unique or unusual habitats. Consequently, it is not unusual that little is known about Threatened, Endangered or Sensitive species and it is difficult to apply knowledge from other closely related species.

Plants and Animals

Inventories of T, E and S species and their habitat are necessary to provide adequate management guidelines and evaluations. Actual population locations or potential habitat should be mapped on high quality maps of at least 1:24000 scale. Although sightings are currently sent to the Washington Natural Heritage Program or Washington Department of Wildlife and project areas are being inventoried, there currently is no systematic process for mapping all populations and appropriate habitat. A plan is required to complete this mapping. As a geographic information system looms as a valuable management tool in the near future, these maps would serve as a data source to develop an important data layer.

Many unanswered questions about T, E and S species will require research to answer. These questions concern (among other things): habitat requirements; population biology; genetic variability; reproductive biology; effects of fire; population trends; extent of range; effects of natural succession; and effects of management practices. It is important to know more about these things so that the future needs of T, E and S species can be predicted and planned for.

Species Management Guides or Recovery Plans are required for all T, E and S species and will be used to direct management activities thereby reducing the possibility that a species of concern is negatively impacted.

Plants

Once a vegetation classification has been completed for the Wenatchee there is a need to determine the plant associations that represent typical habitat for the T, E and S species. Once

done this will allow a much more accurate prediction of the kind of habitat required by any given rare plant or animal and be an aid in project planning and execution.

It is impossible to inventory all National Forest Lands in sufficient detail to locate all populations of rare plants. Consequently, there is a need to train all types of field personnel to be able to identify T, E and S species. In this way the days spent on the ground by all types of people as they do their normal jobs can also serve to help locate rare plants.

Vegetation: Research Natural Areas

There is a constant need for suitable areas to fill needed cells in the Research Natural Area (RNA) system. This is especially true of low elevation forest and forest-margin sites. Completion of a plant association classification of the Forest is a real need and will help to delineate the types of potential natural plant communities present. As cell needs are updated using this soon to be completed plant association guide there will likely be a number of additional RNA's proposed for the Wenatchee. The Research Natural Area "Yellow Book" should also be updated to reflect the new information provided by the completion of a number of plant association classifications in the Pacific Northwest.

Location of potential sites for Research Natural Areas should be encouraged. The Forest will consult with the regional RNA scientist on potential sites and receive proposals for suitable areas from the RNA committee. After proposal, an establishment record is required as part of the establishment process for an RNA. This record includes a description of the proposed area, its features, the objective for management and the management direction. A survey of the area will be necessary to gather the information required to complete this report.

Biological diversity

The issue of ecosystem or biological diversity is a complex one that touches many attributes of forest planning. Biological diversity is difficult to quantify, especially on a National Forest of over 2 million acres.

Some of the topics related to diversity that require additional information include: old growth, sensitive species, and forest fragmentation; among others. Consequently, more information is needed on how to define and measure diversity, including a model to provide quantitative diversity index. How much diversity is "normal". How much old growth is required to maintain diversity and meet the needs of a concerned public. What definition(s) of old growth will be used; then, how much old growth is there and where is it? How much fragmentation is normal and how does artificially caused fragmentation relate to natural conditions. Where are the sensitive plant species on the Forest and what is the status of their populations? All of the above questions will require inventory and/or research to answer.

Vegetation: Trees

More specific data is needed on the expected results from management activities on the various vegetative types. The area ecologist is expected to complete an area guide covering the Forest types in 1989. Of particular concern is the productivity of upper elevation conifer stands and potential results of intensive management.

A second major concern is the accuracy of yield predictions for areas managed with emphasis on other resources including scenery, old-growth and mature dependent species, big game, and riparian protection.

Vegetation: Forage

Forage production information is needed for transitory forage types, both inside and outside of existing allotments. More Forest specific information is needed on production by decades following silvicultural activities or fire, to better predict production potential through the planning horizon.

A more definitive method is needed to calculate Forest-wide forage production. A method using satellite imagery (Land Sat) keyed to Forest specific production is recommended.

Water

The information needs for the water resource are closely tied to those described in the sections for fish habitat and soils. A primary need exists to develop a stream inventory data base in conjunction with fisheries. A revision of the Forest's Watershed Improvement Needs Inventory is needed to improve the focus of this capital investment program.

A need exists to develop/validate models used to analyze the cumulative effects of timber harvest and road construction on water quantity, quality and stream channel stability.

Research is needed on rain-on-snow events for the east slope of the Cascades. The results of similar studies conducted in Western Oregon may not fit the conditions that are found on this Forest.

Research is needed to develop a better understanding of sediment routing (transport and storage) over a range of stream types in differing geology. This information is needed to improve our abilities to predict the amount and effect of fine sediment deposition on fish habitat.

A need exists to develop improved inventory and monitoring techniques used for water and related resources. New methods will be needed to facilitate the shift from traditional water quality sampling toward evaluation of stream channel and watershed condition.

Soil

The Forest has identified the following as new or continuing research needs for the soil resource.

1. Natural erosion/sedimentation rates from forested landtypes over a variety of parent materials, soil textural classes, and slopes.
2. Erosion and sedimentation rates from road construction, timber harvest, mining, fire, and grazing over a range of landtypes.

3. Short and long term effectiveness of erosion control measures applied to a variety of practices and soil types.

4. Continued research into logging, machine piling, and fire effects on long term soil productivity (especially in regards to site prep., compaction, nutrient loss, etc.).

5. Effects of soil compaction on soil erosion and site productivity over a variety of slopes and soil types.

6. Cumulative effects studies to develop and/or evaluate existing models with the objective being to come up with a predictive model that really reflects cumulative effects and can be validated.

7. Studies that will determine long term soil productivity and show trends over time for at least the major soil types on the Forest.

Mineral Resources

The mineral resource data may need to be updated according to newly implemented standards for mineral input to land management planning (draft *Procedural Guide for Integration of Energy and Mineral Resources in Forest LMP Process*, dated December, 1985). Accomplishment of the following will assist in meeting the objectives:

1. All active mineral operations should be inventoried and identified (including name of site, location, commodity, annual production in appropriate units).

2. Identify information inadequacies (eg., commodity and annual production).

3. Rate management areas according to their activity favorability. This should be by locatable, leasable, and salable mineral resources.

4. Rate the management areas according to their probability for occurrence of mineral resources.

5. Inventory outstanding and reserved mineral rights.

6. Inventory existing withdrawals.

7. Inventory acquired lands.

8. Solicit industry input, and rate management areas according to industry interest.

9. Re-analyze supply/demand forecast situation.

10. To the extent practical, determine probability of activities, their location, the level of exploration and development under the management situation, and the economic conditions necessary to trigger the activity.

11. Develop mineral cost and benefit information.

Roads

There is a need to know more about the effects of road construction and operation on the physical environment: soil, air, water.

There is a need to know more about the effects of road construction and operation on recreation use and patterns of use.

There is a need to know more about the effects of road construction and operation on fish and wildlife.

Fire Management

1. More information is needed on the effects of prescribed burning on timber yields.

2. More information is needed on the effects of prescribed fire on soil erosion, soil productivity and water yields on the Entiat, Wenatchee, Chiwawa, Icicle, Yakima, Naches, and Tieton River drainages.

3. There is a need to develop best predictive methods for smoke dispersal - Eastside Cascades.

CHAPTER III

RESPONSE TO ISSUES, CONCERNS AND OPPORTUNITIES

A. INTRODUCTION

A major step in the development of this plan was the identification of issues and concerns related to management of the Wenatchee National Forest. These issues and concerns were identified through citizen participation including public meetings, interagency coordination, personal contacts with individuals and groups, and the comments to the DEIS and proposed Forest Plan. In this chapter, these issues are summarized and a brief description of their disposition in this plan is provided. The reader is encouraged to read Appendices A and K of the Environmental Impact Statement (EIS) for a more detailed description of the issues and concerns, and for how comments to the DEIS were handled. Chapter I of the EIS describes how the issues evolved since the release of the DEIS. The issues and concerns are listed as follows:

Recreation Opportunities and Use Conflicts
Management of Areas That Are Presently Undeveloped
Wild, Scenic, and Recreational Rivers
Water Quality and Quantity
Wildlife and Fish Habitats
Old Growth Forests
Management of the Scenic Resources
Timber Production
Range Management
Management of Cultural Resources
Cumulative Effects of Management Activities
Social Economics

B. RESPONSE

1. RECREATION OPPORTUNITIES AND USE CONFLICTS

Discussion of the issue

The Forest receives about 5 million visitor days of use a year. It is one of the most heavily visited National Forests in the United States. Use is continuing to increase, and conflicts between recreational user groups (off-road vehicles, hikers, horses, snowmobilers, cross-country skiers, etc.) are becoming more evident. For instance, there are issues about noise pollution from off-road vehicles in narrow canyons, such as Devil's Gulch, and in areas like the Teanaway, and Lake Clara. In addition, some recreation activities can cause resource damage because of the level, type, or location of use. There is also a demand to separate different types of recreation use by areas, and to separate uses within some areas such as hikers and off-road vehicles. Regulation of commercial use is included in the issue.

Recreational use at certain times of the year in such key wildlife habitat areas as Swakane Canyon and Oak Creek may disrupt wildlife. Timber harvest access roads can increase roaded dispersed recreation opportunities but reduce primitive and semi-primitive recreational opportunities. The potential effect of road development on trails is an issue.

There are opportunities to reduce user conflicts by separating uses through land allocations. Scenic areas, unroaded dispersed recreation areas, areas for motorized or non-motorized use, and classified Wild, Scenic or Recreational rivers are all potential allocations that would separate use. It is also possible to eliminate or reduce damage or conflicts through information programs and by applying seasonal or year-long restrictions on uses of trails or areas.

The Forest has an opportunity to develop or expand recreation sites, and ski areas, such as Mission Ridge and White Pass. There is an opportunity to use project design to encourage maintenance of recreational trails when timber is harvested.

Response to the issue

There are 6,021 acres allocated to developed recreation sites including; campgrounds, picnic areas, ski areas, resorts, recreation resident tracts, boat docks, observation sites and trailheads. The plan provides for expansion of this capacity when demand exceeds the existing supply. Some 13,717 acres along the Mather Memorial Parkway are allocated to developed and roaded recreation use without management activities such as scheduled timber harvests.

Approximately 933,700 acres of dispersed recreation opportunity in a roaded setting will be provided. The setting for a part of this recreation opportunity is modified through timber harvest and other management activities which have emphasis in a portion of the roaded allocations. Some roads not needed for management activities will be closed which will help diversify recreational opportunities. Within the roaded setting important travel routes have reduced timber harvests levels in order to retain scenic values on 83,635 acres allocated to retention visual quality and 174,880 acres allocated to partial retention visual quality.

There are 96,355 acres allocated for unroaded, motorized use, while 116,092 acres outside of wilderness (841,034 in wilderness) are allocated to unroaded, nonmotorized use. In addition there are 70,512 acres in classified special interest areas which permits motorized use to the extent it is

compatible with the management intent. There will be some trails, either existing or to be constructed, within the unroaded, motorized allocations which will be managed for nonmotorized use.

The total miles of trails will not be decreased as a result of management activities. Trails that are affected by roads will be reconstructed.

A preliminary administrative recommendation will be made on 230 miles of rivers and streams contained in some 73,600 acres to be considered by Congress for inclusion in the Wild and Scenic Rivers system.

Recreation opportunities to meet demand, reduce conflicts, and minimize resource damage will be accomplished in this plan by allocating the following amounts to recreation emphasis management: developed recreation - 0.3 percent of the total Forest; dispersed, roaded recreation - 45 percent; dispersed, unroaded, motorized recreation - 5 percent; dispersed, unroaded, non-motorized recreation - 5 percent; special interest sites - 6 percent, and wilderness - 39 percent.

The Plan's allocations result in the Forest's settings being 45 percent roaded, 16 percent unroaded, and 39 percent wilderness.

2. MANAGEMENT OF AREAS THAT ARE PRESENTLY UNDEVELOPED

Discussion of the issue

A total of 556,272 acres of the Forest outside of designated wilderness are presently roadless.

Some of these areas could continue to be managed in a roadless condition, while others could be roaded to provide easier access for the enjoyment of scenic and recreational values as well as for the development of other resources. Areas which can provide unroaded types of recreation, both motorized and non-motorized, are becoming more scarce. People are concerned about how much of these areas should be managed for timber as opposed to management for roadless recreation and wildlife habitat.

Others would like to see some of these areas roaded to provide scenic drives or campgrounds. There is also a concern about how quickly these areas should be entered and the effect roading and management activities have on soils, water quality, old-growth forests, and wildlife and plant species dependent on old-growth forests.

There is an opportunity to provide for a variety of uses in the presently undeveloped areas. These could include unroaded recreation, roaded recreation, commodity production, and special area classification. The selected use would determine which lands would be roaded and how soon roading might occur. There are opportunities to help meet national and regional targets for timber and mineral production.

There is also an opportunity to use roadless areas to help meet management goals or targets for research natural areas, endangered, threatened and sensitive plant and wildlife habitat, and old-growth stands for dependent species such as the spotted owl. These land allocations could be made in wilderness or unroaded recreation areas rather than in timber management areas whenever possible. There are opportunities to maintain the future suitability of roadless areas as potential wilderness additions.

Response to the issue

In order to reach the most appropriate mix of resource management for these non-wilderness undeveloped areas, this plan will allocate 313,677 acres or 56 percent of the current inventoried roadless areas to continued unroaded status. In addition there are 79,840 acres, dispersed throughout the roaded areas, which are dedicated to spotted owls and other old growth/mature dependant wildlife species, where timber harvest will not occur. The remaining unroaded areas will be entered for various resource management activities at a gradual rate.

3. WILD, SCENIC AND RECREATIONAL RIVERS

Discussion of the issue

This issue was considered a part of issue Number 1. (recreation opportunities and use conflicts) in the DEIS and Proposed Plan, but due to public response to the DEIS, the Wild and Scenic Rivers section was greatly expanded in the 1988 Supplement to the DEIS.

In the DEIS three rivers on the Nationwide Rivers Inventory were proposed for further study in the preferred alternative. The Entiat River and two tributaries were analyzed but not recommended for proposed study in the preferred alternative. An eligibility evaluation was made on twenty rivers and streams in the 1988 Supplement to the DEIS and an additional thirteen streams were evaluated after responses from the public were received. A total of thirty-three rivers and streams on the Forest have been evaluated for eligibility. Ten rivers and streams have been determined to be eligible.

Responses to the Draft and the Supplement indicated that some people believe that all of the rivers and many streams on the Forest should be included in a preliminary administrative recommendation to Congress for consideration under the Wild And Scenic Rivers Act. Other people are strongly opposed to the recommendation of some or all rivers and streams (or certain segments), particularly rivers or segments of rivers with private lands within the river corridor. Some are also concerned with the level of classification proposed for those river segments outside wilderness.

There is an opportunity to provide for a variety of uses on eligible rivers and streams on the Forest through preliminary administrative recommendations to Congress for consideration under the Wild and Scenic Rivers Act.

Response to the issue

Of the thirty-three rivers and streams analyzed, nine of the ten eligible rivers and streams will be recommended to Congress for consideration under the Wild and Scenic Rivers Act. The nine streams total 230 miles within 73,600 acres (60,126 acres of National Forest). Of the 230 miles, 82.5 miles are proposed for Wild River classification, 29 miles are proposed for Scenic classification and the remaining 118.5 miles for Recreational River classification.

4. WATER QUALITY AND QUANTITY

Discussion of the issue

The Forest currently produces more than 4.5 million acre feet of water runoff annually. A number of cities and towns near the Forest use water coming from National Forest lands for domestic purposes. This use will increase as communities grow, and the demand for sediment-free irrigation water will increase as new lands are cultivated. At the same time, increases in most uses (recreation, timber management, roading) will make it more difficult to maintain water quality and meet the demands for increased water quantity. The maintenance of enough clean, cool water for human use and fish and wildlife needs is a fundamental concern. An issue here, also, is protection of water quality and anadromous fish habitat. It is also important to assure that Forest responsibilities are met in regard to the Yakima Indian Treaty fishing rights.

Riparian zone (streamside) management provides the opportunity to enhance wildlife, recreation, scenic values, and fish habitat by providing hiding cover and thermal protection. There is also the opportunity to minimize ground disturbance while at the same time protecting water quality and soil productivity. There are also opportunities to improve the condition of some of the watersheds on the Forest.

Response to the issue

The 55 percent of the Forest allocated to wilderness and to unroaded areas are located in the higher precipitation zones and will not be subject to vegetative manipulation.

Within the roaded portion there are 47,361 acres allocated to riparian and aquatic habitat protection zone management. An additional 428,795 acres in the roaded portion have reduced management activities in allocations for Scenic and Recreational Rivers, Experimental Forest, Scenery, and Old Growth. Water quality will be maintained or enhanced by the plan adhering to the Forest Standards and Guidelines and Best Management Practices. Water quantity will be increased by 15,500 acre feet due to acres allocated to lands subject to vegetative manipulation through timber harvest.

5. WILDLIFE AND FISH

Discussion of the issue

The Wenatchee National Forest sustains a wide variety of fish and wildlife species because of its variety of habitats. Activities that affect habitat (trees, grass, shrubs, soil, and water) can have a direct influence on fish and wildlife.

This issue includes the maintenance and management of essential habitats and maintenance or enhancement of animal diversity. The issue also involves identification and protection of threatened and endangered species and recognition of wildlife needs for old-growth forest stands. Management activities that affect fish and wildlife habitat are timber harvest, recreation, livestock grazing, road management, and fire management.

Small hydroelectric projects and irrigation impoundments may alter the quantity and quality of available fish habitat. This issue includes maintaining quality of available fish habitat. It also includes maintaining habitat quality for anadromous fish, although the existing habitats are now generally under-utilized. The presumption is that, as a result of the Fish and Wildlife Program of the

Pacific Northwest Electric Power Planning and Conservation Act of 1980, anadromous fish levels should increase to fully utilize the existing habitat.

There are opportunities to manage key habitat specifically for wildlife (e.g., winter ranges, key summer range, old-growth, fawning and calving areas) and for fish (e.g., riparian protection zones) through management area designations. There are opportunities to work more closely with the Washington State Departments of Game and Fisheries, the U.S. Fish and Wildlife Service, and the Yakima Indian Nation, to improve the management of fish and wildlife habitat on the Forest.

Response to the issue

The 55 percent of the Forest allocated to wilderness and to unroaded areas will be retained in a natural habitat condition, including old-growth habitat.

In areas outside of wilderness and roadless areas there are 128,855 acres allocated to old-growth and mature habitat, 47,361 acres allocated to riparian and aquatic protection zone management and 118,742 acres allocated to big game management all of which have key wildlife and/or fish habitat objectives. An additional 299,940 acres in roaded areas have reduced management activities in allocations for Scenic and Recreational Rivers, Experimental Forest, and Scenery. Wildlife and fish habitat will be maintained or enhanced by the plan adhering to the Forest Standards and Guidelines, habitat improvement projects and Best Management Practices.

This plan is highly responsive to the need to maintain and improve resident and anadromous fish habitat.

6. OLD-GROWTH FORESTS

Discussion of the issue

This issue was considered a part of issue Number 5. (wildlife and fish) in the DEIS and Proposed Plan, but due to public response to the DEIS and the growing national concern for old-growth, this issue has been handled as a separate planning problem in the FEIS.

This issue includes the maintenance and management of essential habitats, viewing old-growth, and maintenance or enhancement of vegetative diversity. The issue also involves identification and protection of threatened and endangered species and recognition of wildlife needs for old-growth forest stands. Management activities that affect old-growth are timber harvest and the amount of timber that can be harvested, road management, some types of recreation and fire management.

Some people believe that all existing old-growth on the Forest should be preserved for, biological diversity, dependent wildlife species, scenery or aesthetic values, and/or because they feel that no more old-growth forest will remain in a few years. Others believe that old-growth, both existing and potential, within designated wilderness is more than enough to meet all future needs.

Response to the issue

The 55 percent of the Forest allocated to wilderness and to unroaded areas will be retained in a natural habitat condition, including old-growth habitat. In areas outside of wilderness and roadless areas there are 128,855 acres allocated to old-growth and mature habitat.

Of the 105,900 acres of existing old-growth on allocations available for timber harvest, 85,800 acres are on suitable timber lands. There are 11,500 acres expected to be harvested in the first decade, and an additional 11,600 acres in the second decade. Of the 318,800 acres of existing old-growth, over 307,300 acres (96%) would remain at the end of this ten year period.

7. MANAGEMENT OF SCENERY

Discussion of the issue

The Forest is well known for its sweeping vistas, variety in topography, diverse ecotypes, life forms, and overall natural appearing environment. About 13 percent of the recreational use on the Forest is driving for pleasure and viewing scenery. As more demands are placed on the Forest for timber and other uses, it becomes more difficult to maintain a pleasant forest atmosphere and a natural appearance. Timber management can complement the scenic resource, and visual management can complement wildlife habitat and recreation management. The issue involves the degree of protection scenic values should be given and the cost and impacts of visual management on other Forest activities, such as a reduction in the annual timber harvest and the cost of implementing visual management practices.

There are opportunities to complement other management goals through the creative management of Forest scenery. There are also opportunities to maintain and enhance the scenic quality of the major travel corridors. Finally, there is an opportunity to rehabilitate previously modified landscapes for improved scenic values.

Response to the issue

The natural appearance of some landscapes will be moderately reduced under the plan. The management direction needed to maintain the key or unique visual resources are contained in this plan.

The land allocations will result in 39 percent of the forest appearing natural, 39 percent of the forest appearing natural to slightly modified and 22 percent appearing modified. Acres by visual quality objective are:

Preservation -	
843,281 acres	39 percent of the Forest.
Retention -	
521,800 acres	24 percent of the Forest.
Partial Retention -	
332,927 acres	15 percent of the Forest.
Modification -	
147,828 acres	7 percent of the Forest.
Maximum Modification -	
318,344 acres	15 percent of the Forest.

8. TIMBER MANAGEMENT

Discussion of the issue

Timber management is a major activity on the Forest. How much timber should be produced in the future and where it should be produced is one of the principal planning problems addressed by this plan. Increasing demands for other uses and implementation of management direction for other resources will reduce future harvests below historic levels. This reduction results from a combination of incorporation of management requirements, increased visual resource management, allocation of areas to roadless management, and additions to the wilderness allocation. For example, the 1984 addition of 340,795 acres of land to wilderness also reduced the acreage available for timber management by about 51,500 acres.

This issue involves other issues such as wildlife habitat, recreation opportunities, road densities, visual and cultural resource management, water quality, and range management. Timber management activities may be in competition with some of these issues such as the need for old-growth forest for dependent wildlife and the need for unroaded recreation areas. This plan responds to these issues through allocation to old-growth and unroaded recreation.

There are opportunities to allocate the most suitable, productive timber lands, where management activities are most cost effective (such as Meadow Creek and the Little Naches) to long-term, high-intensity timber production. There are also opportunities to benefit other resources at little or no extra cost. These include improvement of big-game cover/forage relationships, development of temporary forage for wildlife and livestock, and selective timber removal to improve the visual condition of travel corridors, open views of surrounding landscapes, and promote increased vegetative diversity. These opportunities are responded to through various allocations and management direction contained on Chapter IV.

Another opportunity is the replacement of stands where the heaviest timber mortality and disease is occurring. Per acre timber productivity is expected to increase by 12 percent in the next 50 years as a result of harvesting these stands and planting genetically superior seedlings, as directed by the guidelines in this Plan.

There is a sizable existing and potential supply of cull timber material and small round wood which present marketing opportunities. The main source is from cull material not utilized for sawlogs, and undersized wood from logging residue, precommercial thinning, disease and insect mortality, and stagnated stands. This material has a wide variety of present and potential uses for specialty building materials, energy production, pulp and fiber products, and home firewood.

Response to the issue

This plan schedules harvest on 576,074 acres which includes 73 percent of the tentatively suitable timber production land. Of the 576,074 acres, 303,897 are in prescriptions which will approximate full yield and 272,177 acres will yield from 50-90% of full yield. From these acres, timber harvests are planned averaging 26.1 million cubic feet per year (146.0 MM board feet per year) during the next five decades.

This Plan will provide the best balance between timber management and other resources.

9. RANGE MANAGEMENT

Discussion of the issue

Livestock grazing presently takes place on the Forest through grazing permits issued to 36 local livestock owners. Permitted livestock use has declined in recent years although it is still a significant activity on the Forest. As other uses have increased, potential conflicts with domestic grazing have become more apparent. At the same time, managers are concerned about future development and management of grazing resources for use by livestock.

Livestock grazing has the potential to conflict with recreation, water quality, wildlife, fish, and timber. When livestock use the same meadows, streams, and trails that recreationists use, conflicts may result. Unmanaged livestock use of streamside (riparian) areas may cause compaction of soils and reduced water quality due to stream-bank disturbance. There may be competition between livestock and big game for available forage.

Livestock grazing can complement other activities including recreation, wildlife, and timber. Sheep grazing can retard brush growth in meadows and along trails. Wildlife forage areas can be maintained or improved through intensive grazing systems. Timber management activities such as clearcuts, partial cuts, and thinnings may provide temporary forage areas. Grazing use can also reduce brush and grass competition which will enhance tree establishment and growth.

Response to the issue

The management direction needed to improve vegetative conditions and reduce conflicts is provided for in this Plan. Land allocations with the corresponding standards and guidelines reduces conflict and/or competition between livestock and other resources or uses. This Plan provides for the continuation of permitted livestock use within existing allotments only. There are 406,872 acres of tentatively suitable grazing land within existing allotments and approximately 203,400 acres will be suitable for use in any given

decade. Permitted livestock grazing will be occur on approximately 9 percent of the total Forest acreage.

The level of livestock grazing will increase 1,000 Animal Unit Months in the first decade and will remain constant at approximately 24,000 Animal Unit Months through the duration of this plan.

10. CULTURAL RESOURCE MANAGEMENT

Discussion of the issue

There is an ongoing program to identify and evaluate the historic and prehistoric cultural resources which exist on National Forest lands. To date, over 800 cultural resource sites (archeological sites, historic structures, etc.) have been reported within or adjacent to the Wenatchee National Forest. These sites represent a broad cross-section of uses, spanning a period of several thousand years. Decisions about how best to manage these sites relate to such issues as historic significance; local community interest; American Indian concerns; accessibility, recreational, research, or interpretive values, and compatibility with other management activities.

As land-modifying activities and public use increase within the Forest, so does the possibility of loss or degradation of the cultural resources. The degree of potential impact will depend upon the location and extent of land alteration, the nature of the site, and the concentration of public use. In these instances, appropriate mitigation methods may be necessary to reduce or eliminate the undesirable effects or to recover the historic values of the properties prior to their alteration. The most desirable management prescriptions, however, are those which effectively protect the site in place, are economically prudent, and are compatible with other resource management needs and uses. A central concern is to provide a balance between these other uses and the protection of cultural sites so as to provide adequately for their preservation.

Several opportunities exist in the management of cultural resources. Timber harvesting can complement the cultural resource program by providing opportunities for the identification of previously unknown cultural properties. Field reconnaissance accelerates in proportion to the number of acres scheduled for harvesting. In addition, in heavily vegetated environments, removal of the understory and organic duff layer may provide the only means of locating archaeological sites (Lake Wenatchee, for instance).

Recreational use increases opportunities for interaction between the public and cultural resources. Interpretive programs through which the Forest visitor can both enjoy and appreciate the cultural resources can be planned and developed with community involvement. One such area is the Stevens Pass Historic District. An active effort to solicit public opinion well in advance of the development of a management direction for an area or property could help to define the level of anticipated demand for its use and preservation.

There is also an opportunity, in those instances where on-site preservation is not possible, to carry out data recovery which could contribute locally and regionally to significant research questions and, in some cases, could build a deeper awareness of the contributions of American Indians to the public heritage.

Response to the issue

Cultural and Historic resources will be protected in place on the 55 percent of the Forest allocated to wilderness and to unroaded areas. For the remaining 45 percent of the Forest the Forest-wide Standards and Guidelines should offer protection from the moderate to high level of impact on cultural resources from other land uses and management activities.

This Plan provides for a variety of management options and opportunities for enhancement of cultural resources. The number of sites identified will be high. Good accessibility of managed sites to the public will also be provided.

11. CUMULATIVE EFFECTS OF MANAGEMENT ACTIVITIES

a. Water Quality and Quantity Cumulative Effects

Cumulative effects of timber harvest activities on watersheds (on water quality, quantity, and runoff timing and on fish habitat) in intermingled ownerships is a major concern. Unfortunately, activities, especially the rate and method of timber harvest, of neighboring land owners are unknown. Indications are that most commercial timber on the intermingled lands will be harvested within the next 10-15 years. Under the Forest's selected management scheme, the Upper Yakima River, Swauk/Naneum Creeks, Taneum/Manastash Creeks, and Little Naches River watersheds are the most likely to experience impacts from cumulative effects. On a case-by-case basis, these watersheds will need to be analyzed for possible impacts. Management activities on National Forest lands may need adjustment as a result of detailed sub-drainage analysis.

Overall, water quality should be maintained with adherence to the Plan's Standard and Guidelines and the Region's Best Management Practices. Water quantity will be increased by 15,500 acre feet, primarily due to 576,074 acres of suitable timber lands subject to vegetative manipulation through timber harvest.

b. Intermingled Ownership and Scenery Cumulative Effects

Travel corridors that have a significant amount of private land could have cumulative effects upon the scenic quality. Areas where timber harvest on private land could affect scenic quality are: Lower Entiat Valley, Icicle Valley, Blewett Pass area, Lower Ingalls Creek, Shaser Mountain area, Stevens Pass (Highway 2), Cle Elum Valley, Kachess Basin, Cooper Lake Basin, Taneum-Manastash--Quartz Mountain, upper end of South Fork Tieton, Naches Pass north along the crest to Snoqualmie Pass, and Quartz Mountain north along the ridge to Blowout Mountain. Large blocks of these "checkerboard" landscapes will not likely be kept in a natural appearing condition. These areas will definitely have increased

alteration of the landscape with the areas being seen from the travel routes, from recreation roads and trails, and high vista points within the viewshed.

12. SOCIAL ECONOMIC

a. Forest Influence Zone

The Forest Influence Zone is the geographic area where the majority of forest resources such as recreation, range, timber, water, and wildlife are first used and where public concern is concentrated. Chelan, Kittitas, and Yakima Counties comprise the Forest Influence Zone for this analysis.

b. Population

The 1983 population of the Forest Influence Zone was 248,400 persons. This is almost 6 percent of the State's population. About one-half of the population lives in rural settings; the other half lives in urban settings. This area has an older age distribution than the State average. Chelan and Kittitas counties have proportionately lower minority populations than the State. Yakima County has a proportionately higher minority population due to the Yakima Indian Nation and a large Mexican-American population. The rate of population growth in the three-county area has been slower than State-wide over the last 40 years.

c. Economy

Economic activities in Chelan, Kittitas, and Yakima Counties are closely tied to the activities of the Wenatchee National Forest. A large proportion of the residents of this area rely on the commodity and amenity resources of the Forest. Economic activities affecting local individuals include logging, sawmill operations, commercial livestock operations, tourism, and various recreational pursuits. Residents of the study area participate in nearby forest recreation activities such as hunting, fishing, hiking, and a range of winter sports, thereby generating demand for recreation-related goods and services.

The economy in the area east of the Wenatchee National Forest rests heavily upon agricultural production. Yakima County is the State's leading agricultural county with a diversified farm base. Its principal products include apples and soft fruit, cattle, hops, potatoes, and wheat. The economy of Chelan County depends primarily upon deciduous orchard crops, with apples being the predominant crop. Kittitas is primarily an agricultural county producing crops and livestock.

The central Washington area is very important to the State's economy because of its agricultural base. These counties support 36 percent of the State's agricultural employment with Yakima County alone supporting 27 percent (ESD 1984).

The agricultural sector will remain the dominant force in the economy of central Washington. The strong demand for agricultural products abroad, as well as the anticipated strength of domestic demand will, if anything, increase the importance of agriculture in central Washington. This trend should continue at least through 1990 and may become even more pronounced in the future.

The lumber and wood products industry in the Forest Influence Zone represented 3.7 percent of the State's employment for that industry in 1983 (ESD 1984). Yakima County has the largest lumber and wood products work force among the Central Washington counties, with 1,048 workers in 1983. This represented 17 percent of manufacturing employment in the county, and 2 percent of total employment. Chelan County's lumber and wood products industry employed 293 workers in 1983, for respective manufacturing and total county employment shares of 14 percent and 1.5 percent. The lumber and wood products work force of 72 in Kittitas County was much smaller in absolute terms, but still accounted for 17 percent of all manufacturing jobs in the county and 1.1 percent of total employment.

The forest products sector of the economy will likely decrease in importance in the future. The extent of this decline, however, will be influenced by several factors. Most notably, the reduction in timber available from private land may cause an overall slump in timber production in the region, and could very likely contribute to a reduction in

capacity or closure of local mills. This reduction could lead to further pressure for increasing the harvest from National Forest System lands. This pressure should become particularly intense in the 1990's, or earlier, should housing demand rebound substantially from its low levels in the early 1980's.

Visitors to the Wenatchee National Forest have an impact on the local economy because of expenditures they make for goods and services at establishments nearby. Data on the number of retail trade establishments are available from the U.S. Census Bureau for States and counties. The variables selected as indicators of local economic dependency on recreational use include the following: 1) hotels, motels, and recreational vehicle parks; and 2) eating and drinking establishments. While these components of the service industry receive a significant amount of business from nontourists, trends in these two service industries reflect growth or decline in the tourist industry.

A particularly active sector of the regional economy will be the tourism sector. An increase in summer and winter recreation activities, particularly along the major travel routes, is expected in the 1990's. The increase in the cost of energy will likely focus the greatest recreational demand near the transportation corridors leading from the Puget Sound area population centers. Recreational demand will be greatest in those areas close to the Everett-Seattle-Tacoma metropolitan area.

The importance of the agricultural sector in the Forest Influence Zone is recognized through protection of water quality. The Wenatchee National Forest will provide riparian zone (streamside) management practices to protect this important resource.

The Plan provides for a harvest of 146 MM board feet per year. This recognizes the importance of the forest industry while providing for and protecting other resources.

Additional areas are allocated to roadless areas, wildlife habitat, and recreation in recognition of the changing demands of society on the Wenatchee National Forest.

CHAPTER IV

FOREST MANAGEMENT DIRECTION

A. INTRODUCTION

This chapter presents the management goals, objectives, and standards and guidelines that constitute direction for resource management covered by the Plan. Included in this chapter are:

1. Forest Management Goals

- Multiple use and other goals established in the planning process to develop the Plan. All goals are written within the context of the land's capability to provide resources.

2. Desired Future Condition of the Forest

- What the Forest should look like at the end of 10 years, and at the end of 50 years if the management direction is implemented.

3. Forest Management Objectives

- The level of goods and services which are anticipated as the Plan, with projected budgets, is fully implemented. This display is followed by a narrative summary of resource outputs and schedules.

4. Forest-wide Standards and Guidelines

- These establish the bounds or constraints within which all practices will be carried out in achieving the objectives of this Plan.

5. Management Prescriptions

- These contain a goal, a description, and standards and guidelines by Resource Element for each management area. The standards and guidelines shown will meet management Goals and Objectives; higher ones may be achieved.

B. FOREST MANAGEMENT GOALS

Forest Management goals are statements describing a desired condition to be achieved sometime in the future. They are expressed in general terms and are timeless in that they have no specific date by which they are meant to be completed. The goals for the Wenatchee National Forest by resource are:

Recreation

Provide a well balanced array of recreation opportunities across the breadth of the recreation opportunity spectrum in accordance with resource capability, public demands and expectations for outdoor recreation.

Provide a diverse system of safe, well-maintained trails for the enjoyment of all users.

Respond to new opportunities to develop partnerships and joint ventures with other agencies and the private sector to magnify our abilities to meet expanding public demand for outdoor recreation.

Provide an information program to assist the public in understanding management of various resources and to assist them in their search for a variety of challenging and pleasing experiences.

Provide for the identification, protection, interpretation, and management of cultural resources so as to preserve their historical, cultural, archaeological, and/or architectural values for the benefit of the public.

Maintain and enhance the visual landscape character of the Forest.

Provide to the Forest visitors a variety of landscape character with visually appealing scenery.

Wild, Scenic and Recreational Rivers

Maintain recommended rivers and streams to protect their highest classification level until Congress takes action on the preliminary administrative recommendation.

Wilderness

Manage designated wilderness to perpetuate wilderness character, natural ecologic processes and to provide outdoor recreation opportunities appropriate in wilderness.

Wildlife, Fish, and Sensitive Plants

Manage critical wildlife habitat to improve the status of threatened and endangered species to a point where they no longer need protection under the Endangered Species Act of 1973.

Enhance habitat to prevent the need for listing species on the Regional Forester's sensitive species list.

Manage fish and wildlife habitats to provide for recreation opportunities for fishing, hunting, and viewing.

Protect, restore, and enhance current and long-term fish habitat capability.

Riparian Areas

Maintain and enhance riparian management areas to perpetuate their distinctive resource values to: (a) achieve and maintain habitat conditions necessary to ensure long-term natural production opportunities for desired fish species, (b) maintain water quality that meets or exceeds State AA Water Quality Standards, and (c) provide diverse wildlife habitat.

Range

Develop, protect and manage the range resource to maintain and improve vegetative conditions compatible with the management area goal.

Provide opportunities to enhance other resource values through the use of livestock to shape desired plant communities.

Timber

Provide for timber harvest to help meet local and national demand for wood products and provide an economic benefit to the American people.

Use silvicultural techniques that insure prompt and adequate regeneration of appropriate species. Optimize growth, minimize disease and insect losses, and protect or enhance long-term site productivity.

Manage vegetation to maximize total net public benefits compatible with management area objectives.

Provide information about the opportunities available through the Timber Management Program including firewood, Christmas trees, greenery, post and poles, transplants, and other specialty products.

Provide silvicultural advice and information through the Cooperative Forestry Program to local private forest landowners.

Use silvicultural techniques to provide a diversity of forest ecosystems

Water

Maintain watershed conditions and favorable streamflow to insure meeting or exceeding Federal and Washington State water quality standards.

Soil

Manage the soil resource of the Forest by using management practices that will maintain or enhance its productive properties.

Air

Prevent significant adverse effects of air pollutants and atmospheric deposition on Forest resources through compliance with the Clean Air Act and State and local regulations.

Minerals

Help meet the demand for mineral resources by *encouraging and facilitating the exploration, development, and production of mineral and energy resources, while ensuring that these activities are integrated with the use and protection of other resources.*

Lands

Strive towards a land ownership pattern that will provide for better management, protection and access to the forest.

Provide for occupancy and use of National Forest System land consistent with this forest plan and applicable laws and regulations.

Provide energy and transportation corridors to meet Regional and National needs

Facilities

Develop a transportation system that is designed and operated to standards appropriate to the planned uses, considering safety, cost of transportation, and effects upon lands and resources.

Provide for the development, betterment, and maintenance of fire and general purpose administrative facilities in support of National Forest System needs.

Maintain Forest facilities for the safety, enjoyment, and well-being of the user.

Protection

Implement an efficient fire protection program which is responsive to resource management objectives and prioritizes the protection of life, improvements, and private property.

Use prescribed fire to meet resource and land management objectives, as appropriate.

Protect Forest resources and facilities, and cooperate with State and local law enforcement agencies in the protection of visitors and protection of their property from theft, vandalism, or destruction.

Prevent or reduce losses due to insect and disease by treatment of vegetation to reduce the risk of epidemic outbreaks.

Research Natural Areas

Protect existing and nominated areas for the Research Natural Areas System to provide:

1. Baseline areas against which effects of human activities can be measured.
2. Sites for study of natural process in undisturbed ecosystems.
3. Gene pool preserves for all types of organisms, especially rare and endangered types.

Biodiversity

Maintain representatives of native and desirable non-native plant and animal species and the plant communities in which they are found. Provide for all successional stages of terrestrial, aquatic and riparian plant associations in a distribution and abundance to accomplish this goal. Maintain or enhance ecosystem function to provide for long-term integrity and productivity of biological communities.

C. DESIRED FUTURE CONDITION OF THE FOREST

It is likely to be several decades before effects of the management direction contained in this chapter are apparent throughout the Forest. The following descriptions of physical and biological settings assume that direction from this plan will remain constant through the 50 year horizon.

THE FOREST IN TEN YEARS

Recreation

There will continue to be a diverse array of recreation opportunities and settings available to the public as described in the Recreation Opportunity Spectrum Classes. Only slight changes in recreation opportunities will have occurred over 10 years time as management activities have progressed, new roads have been constructed, and vegetation managed.

Developed recreation sites in the more modified and developed end of the spectrum will have higher standards of development with more facilities for user comfort and convenience than present sites.

Most recreation sites that receive moderate to heavy recreation use will be rehabilitated or reconstructed to a high quality level to better serve the recreating public.

There will be about 1,250 People-At-One-Time (PAOT) capacity added to the developed recreation sites. This will include expansion of existing sites and construction of new sites. Additional capacity may be provided by the ski areas and other private sector development on the Forest. The number of Recreational Residences and Organization Sites will remain about constant.

Visitor use fees will be charged at the more highly developed recreation sites to help defray costs of administration and maintenance.

Management of dispersed recreation areas such as undeveloped access points on rivers and undeveloped camping sites along forest roads, will become more challenging in the next ten years. Popular

areas will continue to see increasing visitor use. Over crowding and user conflicts will become more common. Visitors in greater numbers will seek out opportunities to enjoy activities related to specialized recreation equipment. Use of boats, rafts, other water craft, motorcycles, bicycles, mountain bikes and ORV's will continue to grow. Maintenance and administration of dispersed areas will need greater management attention and put greater pressure on recreation budgets. Many visitors will experience decreased satisfaction with crowding and conflicts and will seek out new opportunities. Less popular and lightly used areas will receive increasing visitor use.

There will be approximately 388,000 acres of non-wilderness unroaded areas remaining at the end of the first decade.

Winter sports and snow related recreation activities will increase in the next ten years. Visitor use at developed Alpine skiing areas will steadily increase. Mission Ridge, White Pass and Stevens Pass Ski areas are all addressing plans for some expansion. Cross-country skiing and snowmobile use is increasing dramatically. Management activities, and recreation use will require greater coordination, particularly winter use of the Forest Road System.

Increased demand for very specific recreation pursuits will result in allocation of specific areas to specific activities in order to avoid serious user conflicts. Education of users in "light on the land" principles and stressing of user ethics will be employed.

The scenic and recreation qualities of the Mather Memorial Parkway will be retained through the implementation of a management prescription. Recreation sites and facilities in the Parkway will be given high priority for upgrading and rehabilitation.

New technology will bring new recreation equipment and activities to the Forest. Adjustments will be necessary in recreation use patterns and recreation facilities to manage new activities in coordination with existing uses. Greater coordination will be occurring to minimize user conflicts in recreation areas. New regulations will be necessary to manage new activities within land use constraints.

DESIRED FUTURE CONDITION

Greater coordination will be occurring to achieve the appropriate balance between commercial recreation activities and individual recreation use by the general public.

Use of road and trail systems by motorized recreationists will continue to grow, generating the need for more intensive transportation planning and management. Opportunities for ATV use will be considered.

Use for all types of trails will increase. Many trails will receive heavy maintenance work or reconstruction to keep up with the impact of heavy recreation use. Approximately 400 miles of new trail will be constructed in this decade. About 120 miles of this new construction will provide improved opportunities for motorized use on loop trails.

The variety in recreation settings will be retained through integrated resource project planning, resulting in special recreation settings in the Forest being protected and retained.

Vegetation management plans will be developed for all developed sites to perpetuate the desired vegetative characteristics and to provide for user safety.

Wild and Scenic Rivers

The rivers and streams recommended for classification under the Wild and Scenic Rivers Act will be protected to retain their attributes at the highest possible classification.

Wilderness

The acreage of designated Wilderness will not change under this management plan. The 841,034 acres will be managed to retain 207,920 acres in Pristine WROS class, 258,820 acres in Primitive WROS class, 117,220 acres in Semi-Primitive WROS class and 11,540 acres in Transition WROS class.

Wilderness resource values will be somewhat improved through management of recreation visitor use and increased user knowledge of proper use ethics. Although 10 years is barely sufficient time to

see substantial improvement, a general upward trend should be apparent in monitoring results.

The expected increase in visitors will result in more management actions employed to reduce use in heavily impacted areas, disperse use into areas that can accommodate more use, and more regulations to alleviate specific problems.

Wilderness user education programs will continue to be a major tool in improving the social and biological wilderness resource conditions.

Restoration and revegetation of heavily impacted areas will be on-going in areas where visitor use has resulted in loss of vegetation and unnatural or accelerated soil erosion.

The existing wilderness entry permit system may be expanded and/or new systems installed to restrict use to the appropriate carrying capacity of a specific wilderness, or portion of wilderness, where visitor use approaches or exceeds the "limits of acceptable change".

The current trail system will continue through the ten-year period. A few miles of trail may be taken off of the inventory to meet wilderness management objectives. There will also be some reconstruction of trails with short rerouting to mitigate resource impacts.

Natural occurring fire will be allowed to have a more natural effect on wilderness ecosystems. However, Wilderness fire management objectives may require that some fires that threaten other Wilderness resources or resources outside Wilderness, be suppressed.

Resource activities authorized as prior existing rights will continue under the provisions of the Wilderness Acts.

Cultural Resources

Over the next 10 years, the Forest will continue its efforts to identify, evaluate, preserve, protect, and interpret the cultural resources present within the area administered by the Forest. In addition to legislative mandates, there is recognition that, as a

non-renewable resource and a fragile, irreplaceable link with past human life, special consideration must be given to cultural properties in the course of any land management activities.

Ideally, over the next 10 years, a systematic inventory will be carried out well in advance of Forest projects, based on a professionally sound survey strategy.

As these inventories are completed, a data bank will be developed and organized so as to facilitate comparisons of individual cultural properties, provide a basis for evaluations of significance, and aid in the evaluation of cultural resource needs against other resource management goals so that informed decisions can be made. This basic data base should be available by the end of the 10 year planning period.

In the next decade, the bulk of the inventory will continue to be in support of the timber sale program. Of the 630,494 acres of suitable timberland on the Forest, it is estimated that about 450,000 acres will have cultural resource inventories completed. Approximately 25 percent of these acres will require further investigation due to known site distributions, or because of high cultural resource sensitivity. The remaining 75 percent will be cleared of the need for any further cultural resource considerations. There will continue to be substantial inventory needs on those Forest acres (such as wilderness) that are not part of the scheduled timber harvest base. Approximately 81,500 acres of these lands will have an inventory completed by the end of the decade.

The SI-2 prescription will allow for specific management for cultural values. Within these areas, management activities will be directed to the protection, preservation, and enhancement of the cultural resources present on those acres.

Cultural resource management plans will be developed over the next decade for the Salmon La Sac Guard Station, Stevens Pass Historic District, Naches Trail, American Ridge Ski Bowl, and the Leavenworth Ski Hut. See Appendix A for a full listing of these projects. These plans will specify overall management objectives, adequate measures for protection, and a program of work to accomplish these.

Small data recovery operations may be necessary over the next 10 years, particularly in the Naches watershed. Here conflicts between the management of archaeological resources in place and timber management needs are likely to be more frequent than at present. It is also possible that by the end of the decade, there will have been two major data recovery efforts on the Forest--at Lake Wenatchee and on the Naches Ranger District. The purpose of these efforts will be to recover archaeological material that is currently threatened by river action and/or vandalism. Several data recovery projects may be necessary to mitigate the effects of campground rehabilitation or construction. The data recovery projects may significantly contribute to current archaeological research by helping to refine research goals and by developing a Regional context within which to evaluate and manage other similar or associated sites.

The degree to which the above conditions are met by the end of the next decade will depend, of course, upon a sustained investment of time, expertise, and funding.

Scenery

The Wenatchee National Forest will remain well known for its outstanding mountain, valley, and lakeshore scenery. It is characterized by a natural appearing environment with a multi-level vegetative character. Large, old trees exist along most recreational use areas and viewsheds.

The Forest will continue to retain, maintain, enhance, rehabilitate, and perpetuate the scenic qualities through visual resource management practices of key areas.

The natural appearance of landscapes seen from major viewsheds and recreation sites will be changed by a variety of vegetative manipulation practices. In these areas, changes will provide an attractive, visually pleasing forest setting, emphasizing the natural appearance of the area. Vegetative management will change existing Forest stands to more open, less dense stands. It will be characterized by small openings and areas of shelterwood type treatment, leaving clumps

DESIRED FUTURE CONDITION

and individual large trees. These will be intermixed with different size trees and blended with the existing vegetation.

Within areas of intermingled ownership, nonfederal lands will have undergone timber harvest with limited consideration for the visual resource. The adjacent National Forest lands will appear altered but will blend into the landscape. Boundaries between private and federal ownership will have a diverse and contrasting form, line, color, and texture.

Most recreation sites and travel routes will retain their present scenic character. The general atmosphere along scenic travel routes, viewpoints and high recreation use areas will continue to have a feeling of a natural forest environment.

Sightseeing will be enhanced by using timber management to open up views to distant peaks, unique rock forms, unusual vegetation, or other features of interest.

Wildlife and Sensitive Plants

During the first decade, active bald eagle nest sites are expected to increase from one to five or six. Bald eagle populations are expected to increase in summer and winter as fish and waterfowl habitat improvements are completed and populations increase State-wide.

Peregrine falcon sightings are expected to increase as the population of this species increases nationally. Peregrine falcons may be re-established on the Forest in cooperation with the Washington Department of Wildlife. As these populations increase, one or two of the potential nest sites on the Forest could become occupied.

Sensitive plants and animals will be inventoried during this decade and information gathered to develop Species Management Guides. Activities that threaten these species will be reduced from the previous decade. Habitat improvements to benefit sensitive plants and animals are commonly evaluated with some being applied to enhance populations.

The number of deer and elk are expected to change because of the change in habitat from managing winter range, spring range habitat improvements, increased concern for elk and deer in timber sales, and partnership with other agencies and groups (Elk Foundation; Washington Department of Wildlife, Chelan County Public Utilities District, etc.). These increases will result in more hunting opportunities. Road closures will increase and result in increased quality hunting opportunities. Opportunities and demand for viewing of big game, small game, and non-game species will increase.

Some types of old growth habitat will increase in the first decade (Subalpine). Other old growth types are expected to decrease in acreage (ponderosa pine, Douglas-fir, grand fir). Spotted Owl habitat areas will have about a 5% reduction. Opportunities to see spotted owls and old growth will be maintained. Adequate old growth will be preserved to provide for species and community diversity of these environments.

The Forest-wide potential population of primary cavity excavators will decrease due to past practices and slow accumulation of new snags in young stands. Woodcutting of standing dead trees will be more closely regulated, timber sales will leave additional live cull or dead trees, salvage sales will give dead trees priority for wildlife, and habitat improvements for primary cavity excavators will occur. These activities will begin to change the downward trend of this habitat and reduce distribution problems that presently exist.

Mountain goat habitat will be more intensively managed during the first decade. This will either maintain or increase the number of animals. Recreational viewing sites of mountain goats will be designed to have minimum or no effects on goats. Road closures will be adopted to reduce the impacts of improved access on these species.

Old growth and mature habitat for marten and pileated woodpeckers will decrease as logging of this habitat occurs. A network has been established to maintain distribution and viable populations for these species. Even though the habitat will be decreasing, no threat to viability is anticipated.

The group of species sought for in trapping uses a wide array of habitats. These species have been abundant in the past and are expected to remain so. Some species will increase and some decrease in numbers.

There are three species of grouse on the Forest that have been found in abundance in the past. These species have experienced a general downward trend due to improved access which has resulted in increased disturbance. Habitat improvements for these species will be done to halt the downward trend.

Special habitats such as some ponds, caves, and cliffs will be inventoried and management plans developed to maintain their associated values.

Raptor nests will be protected from site disturbing activities.

Old Growth

At the end of the first planning decade it is estimated that there will be 307,300 acres of old growth on the Forest (this does not include ingrowth). Old growth acres will have declined somewhat by the end of the decade, but not as much as Table IV-2 indicates (because ingrowth of stands to an old-growth condition was not included in the table values). In wilderness and other non-harvest acres there should be more stands becoming "old growth" than those that are set back successional as a result of disturbance.

There should be adequate old growth for biological diversity, preservation of aesthetic qualities and for wildlife and plant habitat by the end of the first decade. The importance of old growth on National Forest System Lands will increase as private old growth acres are harvested.

Fisheries

Ten years from now, fish habitat within the Forest will be in at least as good condition as the current situation and should be improving. Implementation of Best Management Practices, forest-wide standards and guidelines, and the Riparian Prescription is maintaining excellent water quality and providing the stream structural components necessary for diverse, high quality aquatic habitat. While riparian areas along many Class IV channels and some seeps, springs and Class III streams have converted to early seral stages, management practices have maintained channel stability and water quality, thus protecting downstream fish habitat. Fish habitat quality has also improved due to integration of fish habitat management into other resource activities and implementation of fish habitat and watershed improvement projects.

Anadromous fish production should begin to increase during the period. The increase will be primarily tied to improvement in upstream and downstream survival, and as a result of actions initiated through the Northwest Power Planning Council, Bonneville Power Administration, mitigation settlements such as for Rock Island dam and the U.S. Bureau of Reclamation. The Forest Service will be a full partner with other state and federal fish management agencies, the Yakima Indian Nation and Confederated Tribes of Colville and private organizations in the management of fish and fish habitat.

An ongoing habitat inventory and monitoring program will be in place with initial inventories of most fish-bearing streams and many lakes on the Forest complete. This knowledge will allow Forest managers to better predict effects of management of the various resources on fish and fish habitat, quantify changes in habitat over time and minimize/avoid any negative impacts. Inventories will also be the basis for habitat rehabilitation and enhancement.

By the end of this period a habitat management plan including habitat improvement priorities should be in place for most sub-basins. These plans will be based on inventories and coordinated with other agencies, tribes and private groups. The Forest will have an active habitat and watershed improvement program.

DESIRED FUTURE CONDITION

Resident trout habitat quality should be stable to improving as is the anadromous fish habitat. Habitat maintenance and improvements combined with some improved access, especially in areas designated for roaded recreation and timber production could improve fishing opportunities. However increased fishing pressure may produce a need for special regulations to prevent over-fishing of wild stocks.

During this period, it is anticipated that a large percentage of private timberland within the National Forest boundary will be harvested. The potential effects of intensive timber management in these drainages on fish habitat are better understood and land managers are better able to identify impacts when making management decisions. Cooperative monitoring of the cumulative effects issue continues between the Forest, State and Tribal Agencies and private companies.

Riparian Areas

Ten years from now, riparian areas on the Forest will exhibit an overall improving trend. Previously degraded habitat will be recovering, while areas of good riparian habitat will be maintained. Implementation of the Forest-wide Standards and Guidelines and the Riparian Prescription will maintain excellent water quality and provide the structural components necessary for diverse, high quality riparian habitat. Riparian management objectives for projects will be established based upon site-specific conditions and on the analysis of riparian conditions within the sub-drainage. Management decision will be made in favor of riparian dependent resources where conflicts exist.

Riparian areas associated with Class I and II streams, lakes and wetlands will be characterized by vegetative conditions that emphasize advanced seral stages. Riparian areas along many Class IV channels and some seeps, springs and Class III streams will have been converted to early seral stages using management practices that maintain channel stability and water quality, thus protecting downstream fish habitat. Riparian habitat associated with Class III and IV streams, seeps and springs will provide diverse wildlife habitat conditions necessary to maintain viable wildlife populations distributed by sub-drainage.

Forest inventory and monitoring efforts during the first decade will have provided information essential to improve the management of these sensitive areas. In addition, research sponsored by Forest Service, Timber-Fish-Wildlife, and other programs will be providing information needed to validate standards and management techniques. The standards used to evaluate riparian areas will have been refined. Over most of the Forest, the interim values assigned to the riparian standards in this Plan may need to be revised or replaced by values that have been established on a sub-drainage basis.

The following statements describe the desired future condition for the major elements of Riparian Areas for details regarding the management standards applicable to each element.

Sediment - The sediment budget in each sub-drainage on the Forest is well within the range and frequency adapted to by indigenous aquatic communities.

Temperature - Summer stream temperature regimes are well-moderated with limited day to night variation. The generally cool summer water temperatures found in streams throughout the Forest are well within the tolerance levels of aquatic organisms historically found in the system.

Channel Morphology - Inherent (historic) channel forming/maintenance processes continue to operate without substantial long-term or drainage wide modifications. Relatively large pools are frequent and well distributed even during low flows. Frequent and well-distributed complexes of large wood (long and large diameter) interact over time, through a wide range of flows, to create a diversity of aquatic habitat types. A combination of these features provides a variety of functions that are important for maintaining the general health of riparian ecosystems.

Floodplain/Riparian Management Area - Floodplains and riparian management areas are fully occupied by historic plant community types. The structural and functional properties of these dynamic, multi-age communities are maintained, promoting floodplain, bank, and channel stability, resiliency to disturbance, and habitat diversity. Floodplain and wetland management promotes

the capability for detention storage of water during flood events and inherent ability to provide long-term stability of critical summer base flows.

Properly functioning floodplains also act as sites for storage of large woody debris and sediment, making this material available to maintain a relatively stable distribution, quality, and quantity of fish and wildlife habitat through time that is characteristic of the area potential. Dead/defective tree habitat, critical to the survival of many wildlife species, is maintained at least 80% of the theoretical biological potential level within riparian habitats associated with perennial streams, lakes and wetlands in sub-drainages.

Fish Passage - Access to all natural/historic fish habitat is maintained so that habitat availability is not reduced by man's activities.

Vegetation: Trees

The plan will implement a timber harvest rate that is reduced from the present. Areas harvested in the past 30 years will continue to develop through seedling, sapling, and pole stand stages. The oldest of these areas will be nearing the age when commercial thinning may begin.

Reduced numbers of large defective logs and snags will be available for fuelwood. Access into previously unroaded areas will provide fuelwood, but at longer haul distances.

Seed orchards will begin to produce genetically superior reforestation seed that will produce faster growing and disease resistant trees. Timber related vegetation management practices that are expected to occur include; clearcutting, shelterwood seed cutting, partial removal methods and final removal.

Approximately 57,900 acres of mature and two-storied stands will be harvested using clearcutting and shelterwood methods. These acres will be re-vegetated using a diversity of trees, shrub and forb species.

Age class distribution changes will reflect the shift from mature and two-story stands to seedlings. It is anticipated all stands will be reforested within five years through planting and natural regeneration.

Vegetation: Forage

In the first 10 years, emphasis on management of forage will be placed on revision of outdated range allotment plans, and more intensive administration of existing range allotments. With updated management plans, enhancement of other resources through use of livestock will begin, but results will not be readily apparent until near the end of the decade. Increases in livestock use will be accommodated through more intensive management on existing allotments, or through conversion of existing sheep allotments to use by cattle.

Vegetation: Research Natural Areas

A viable network of Research Natural Areas will be recognized for the purposes of: Monitoring change; maintaining biodiversity (biological community, ecological and geological process maintenance), and researching natural ecosystems.

Water

During the next decade, the significance of water-related issues on the Forest will continue to build. The quality and quantity of water on the Forest will be significant concerns for diverse interests. Irrigation will continue to be one of the major uses of water from the Forest. Major emphasis will be placed on the protection and improvement of fish habitat both on the Forest and downstream.

In ten years intensified efforts will be underway on National Forest System lands to improve watershed conditions in some drainages, while existing conditions will be maintained in others. Factors promoting improved watershed management will include a greater emphasis in planning on a drainage basis, increased technical support, improved resource inventories, improved management practices, more aggressive watershed

DESIRED FUTURE CONDITION

and fish habitat improvement programs, and increased coordination of management activities with other ownerships and agencies. A primary objective will be to keep pace with State and Federal water quality management direction as it continues to be refined through the decade.

On the National Forest, water resource inventories will be scheduled and accomplished to meet the needs of project and Forest planning. A baseline and project level monitoring program will be in place to begin meeting the feedback requirements of both the Forest and the State in regards to management and environmental regulation. Watershed improvement projects will be identified and accomplished based on an updated needs inventory. For example, rehabilitation of the Holden Mine site on Lake Chelan will have been completed. Water rights necessary to achieve the multiple-use objectives of the Forest will be obtained in response to water resource developments and adjudications. All of these activities will be coordinated with other resources and management entities to a much greater extent than they are at present.

The overall condition of the water resource on the east side of the Cascades will be determined by the health of individual watersheds. These conditions will be the result of both management activities on National Forest System Lands, and management activities on other ownerships, both intermingled with and downstream from the National Forest. The net effect of these activities on area watersheds will be in large part dictated by efforts to achieve coordinated resource management planning among the various ownerships.

Air

Application of statutes contained in the Clean Air Act and compliance with State and Local regulations will have resulted in no significant deterioration of air quality. Base level values for Air Resource Management will have been established.

Soil

By the end of the decade, Forest-wide soil productivity will be about the same as it was in 1989. Ten years is too short a time frame to detect any significant changes in soil productivity. Also, by this time some long-term soil productivity study sites will have been established on the forest. (PNW research - F.S. coop studies).

Best management practices (B.M.P.'s) are well accepted and are clearly understood by everyone on the forest. The B.M.P.'s will have been completely reviewed and revised at least once by the end of the first decade. Project work plans will call for more monitoring to ensure that Forest wide standards and guidelines have been met. The Order II level soil survey for all National Forest Lands outside wilderness, and the Order III level soil survey for all National Forest Lands inside wilderness, will have been completed by 1992. This soil information will have been installed into the Forest GIS data system, where it is readily available and can be easily updated as new or better information becomes available.

Minerals

Locatable minerals: Since the Forest Service has little influence on the demand for locatable mineral resources, the conditions it desires to achieve is that of being able to meet the established goal for mineral resource management no matter what the demand is. That goal is to encourage and facilitate mineral activities over the Forest, while ensuring those activities are integrated with the use, conservation, and protection of all other resources.

Without new major discoveries, technological improvements, or substantial changes in the supply/demand situation, the number of mining claims will probably decline from 11,000 to the pre-Wenatchee gold rush number of about 4,000. The remaining claims should concentrate on areas having a known potential for the occurrence of locatable mineral commodities. Those claims will more accurately indicate where mining activities can be anticipated. This will be supplemented by an up-to-date mineral resource inventory and evaluation, and by industry's response to an

inquiry about where future mineral activities will occur. With this information, the Forest will be in a better position to appropriately plan and provide for future locatable mineral resource activities.

Leasable Minerals: As with the locatable minerals, the interest in these mineral commodities is likely to decline. Without a return to the energy shortages of the 1970's, the number of oil, gas and geothermal lease applications will decline and interest in leasing coal will remain negligible. Geophysical surveys and exploratory drilling for oil and gas in the Columbia Basin area will provide better information as to where and if oil and gas resources are likely to be found on the Wenatchee National Forest. Geothermal investigations may also be performed, which will better delineate areas having geothermal resource potential. Based upon this newly acquired data, the remaining leases will concentrate on areas with a high potential for the occurrence of energy minerals. The Forest will then be in a position to concentrate its management efforts on those areas where full scale development is anticipated.

Common Variety Minerals: The public's interest in these mineral commodities will continue at about the present level. The resource will continue to be inventoried to identify sources needed for specific projects. Where shortages are identified, the resource will be preserved to ensure adequate supplies are available to serve the needs of the Forest. A Forest-wide appraisal of mineral materials will be completed, and up-to-date fair market values for sales of a small scale will be established. The result will be better service to those demanding the use of this resource, and a better return to the public for the use of the resource.

Recreational panning, sluicing, dredging and rockhounding: The demand is expected to continue to grow in the future. Areas which would provide land that are available for such activities will be identified within the next 10 years, and management plans for managing the activities will be developed and implemented. The program will provide an opportunity for a type of recreational experience which has been extremely difficult to achieve. The implementation of a management plan will effectively mitigate the

impacts of activities which are often detrimental to the fisheries habitat and the riparian environment. It will also help eliminate civil conflict presently arising as a result of persons conducting such activities in areas already encumbered by mining claims, and it will allow such activities to be carried out legally.

Lands

Landline Location: About 90 percent of the Forest's property lines will be surveyed, marked, and posted to Forest Service standard, and will be on a maintenance schedule.

Cost Sharing: All major joint roads will have been identified with Plum Creek Timber Company and the Longview Fibre Company. Cost sharing on these roads will be completed. New work shared will be limited to reconstruction and occasional short segments of spur road.

Rights-of-Way Acquisition: If no significant changes in landownership occur, purchase of road and trail easements will still be in progress at the rate of about four per year.

If the major landowners within the Forest dispose of significant portions of their holdings, and these become small ownerships, the number of easements needed to provide adequate public and administrative access will multiply.

Purchases: The need for acquisitions within the Chelan, Lake Wenatchee, and Icicle Composites will continue. The purchase of the land in fee and the purchase of partial interests, such as scenic easements, which meet both the private and public needs, will both occur.

Land Exchange: All current land exchanges will have been completed.

The final phase of the program with the Washington State, Department of Natural Resources, will be nearing completion.

Further exchange with the Longview Fibre Company will be to "clean-up" any remnant of the two ongoing exchanges or to meet some site specific public need.

DESIRED FUTURE CONDITION

Small, site specific exchanges, involving areas where public and private needs coincide will continue with BN Inc. and other land owners.

Mixed Ownership Land Management: The current changes in the ownership and use of intermingled private lands will be much advanced and ongoing. Much of the larger ownerships within and adjacent to the Forest will be broken down into small (1-20 acre) ownerships. Uses will have changed from farm/ranch and timberland to primary and recreation residence or other types of recreation development. This change of land use will probably include those Plum Creek Timber Company and Longview Fibre Company lands which have highest and best use other than growing commercial timber crops. Their continued ownership and timber management efforts can be expected to be limited to those lands best suited to timber production.

The impacts of the "urban-wildland interface" will have multiplied. The Forest will be increasingly impacted by the fire, water, traffic, and pollution impacts of the thousands of small landowner neighbors. Close coordination with county road and planning departments will be a major factor in National Forest management.

These neighbors will be extremely sensitive to the management of the National Forest lands around them. Areas of particular sensitivity will be timber harvest, visual quality, road management, and soil and water quality.

Interchange: There is an existing proposal for public domain lands managed by the Bureau of Land Management in the State of Washington to transfer to National Forest management early in the 10 year period. If this becomes a reality, these lands should be completely incorporated into the National Forest system by the end of the 10 year period. Ideally, the Forest Service will also take over the management of the mineral resources on both the transferred lands and the existing National Forest lands.

Utility Corridors: It is anticipated that the existing corridors will meet regional needs through the next 10 years. The carrying capacity of these existing corridors will be increased. The proposed corridor, which will utilize a "window" in the

Sheets Pass to Pyramid Pass area, will not be needed during this period.

Small Hydroelectric Development. Two or three of the existing proposed developments will be completed. These will probably all be "retrofits" of existing water storage projects. The most likely candidates are the Tieton and Clear Lake projects and one of the Keechelus/Kachess/Cle Elum projects.

Asset Management Programs: Within the first 10 year period, the Forest will be asked to identify saleable parcels of National Forest land. The study will focus on small, isolated parcels of land, difficult to manage and not well suited to National Forest management. Before the end of the 10 year period, the study will be completed and sale of surplus parcels will have begun.

Encroachment and Title Claims: The current cases requiring litigation will be resolved. The current backlog of cases will be resolved. New cases will be resolved promptly using a variety of methods, depending on the circumstances of each case.

Roads

The level of road building activity will be comparable to the current level of approximately 80 miles of timber purchaser and 18 miles of arterial and collector road construction and reconstruction.

About the same amount of the Forest will be accessible to passenger cars and high clearance vehicles as today. Most newly constructed roads will be closed.

Biodiversity

Biodiversity will be an important issue at the end of the first planning decade. The concepts of preserving biodiversity on National Forest System Lands will be better understood and the establishment of quantitative goals will be possible. The Forest will be actively pursuing the goal of biodiversity maintenance or enhancement. Assessment of biodiversity will be commonplace and

regularly done in project planning. Geographic Information Systems will be on board and heavily used in this assessment process. Efforts will be ongoing to better quantify and classify diversity needs. It will be recognized at the end of the first planning period that land allocation changes will be required to maintain or enhance biodiversity.

THE FOREST IN FIFTY YEARS

Recreation

The overall management of the Forest will be strongly influenced by the recreation demands and needs being placed on it as the National Forests, in general, play a much expanded role in the national recreation picture. The economic benefits related to recreation will have considerable influence on Regional and local economics. There will be a wide diversity of both developed and dispersed recreation opportunities as described by the Recreation Opportunity Spectrum Classes. The acres managed in each class may vary depending on changing priorities over 50 years, however, there will be a balance of opportunities based on recreation demand.

Additional developed recreation sites will be added and existing sites expanded to meet growing needs of the public for outdoor recreation. There will be a wide variety in levels of development provided, based on changes in recreation activities and increased sophistication of public desires and expectations.

The PAOT capacity of developed recreation sites will have increased significantly. By the end of the second decade the capacity of Forest recreation sites will increase by 3,300 PAOT. Comparable increases can be expected in the private sector facilities as well.

Recreation use may be expected to be more balanced between winter and summer as the demands for more developed winter recreation opportunities continues to grow.

Dispersed recreation sites and areas will continue to provide the greatest capacity for recreation use of the Forest and play a more significant role in

the recreation program. Visitor use can be expected to reach or approach carrying capacities in many areas in the later decades of the next 50 years. Rationing of use through people-at-one-time quotas, entry permits, controlled entry stations, and reservation systems will likely be much more common. Special programs will have been developed to assist users in obtaining reservations and to help them find a location for the recreation experience the desire. Marketing studies and analysis will be an integral part of recreation planning and management.

Unroaded areas will be more important in the spectrum of recreation opportunities as a result of their gradual decrease in size due to roading for management activities. In the the third, fourth and fifth decades the allocated unroaded areas will remain constant at 298,115 acres.

The Forest will be used by a greater cross-section of the American people and foreign visitors. The biggest increase will likely be in people living in urban centers of large cities as they learn more about their National Forests. The Forest will receive a less proportionate increase in use from local users and will be much more a National resource.

Commercial enterprises and private investment will provide a greater portion of the developed recreation sites and facilities. User fees will continue to be a primary means to support administration and maintenance of recreation sites.

Reservation sites and increasing facilities for group recreation will be developed to improve public service.

New technologies and improved equipment will generate new recreation activities. These in turn will generate a need for more intensive management of people and activities, as well as much more complex administration.

Management actions designed to allow for the greatest mix of activities to occur without conflict will be implemented. These may include: special zoned areas for specific uses; rotation of uses and users on the same site, trail, or within the same area; and more use of assigning where, when, and how long visitors can use the Forest through the

DESIRED FUTURE CONDITION

issuing of passes, permits, et cetera. Some sites or areas may be "rest rotated" to allow for natural healing or for major maintenance. Vegetation management will be practiced in many sites to provide for the long-term succession of the desired vegetation.

Improved transportation systems will enable more distant visitors, both foreign and domestic, to enjoy the Forest's varied offerings. Perhaps these visits will be part of tour packages designed to sample a broad spectrum of experiences across the country over a relatively short period of time. "State of the art" high-tech monitoring devices will be in place to aid in data gathering, surveillance, control, and management of many resources including recreation activities.

Wilderness

The acreage of designated Wilderness will likely be the same, or very similar to the current designation. Some potential additions or declassifications are possible depending on changing priorities or demands for Forest resources.

Increasing levels of visitor use in most accessible areas will necessitate greater restriction of visitor activities. Most Wildernesses will be under permit systems or some other means to strictly control numbers of people in each Wilderness at one time. The exact carrying capacities will fluctuate over time based on users ability to practice low impact techniques. Changes in Wilderness resource conditions will be stable to improving as a result of education programs, regulation and restriction of visitor use, and biological resource rehabilitation.

Forest Wildernesses will continue to provide a wide variety of recreation activities and opportunities compatible with management of Wilderness.

Fire will return to its natural role in Wilderness ecosystems through management of prescribed fire and the gradual deterioration of natural fuel accumulations. Perhaps only fires that threaten life, property, or resources outside of Wilderness will be suppressed.

Cultural Resources

The future of the cultural resource program 50 years from now is difficult to project. Within the second decade, it is likely that all suitable timber lands will have been surveyed for cultural resources. As mentioned in the 10 year projection, about 25 percent of these acres will require further investigation--additional surveys, project monitoring, or subsurface testing. These efforts are likely to locate sites that were not identified in the initial survey efforts. Furthermore, an additional 50 years of history will have augmented what is currently recognized as the cultural resource base with a number of new historic sites and structures. This may require reevaluation of some lands and modification of proposed project plans.

Whereas site avoidance was more easily practiced in the first harvest entries, successive entries in areas of known cultural resources may require more extensive mitigation measures than were needed in the first decade. By the end of the fifth decade, the number of non-significant sites initially identified will have decreased due to project impacts, after adequate documentation has taken place.

Provided funding is available, a systematic inventory will have extended beyond those lands suitable for timber harvest, ideally covering an additional 600,000 acres of backcountry and wilderness. Knowledge of site types and distributions will be greatly enhanced. The Forest will be closely linked with the rest of Washington State in cultural resource management through coordination of its program with the Washington State Historic Preservation Plan. Emphasis will be on thematic, geographic, and/or chronological groupings of sites, so that individual sites can be assessed and managed within the appropriate historic context. This context will have State-wide perspective, and will be the result of long-term coordination with other Forests, agencies, and institutions in the State, as well as with the Washington State Office of Archaeology and Historic Preservation.

The backlog of sites on the Forest requiring adequate documentation will be completed. The SI-2 prescription may cover as many as 7,300

acres of cultural sites on the Forest (depending upon the amount of area needed to preserve and enhance cultural values). Management plans will be completed on all National Register eligible sites that are known today and, with the help of interested volunteer groups, there will be some interpretation of these sites.

Some areas of the Forest (particularly the south end) will continue to be of special concern to the American Indian community. Expanding development and pressures on the Reservation may encourage increased Indian use of the Forest lands and resources for traditional subsistence and religious purposes. Unless there is Congressional action to the contrary, treaty rights will remain paramount. By the end of the fifth decade, those geographic localities and resources of special concern and interest should be clearly defined and understood. There should be a smooth process for coordination with the Indian groups, an understanding of their heritage values, and a reflection of this in the implementation of management practices on the ground. There may continue to be some areas of disagreement where compromise will be necessary. Depending upon the management practices carried out on intermingled private land on the south end of the Forest, some adjustment in land management allocations may be necessary.

Fifty years of studying, reflecting upon, and managing the cultural resources of the Forest should greatly enhance our awareness of the human dimension within the forested environment. It may contribute to an appreciation of our own unique history as a land managing agency. And on a larger scale, it will make an inestimable contribution to the story of human development through time and across the diverse geographic spaces of the Cascade Mountains.

Scenery

The maintenance, enhancement, rehabilitation, and perpetuation of scenic qualities through visual resource management in key areas will continue.

Most existing, natural appearing landscapes in recreation sites and recreation viewsheds will be protected through careful management. The managed appearance will retain a high degree of naturalness with a wide variety of vegetative composition. Some areas will appear relatively unchanged. A variety of small openings, areas of shelterwood timber harvest, clumps, and individual large trees intermixed with smaller ones will be blended with the unmanaged vegetation. A two story or multi-level appearance will be characteristic of timber stands in areas where harvest has previously occurred.

The Forest will begin to change from the dense natural wild condition to a variety of stand densities. Large mature trees will be accentuated along scenic viewsheds and travel routes. A variety of age classes, species, and multi-level stand compositions will be evident. These managed tree compositions with associated understory vegetation will be very pleasing visually. Mosaic patterns of texture, line, color, and form changes will be interspersed throughout the existing textural patterns. Viewsheds within areas of intermingled ownership will be more visually appealing as these areas become forested with young trees.

Non-timbered areas will remain basically unchanged in appearance. Where forest and natural openings are intermingled, the general visual character as viewed from a distance will be similar to today.

The general appearance of the rest of the managed forest outside important viewsheds will be a mosaic of cutting patterns of varying size, shape, and arrangement. This area will have the appearance of an intensively managed, smaller diameter, renewed young forest.

Wildlife and Sensitive Plants

Bald eagle nests are expected to increase to 8 or 9 sites on the Forest in 50 years. Roost sites will be located and protected, and feeding areas managed for the eagles. Bald eagle sightings will be common due to increased habitat and increases in fish and waterfowl numbers from habitat improvements.

Peregrine falcon sightings will not be unusual and one to three nest sites may be active on the Forest.

Sensitive plants and animals will have Species Management Guides. This direction should reduce conflicts and reduce threats to these species. Most sensitive plants have been located. All known sites are mapped and are entered on the Forest Geographic Information System. The Wenatchee National Forest is recognized for the high number of unusual plant species existing on the Forest. Recreationists will be able to visit some of the sensitive species sites and enjoy knowing these species are being maintained or increased in population.

The habitat carrying capacity for deer and elk will decrease slightly from 1989. Changes will be due to management prescription for winter range, habitat improvements, and sensitivity of activities to spring and summer habitat. Hunting opportunities will have increased but quality of the hunt may decrease.

Old growth habitat will have decreased to near its lowest levels for ponderosa pine, Douglas-fir, and grand fir. Spotted owl numbers will decrease to the level that will be maintained in the future. From research and monitoring of the old growth habitat, most people will be confident that species dependent upon old growth will be here for another few hundred years. Means of viewing these species will be highly developed and many recreationists will visit the Forest to see spotted owls and the species dependent upon old growth.

Primary cavity excavator habitat will be at its lowest level or already beginning to increase in Forest-wide amounts. Habitat will be well distributed. Forest visitors will be able to enjoy seeing and hearing this group of species no matter where they go on the Forest. Recreation developments such as trails, blinds, and viewpoints will have provided an abundance of opportunity for viewing.

Forest-wide standards and guidelines provide for maintaining habitat for mountain goats. Seventy-five percent of the mountain goat habitat is in wilderness and the populations there will either maintain or decrease slightly as activities increase. The other 25 percent of the habitat will have increased activities. This will decrease populations, but habitat improvements will offset losses of habitat. This direction will limit conflict and allow for at least maintaining the mountain goat populations. If populations suffer from unanticipated problems, additional goats can be reintroduced to maintain populations.

Old growth and mature habitat will be abundant in wilderness and roadless areas. The roaded part of the Forest will have islands that are interconnected into a network that maintains distribution and species viability. These islands will stand out when viewed from high points or airplanes. They will enhance the diversity of vegetation and texture seen. Some recreation development may have been done to allow enjoyment of these areas by wildlife watchers.

Trapping of furbearers will have declined due to public pressure, but viewing of these species will have increased. Some species will be low in numbers but not near to being listed as sensitive.

Grouse management will be advanced and high numbers are anticipated. Long hunting seasons and viewing opportunities will be common. Habitat manipulation and improvements will be common. Demand will, at some point, exceed potential to produce these species.

Limited habitats such as ponds, caves, and cliffs will have intensive management plans that call for maximum recreational use and high populations of wildlife in their natural setting. Tours will be in high demand and population viability will not be threatened.

Owl and hawk nests will mostly be known and managed. Sightings of owls and hawks will be common due to design of timber sales, roads, trails, and habitat improvements.

Old Growth

It is estimated that by the end of the fifth decade there will be 261,200 acres of old growth remaining on the Wenatchee. In the next fifty years there should also be some ingrowth that will increase the actual acres of old growth on the Forest above this amount. By that time there will be a good understanding of the old growth ecosystems and their role in maintaining such things as long-term forest productivity and biological diversity. The rate of ingrowth of natural stands to an old growth condition will have been quantified (Currently none of the estimates of old growth remaining on the Forest have included ingrowth). Changes in standards and guidelines to reflect increased knowledge of old growth will assure that biological diversity, aesthetics and wildlife and plant habitat that the old growth ecosystems provide will be maintained.

Fisheries

Fifty years from now, demand for both anadromous and resident fish and fishing opportunities will remain high. Fish production goals established fifty years ago will have been met. Actual production levels will depend upon society's demand for various resources including irrigation, timber, recreation and power. The state of technology for fish and fish habitat management has advanced greatly since the 1980's providing managers with improved predictive ability when considering trade-offs between resources. Due to continued high demand for fish and good water quality, riparian areas will be in conditions which will provide habitat for fish production goals. Desired fish and riparian habitat conditions will be well described. The Forest will be in a mode of monitoring past and present actions. There will have been numerous refinements in management practices and prescriptions based upon monitoring and research. Habitat improvement projects will continue into the future and the Forest will be rebuilding and maintaining structures constructed in this time period.

Riparian Areas

By the end of the fifth decade, riparian management objectives for sub-drainages on the Forest will be highly refined. The trends established during the first decade in regards to inventory, monitoring and refinement of management techniques will have continued, resulting in the maintenance of excellent water quality and provision of diverse, high quality riparian habitat. This habitat condition will maximize the production potential of riparian dependent species. The desired future condition for the major elements of riparian habitat listed in the "Forest in Ten Years" section will have been achieved, although major improvement in the process and standards used to evaluate this will have been made.

Vegetation: Trees

One of the biggest changes will be the forested appearance of the large areas denuded by fire in 1970 and 1988 on the Chelan and Entiat Districts. Where wide vistas now occur on these Districts, trees 60 to 80 feet tall will be present. Some limited commercial thinning may be taking place where economics and technology permit.

Almost all stands suitable for timber harvest will have some level of harvest. An estimated additional 348,000 acres will have been changed from wild to managed stand conditions. This is 73 percent of the existing suitable mature and two-storied stands. See Table IV-1 for a listing of harvest acres by watershed.

Reforestation seed will be primarily from select trees that have shown disease resistance, and better form and growth qualities.

Average tree growth rates will be increased, with much less defective down woody debris being available for fuelwood gathering. Wildfire potential and damage will be greatly reduced in roaded areas. Accumulations will continue to build in unmanaged areas with some presently large open areas in wilderness completely overgrown with trees.

Some new openings created by wildfires may be present especially in unroaded recreation and wilderness areas.

Vegetation: Forage

By the end of the 50 year planning horizon, most of the 200,000 acres of suitable livestock range within allotments will be under some form of grazing management. Resource managers will be using livestock as a tool to manage the vegetative resource. Analysis of allotments will be ongoing with about 10 percent of the existing allotments reanalyzed annually.

Over 85 percent of the suitable livestock range will be in an improved forage condition with an upward trend in ground cover and species composition. These improved forage conditions will contribute to the protection of soils and watersheds. Not all of the suitable livestock range will be used each year. On key big game range for example, livestock will be used only to maintain the already improved big game forage, or occasionally to utilize forage in excess of game needs. Forage production on the Forest will still exceed the amount needed for big game and livestock, even though the numbers of big game and livestock using the Forest have increased each decade.

Permanent range improvements will still be installed and maintained. However, many fences and water developments will utilize materials which can be easily moved from one location to another. These temporary improvements will allow managers more flexibility in treating site specific areas, such as riparian zones and forage areas created through timber harvest.

Vegetation: Research Natural Areas

A viable network of Research Natural Areas (RNA) will exist on the forest and will be used to meet the goals listed in the Forest Service Manual. Additionally, RNA's will be used for monitoring change in commonly harvested natural plant associations, and will be recognized for fulfilling part of the needs for biodiversity.

Water

Within five decades, water-related issues will have become a dominant factor in Forest management. Upland water quality and riparian area condition will be major issues due to many factors, including the levels of recreational use along Forest streams, lakes, and rivers. Increased demands for quality fish habitat will place great emphasis on watershed protection and maintenance of minimum flows. Although irrigation demands will probably be about the same as they were in 1988, there will be a conversion from commercial orchards toward urban use. The overall demand for water for human use will increase, and adjudication of the water rights on nearly every major drainage on the Forest is expected.

Fifty years from now, watershed conditions on National Forest System Lands should be improved over current conditions. The factors promoting this improvement will be much the same as indicated for the first decade, although the effect of the factors over time will increase as a greater emphasis is placed on watershed resources. Management standards and guidelines will have changed significantly to satisfy refinements in State and Federal water quality standards and other environmental regulation.

By the end of the fifth decade, several revisions of the water and other resource inventories will have been completed over the entire Forest. Resource information of a much greater quality will be available for use in making management decisions. Feedback from the Forest monitoring program will have resulted in numerous refinements in management practices and prescriptions. The backlog of watershed improvement projects will have been eliminated, and newly identified improvement needs will be treated. Water rights adjudication will have been completed on many of the major watersheds on the Forest. The identification of instream flow needs for channel maintenance, fish habitat, and other purposes will have received much greater emphasis than in the past. Coordination of management activities with other resources and management entities will receive greater emphasis.

TABLE IV-1
ACRES AND PERCENTAGES OF LAND ALLOCATIONS BY WATERSHED 1/

Watershed	Total Acres (Gross)	Private		Wilderness		Intensive Harvest		Other Harvest		Non Harvest

1/ See FEIS, Appendix F for explanation of headings

DESIRED FUTURE CONDITION

Watershed conditions in the region fifty years from now will be determined by the net result of management activities on all ownerships. Public interest will have fueled major efforts in coordinated resource management planning. Watersheds in which these efforts were successful will be characterized by some level of multiple use output on all ownerships. Watersheds in which efforts at coordinated management planning were less successful may be subject to much more heavily constrained outputs on some or all ownerships. See Table IV-1 for a listing of the acreages and percentages of land allocations in the 25 Forest watersheds.

Soil

By the end of the 50 year planning horizon, there will be less soil erosion and less delivered sediment entering the streams, lakes, rivers, and reservoirs, because the Best Management Practices (B.M.P.'s), along with the Forest Wide Standards & Guidelines are being closely followed. Both the B.M.P.'s and the Forest Wide Standards and Guidelines will have been revised and fine tuned to the point that soil degradation is well within commonly accepted levels. Maintaining or enhancing soil productivity will be an important issue in most land management decisions.

There will be increased emphasis on soil productivity, so the Forest will be requiring the use of timber harvest systems and techniques that minimize soil degradation. Land managers will be familiar with the location and extent of the more productive soils, so that they can take full advantage of intensive forest management practices on those soils. (ie. thinning, fertilizing, etc.).

By the end of this period, there will be more detailed soil information available (higher order soil survey information, more laboratory data, and more flexibility for developing site-specific interpretations for the land managers). The availability of this kind of information will be very important, because the land managers will probably be under more pressure to protect the environment, particularly water quality and soil productivity.

The Forest Soil Scientist will be using the GIS data management system for developing interpretative information for the Forest Land Managers.

Research and Forest personnel will be periodically monitoring the selected long-term productivity sites on the Forest. The fifty year results of this monitoring will not (according to researchers) be a long enough period of time to obtain any significant results. In fact, because of the importance of this issue for management, it may well be that there will be some additional soils added to this study.

Air

Continued monitoring and enforcement of National, State, and Local regulations will show a significant improvement of the Air Quality Related Values above the base level. Research into Air Quality problems will be at a high level.

Burning forest residues on-site will probably be done only in special cases. Specialized markets for forest residues will probably be created that will end up being the preferred use for this material. Also, burning constraints will probably be imposed on homeowners that will make wood stoves and fireplaces much more expensive and less desirable to use.

Minerals

Locatable minerals. The supply/demand situation will have changed considerably, accompanied by a number of technological improvements in mining, recovery, and reclamation methods. As a consequence, more locatable mineral-related activities can be expected. The Forest will have completed an up-to-date mineral resource inventory, and will have established good communication with those interested in mining on the Forest. As a result, the Forest will have a thorough knowledge of what, when, and where mineral activities will occur, and will be in a position to pro-actively manage for these activities. Successful reclamation techniques will have been identified. There will be no undue or unnecessary degradation of the environment caused by mining; the adverse impacts caused by these activities will be short-term; and mineral activities will have been ac-

cepted by the public in general as a land use that is not only necessary, but totally compatible with other resource uses.

Leasable minerals: We will have returned to an energy shortage situation, and will be in the process of developing marginal or newly discovered oil and gas resources as well as alternative sources of energy such as coal and geothermal. Those areas having a high potential for development will have been identified, and full-scale development of the resource will proceed in a manner consistent with this plan.

Common variety minerals: The Forest will intensify its materials resource inventories in areas where mineral materials are scarce. Resources critical to the Forest Service road construction and maintenance activities, critical to other public works projects, and necessary to meet anticipated demand by the public sector will have been identified and reserved for future use.

Withdrawals: All withdrawals will be periodically reviewed at 5 to 20 year intervals. The review will consider any new land management regulations which would provide adequate protection, as well as any new mineral resource information (exploration data, economic data, supply/demand data, etc.). All unnecessary withdrawals will have been eliminated.

Recreational panning, sluicing, dredging and rockhounding. The demand for recreational panning, sluicing, dredging and rockhounding activities will continue to grow. However, our ability to provide for the demand may not increase because the areas where such activity can be conducted are limited by the occurrence of mineral resources and the legal status of lands. The management plans implemented for this activity will have been in place and any problems with the management of the activity will have been resolved. As a result, we will be able to better serve the public who has an interest in conducting these activities.

Lands

Landline Location: All needed property lines will be surveyed, marked, and posted to Forest Service standard. Maintenance will be ongoing under a maintenance plan and will be current. Where needed, wilderness and other designated area boundaries will also be surveyed, marked, and posted, and on an adequate maintenance schedule.

Cost Sharing: Activity will be limited to reconstruction and maintenance of jointly used roads.

Right-of-Way Acquisition: All necessary road and trail right-of-ways will have been acquired.

Purchase: Purchases will be limited to infrequent, small, site specific needs--usually to facilitate a special need or project requirement.

Land Exchange: Land ownership adjustments via exchange will be completed except for infrequent, small, site specific cases needed for the same purposes as Purchase, above.

Mixed Ownership Land Management: This situation will have stabilized. The Forest's working relationship with neighboring landowners, and local and State agencies, will be well-defined and ongoing.

Interchange: Land transfers with other Federal agencies will be completed. Questions of management authorities and direction will have been resolved.

Utility Corridor: Existing corridors will have been developed to capacity. The proposed corridor will have been developed and will be in use.

Small Hydroelectric Development: All viable small hydroelectric sites will have been developed. Output from these sites will be ongoing.

Asset Management Programs: Land ownership adjustments via this program will be complete before the fifth 10 year program.

Encroachment And Title Claims There will be very little activity in this area by the fifth 10 year period. It will probably be limited to an occasional exchange of a quitclaim deed to remove a cloud on the title of either a National Forest parcel or an adjacent private land parcel.

Roads

The road system should be completed and under management. Only an occasional short road will need to be constructed for managing the surface resources.

Access may still need to be granted to utilize mineral resources.

The level of residential development within and adjacent to the Forest will have progressed to the point that county agencies will manage a portion of the current Forest road system to provide for mail, school, commercial, and other public road uses.

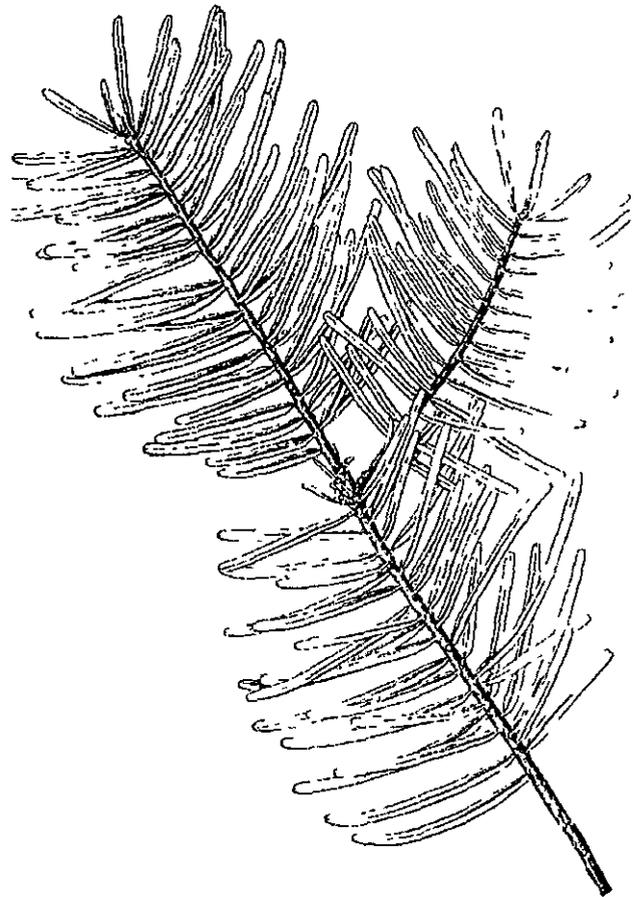

Biodiversity

Biodiversity will be recognized as a very critical issue in National Forest System Lands management. The interrelationships of biodiversity and subordinate issues such as forest fragmentation, old growth, long-term productivity, rare plant conservation and flow of genetic material will be understood and applied in forest planning and management. A classification and inventory system will be well developed and heavily used as tools to assure maintenance of biodiversity. The Wenatchee National Forest will be recognized for its role in maintaining the animal and plants found there and the communities in which they are a part.

D. FOREST MANAGEMENT OBJECTIVES

The annual levels of goods and services are estimates of what may be produced from the Forest when this plan is implemented, are summarized in Table IV-2. These outputs and activities are resource management objectives for the Forest. Table IV-2 also contains the annual funding levels necessary to meet the proposed outputs and activities. If final budgets are significantly different than those contained in the table, the final outputs of goods and services will vary according to the funding level.

A narrative description by resource follows the Table summaries.

RESOURCE NARRATIVES

1. RECREATION SETTING

a. Recreation Opportunity Spectrum

The goal of the recreationists in visiting the Forest is to obtain satisfying experience and to *meet expectations in recreation activities*. An objective of the Forest Manager is to provide the opportunities for these expectations to be realized. Recreation opportunities can be broken down into three components; activities, the setting, and the experience. The quality of the setting available for the activity plays a key role in the outcome of visitor's expectations.

The Forest has the potential to provide a wide variety of recreation settings. In order to help identify, quantify and describe these settings, the Recreation Opportunity Spectrum (ROS) has *been developed*. The ROS system *arranges the possible combinations of activities, settings, and probable experience opportunities across a continuum or spectrum*. The spectrum ranges from primitive to urban and has the following seven classes:

1. ***Primitive:*** An area characterized by an environment essentially natural and unmodified by human influence and development. Here there is a *high probability of experiencing solitude and isolation from the sights and sounds of human activity*. The area is located at least 3 miles from all roads, railroads and trails with motorized use, and is at least 5,000 acres in size. Few people will be seen or encountered here and regimentation and on-site controls are few.

2. ***Semi-Primitive Non-motorized:*** An area characterized by a predominantly natural or natural appearing environment. Here there is a high probability of experiencing solitude and isolation. The area is located at least 1/2 mile, but not generally further than 3 miles, from all roads, railroads or trails with motorized use. The area is at least 2,500 acres in size. Other people may be seen or encountered in this area, but not frequently. On-site controls and regimentation will be present but subtle.

3. ***Semi-Primitive Motorized:*** An area characterized by a predominantly natural or natural appearing environment. Here there is evidence of other users, but concentrations of users are low. There is a moderate probability of experiencing isolation and solitude. The area is located within 1/2 mile of primitive roads or trails used by motor vehicles, but not closer than 1/2 mile to roads of a higher standard than primitive. The area is at least 2,500 acres in size. Other people will be seen or encountered but not frequently. On-site controls and regimentation will be present but subtle.

4. ***Roaded Natural:*** All area predominantly natural appearing. Vegetation management and resource modifications are present but harmonize with the natural environment. A moderate opportunity exists for isolation and undisturbed activities. The area is located within 1/2 mile of better than primitive roads and railroads. There is a moderate to high probability of contact with other people on roads; low to moderate probability off roads and on trails. On-site regimentation and controls are generally noticeable.

5. ***Roaded Modified:*** An area that is generally natural appearing but has significant vegetation management and resource modification. Modifications generally harmonize with the natural environment. A moderate opportunity exists for isolation and undisturbed activities. The area is located within 1/2 mile of better than primitive roads and railroads. There is a moderate to high probability of contact with other people on roads; low to moderate probability off roads and on trails. On-site regimentation and controls are generally noticeable.

6. ***Rural:*** An area characterized by a substantially modified natural environment. Vegetation management and facility development is dominant. Here there is a moderate to high frequency of contact with other users in developed sites, on roads and trails, and on water surfaces. Many facilities are present to handle groups as well as individual users. Regimentation and managerial controls are numerous; but largely in harmony with the natural environment.

7. Urban: An area characterized by a substantially urbanized environment, although the background areas may have natural appearing elements. Developed sites will have the highest standard of development with many user conveniences. The setting is strongly structure dominated. Large numbers of users will be present on site and in nearby areas. Regimentation and management controls will be obvious and numerous.

b. Developed Recreation

The Developed Recreation sites and facilities will be significantly upgraded and improved over the life of this plan. Major emphasis will be placed on:

1. Rehabilitation and reconstruction of developed sites that need extensive repair and refurbishing. Sites with high visitor use will receive highest priority. Sites that currently have user conflicts will also be high priority when redesign and reconstruction can help solve user problems.

2. Improvement in the quality of facilities provided at developed sites and the type of facilities provided. Improvements will be designed to provide a high level of user satisfaction and user preferences will dictate the type of facilities constructed, and what activities are possible at each site.

3. Expansion of existing developed sites where overcrowding of the sites and adjacent areas has resulted in health and sanitation problems, undesirable loss of vegetation and soil compaction and user conflicts.

4. Construction of new sites where recreation area planning indicates sufficient public demand exists and where high quality opportunities are present.

Under this emphasis, most of the popular campgrounds, picnic areas, and interpretive sites on the Forest will be upgraded. Major trailheads will be upgraded with more user facilities. More interpretive sites will be developed. Campgrounds where fees are charged will continue on the fee system. Many of the upgraded facilities will be

added to the fee system (refer to Appendix A for a list of sites planned for rehabilitation, upgrade, or expansion during the next 10 years).

There will be more emphasis on partnerships, cooperative efforts, and joint ventures with other agencies, organizations, clubs, and private businesses in the planning and financing of developed sites. When economically efficient and service effective, more sites will be considered for operation under contract by concessionaires. Maximum opportunities will be sought to expand facilities and services through Challenge Grants, Cooperative Funds, Foundations, and Federal Capital Investment. The use of volunteers will continue to provide a significant benefit to the management of programs.

Ski area expansion is under consideration and in planning stages at Mission Ridge and White Pass. Further expansion will be commensurate with growth of demand for skiing recreation.

Timber sale activities will continue to provide opportunities to expand and improve trails, trailheads, dispersed camping, viewpoints, and parking areas for recreation activities.

Management of other types of developed recreation, organization, and club sites, Recreation Residences, etc., will continue. Any increase in activity or new proposed development will be analyzed in terms of recreation opportunities, recreation user demand, and public service.

c. Dispersed Recreation

The dispersed recreation program will receive the same emphasis as the developed recreation program, of establishing partnerships, joint ventures, and cooperative efforts in providing high quality recreation opportunities for Forest visitors.

Dispersed recreation opportunities will be planned to provide potential for a wide diversity of activities for the recreating public. The management of dispersed areas and the construction of facilities to support dispersed recreation activities will conform to the Recreation Opportunity Spectrum class to provide a consistent setting.

Winter sports activities such as snowmobiling, cross-country skiing, snowshoeing, dog sledding, and snowplay will continue to grow in popularity and receive management emphasis. Trail marking, grooming, and track setting will continue to be done in cooperation with the State Parks Division and user groups as well as under permit.

Many dispersed recreation activities will be supported or made possible by cooperators or the private sector, such as recreation organizations, clubs, and commercial outfitter-guides. In activities such as river rafting, fishing, backpacking, hunting, climbing, and ski touring, experienced guides or outfitters will continue to provide these opportunities for the public.

Transportation planning and management will continue to recognize driving for pleasure as a major activity on the Forest Road System. Estimated recreation use and recreation opportunities will receive greater consideration in the construction design and maintenance standards for the road systems. More roads will be located and constructed primarily for recreation management objectives, and more in conformity with Recreation Opportunity Spectrum setting criteria. Appendix A contains a list of proposed recreation road construction projects for the next 10 years.

d. Trails

The Forest Trail System will provide a full array of recreation activities and experiences and will provide access to a wide range of destination and focal points of interest. The trail system also will provide access for Forest Administrative actions. There are 2,463 miles of trail on the Forest in Recreation Opportunity Classes from Primitive to Rural. Trail maintenance will be performed on all of the 2,463 miles of trail each year, depending on budget and the availability of volunteers.

Major reconstruction, rerouting, and relocation work is planned on the trail system to provide improved recreation experiences, correct problems with excessive soil erosion and water sedimentation, and to meet recreation opportunity spectrum and wilderness management objectives.

It is expected that about 400 miles of new trail will be constructed by the end of the first decade. About 120 miles of this new construction will allow motorized use and about 280 miles will be constructed for non-motorized users. This will result in a net increase for motorized and non-motorized trails when both the existing trail system and future trails are taken into account. Motorized trails will show a net increase of about 65 miles and non-motorized trails will show a net increase of about 335 miles. Although not mandated by law or required by previous agreement, all trails that have been improved with Inter-agency Committee for Outdoor Recreation funds will remain open to motorized use.

The addition of new winter trails is planned to respond to growing demand for winter sports activities. Many new summer trails will also be added to improve conditions for existing visitor use and solve user conflicts. A list of planned trailheads, sno-parks, and trail projects is included in Appendix A.

Trail project planning and accomplishment will involve partners and cooperators to extend the financial scope of projects and provide greater recreation values.

e. Special Interest Areas

Special interest areas will provide places as needed to exhibit some of the unique attributes of the Forest. The Tumwater Botanical area and the Nason Ridge recreation area are two such places.

Formal classification and management plans will be developed for the following areas:

Area Name	Approximate Area	Recommended Classification
Teaway	47,900	Dispersed Recreation
Nason Ridge	10,000	Dispersed Recreation
Annette Lake	1,400	Dispersed Recreation

The establishment of these areas is recommended in the Alpine Lakes Area Management Plan and until formal classification and specific management plans are completed, their management will be directed by that plan.

2. WILD, SCENIC, AND RECREATIONAL RIVERS

Formal designation for selected rivers as Wild, Scenic, and/or Recreational will be pursued through implementation of this plan. The river segments listed below were found to be eligible and will be recommended to Congress as candidates for inclusion in the Wild and Scenic River system.

Designation of these rivers will preserve and protect scenery, recreational, geologic, fish, wildlife, historical, cultural, and ecologic resource

values within these stream corridors. The degree of protection will be commensurate with the classification. These rivers have been determined to provide high quality recreation opportunities and exhibit at least one outstandingly remarkable resource value. Recreation activities including water sports, viewing scenery, and camping would be enhanced through these designations. There would also be significant economic benefits generated through increased tourism and recreation visitor use.

TABLE IV-3

River	Segment	Recommended Classification	Miles
American	Headwaters to confluence with Rainier Fork	Wild	6.0
	Confluence with Rainier Fork to confluence with Bumping River.	Scenic	16.0
Cle Elum	Headwaters to Alpine Lakes Wilderness boundary	Wild	4.0
	Alpine Lakes wilderness boundary to above Lake Tucquala.	Scenic	2.0
	Above Lake Tucquala to Lake CleElum	Recreational	18.5
Waptus	Headwaters to confluence with Cle Elum River.	Wild	13.0
Icicle	Headwaters to Alpine Lakes Wilderness boundary.	Wild	12.0
	Alpine Lake Wilderness boundary to above Leavenworth city water intake.	Recreational	14.0
Napeequa	Headwaters to Glacier Peak Wilderness boundary.	Wild	15.0
	Glacier Peak wilderness boundary to confluence with White River.	Recreational	1.0
White	Headwaters to Glacier Peak Wilderness boundary	Wild	15.0
	Glacier Peak wilderness boundary to above Tall Timbers Ranch.	Scenic	7.0
	Above Tall Timbers Ranch to Lake Wenatchee.	Recreational	12.0
Chiwawa	Headwaters to Glacier Peak Wilderness boundary.	Wild	5.0
	Glacier Peak wilderness boundary to confluence with Wenatchee River.	Recreational	30.0
Wenatchee	Lake Wenatchee to Wenatchee Forest boundary.	Recreational	28.0
Entiat	Headwaters to Glacier Peak Wilderness boundary.	Wild	12.5
	Glacier Peak Wilderness boundary to Cottonwood Trailhead.	Scenic	4.0
	Cottonwood Trailhead to above the confluence with Burns Creek.	Recreational	15.0

3. CULTURAL RESOURCES

There will be close coordination between the cultural resource program and other resource management activities on the Forest throughout all decades. Approximately 400,000 acres of National Forest land (in addition to that already investigated) will be surveyed over the next 10 years in project support (i.e. surveys that precede any ground disturbing activities). Since most of this will be linked with the timber sale program, the annual increments will depend in large part upon the location and total land area included within anticipated timber sale areas. In addition, inventory will extend beyond the lands suitable for timber harvest, covering some 67,500 acres of high sensitivity areas, backcountry and wilderness. Information collected during all of these inventories will be used to refine the cultural resource sampling strategy used on the Forest.

Not all acres examined will be cleared of necessary cultural resource considerations. Approximately 25 percent of these acres will require further investigation due to known site distributions or because of high cultural resource sensitivity. Heavy monitoring emphasis will be given these localities.

The number of acres inventoried for timber support will drop in subsequent decades. By the fifth decade, inventory of all suitable timber lands will have been completed. A small number of inventories will continue in conjunction with Recreation, Minerals and Grazing, and Land Adjustments, and will probably remain at the current level through the second decade. Systematic surveys carried out as part of the cultural resource inventory program (not as project support) will continue to examine approximately 10,000 acres per decade.

In addition to the inventory of sites located during project-related survey, inventories will be prepared to Regional standards for the current backlog of unrecorded or insufficiently recorded cultural resources. The process will add approximately 15 sites per year will be added to the inventory base. This will enable the Forest to complete documentation of all existing properties by the end of the second decade. The resulting data base will contribute to State-wide efforts in

preservation planning, will facilitate the development of appropriate research strategies, will provide the basis for evaluations of significance, and will aid in the formulation of informed management decisions. This data base will allow the land managers to more adequately assess the uniqueness, cultural importance, regional associations, and ultimate worth of any cultural resources existing on the Forest.

As documentation of known sites is completed, site inventories will concentrate on newly discovered sites, resulting in a significant drop in the number of annually recorded sites by the fifth decade.

An assessment of significance is pivotal to management of cultural resources. It will influence the selection of sites meriting further considerations or investigation, as well as the decision as to whether to preserve or ultimately permit alteration or destruction of the resource. Approximately 12 sites per year through the second decade will be formally evaluated as individual properties, as thematic groups, or as historic districts. By the fifth decade, this number will drop, reflecting the decline in the number of sites remaining to be evaluated.

In the case of archaeological sites on the Forest, some test excavations will be necessary to determine the boundaries, depth of deposits, and/or basic nature and condition of the properties. Depending on the results of the testing, data recovery will be carried out on those sites where vandalism, project impacts, or natural degradation are occurring. Approximately five sites per decade may be excavated in consultation with interested American Indian groups, utilizing a professionally sound research design. This number may increase in future decades as avoidance of project impacts becomes less feasible.

Cultural resource management plans will be developed for selected National Register sites and districts on the Forest, in consultation with the Washington State Historical Preservation Office (SHPO). An average of 5 plans per decade will be completed, which will detail the management objectives for the subject properties, the treatment and actions necessary to achieve those objectives, interpretive opportunities, and the

costs involved. Two top priorities in the first decade will be the Stevens Pass Historic District and Salmon La Sac Guard Station.

The ultimate goal of the cultural resource program will be the scholarly use and/or interpretation of appropriate cultural resource properties for the benefit of the public. Forty such projects will be undertaken in the first decade. Additional projects will be added in subsequent decades, while existing interpretive facilities will continue to be maintained and updated. By the end of the fifth decade, there may be over 100 fully interpreted cultural resource properties on the Forest.

4. SCENERY

Visual quality is to be maintained at a high level for all major scenic highway viewsheds, the Alpine Lakes Management Unit, and most major wilderness portals. Maintenance and protection of the scenery of these areas is of high importance on the Forest.

Lands within view of scenic travel routes will be managed under Retention and Partial Retention visual management standards. Visual quality is considered as one of the most important resources to be protected under these land allocations. A total of 854,700 acres are allocated to Retention and Partial Retention Visual Quality Objectives to protect scenery. Of the 630,514 acres suitable for timber management, 364,150 acres will have Retention and Partial Retention Visual Quality Objectives to protect visual quality.

Unnatural landscape patterns will occur in some major viewsheds. These are Cooper Mountain to South Navarre, Shady Pass, Taneum/Manastash/Quartz Mountain, Little Naches, Cash Prairie, Little Rattlesnake, and South Fork Tieton. Landscape settings adjacent to some lakes will be altered by management activities. These are Antilon, McDaniel, and Bear Lakes.

A total of 266,364 acres of General Forest will be managed under Modification and Maximum Modification Visual Quality Objectives. The natural appearance of these lands as viewed from Forest roads would be altered to heavily altered.

Even though alteration of the natural appearance of these lands is permitted, visual management principles are to be applied.

These principles are contained in National Forest Landscape Management, Volumes 1 and 2. Published handbooks within The Visual Management System, include "Utilities", "Range", "Roads", "Timber", "Fire", "Recreation", and "Ski Areas". These handbooks are to be used in managing the visual resource.

Application of the visual management system in wilderness administration is necessary for maintenance of high quality scenery. Construction, rehabilitation, or reconstruction of trails or campsites require application of the Visual Absorption Capacity concept to protect and maintain scenic values.

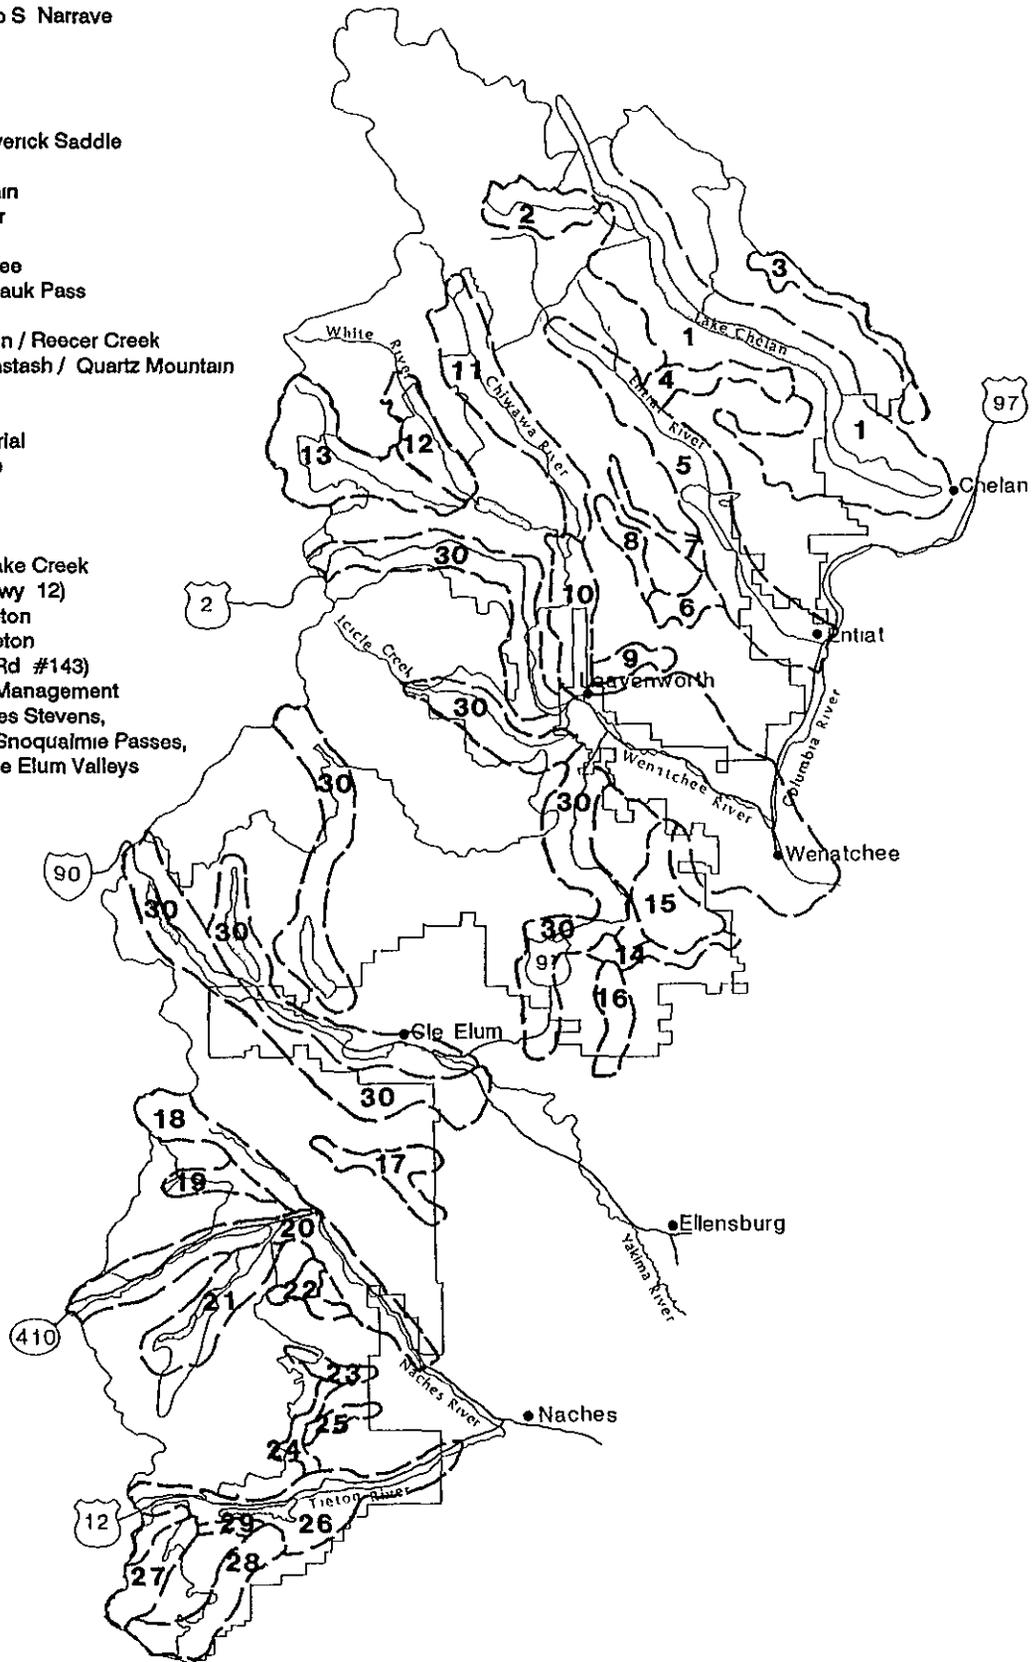

The visual management system is to be used in all resource programs to maintain high levels of scenic quality. Past applications of the system on the Forest have provided high quality end results when landscape architectural design concepts and visual management principles are applied during the Environmental Analysis stages of project design. Continued integration of visual concerns into project management is necessary to enhance and retain high visual quality. National Forest Landscape Management Handbooks are available as users guides in management of the visual resource and should be consulted. The Swauk and Entiat viewshed plans are available to provide further direction for management of the visual resource in those areas. Other viewshed plans are to be done during the next decade.

With the proper application of visual management direction set forth in the Management Prescriptions, Standards and Guidelines, and handbooks, the predicted visual appearance of inventoried viewsheds is as indicated on the following tables. A location map is also provided for their identification.

Monitoring will be conducted to ensure that the predicted conditions are being met.

5. WILDERNESS SETTING

The seven wilderness areas of the Forest, totaling 831,034 acres, provide a vast variety of recreation opportunities and possible experiences in a remote and wild recreation setting. The variety of settings and experiences possible are identified and categorized in the Wilderness Recreation Opportunity Spectrum System. All areas of each wilderness, except Alpine Lakes, are delineated into one of the four classes: *Pristine, Primitive, Semi-Primitive or Transition*. Each of these classes exhibit different physical, biological and social characteristics and managerial settings. Each have different levels of visitor use.

Pristine: The area is characterized as an extensive, unmodified natural environment. Natural processes and conditions have not been measurably affected by the influence of humans. Opportunities for solitude, isolation and challenge are high. Visitor use is very low. There are no managed trails in this class.

Primitive: The area is characterized by an essentially unmodified natural environment, with little influence of man noticeable in natural processes and conditions. The opportunities for solitude and isolation are high. Visitor use is low and density of managed trails is very low.

Semi-Primitive: The area is a predominantly unmodified natural environment. Evidence of man is noticeable in some areas. Opportunities for solitude and isolation are good. Trails and campsites are present. Visitor use is low but other users will generally be encountered during the primary use seasons.

Transition: The area is classified semi-primitive in most aspects of wilderness setting and resource conditions. Social encounters can be expected to be higher than semi-primitive during high use periods of the primary use season. Transition areas are close to major trail heads and areas that receive more of the single day use mixed in with users traveling into or out of the other classes.

The acreage in each Wilderness Recreation Opportunity Spectrum (WROS) class for all wilderness except Alpine Lakes is:

WROS class	Acres
Pristine	207,920
Primitive	248,820
Semi-Primitive	117,220
Transition	11,540

For more detailed information concerning Management for each WROS class see the Standards and Guidelines for Wilderness in this Chapter.

6. WILDLIFE

The objective of the wildlife program is to maintain and improve wildlife habitat with a program larger than any in the past. Growth is due to the demands for wildlife viewing and hunting, and the laws regarding threatened and endangered species and viable populations. The wildlife program is anticipated to expand to achieve the following:

1. Thirty percent or more of the program will be support to other resource activities. This support will be in the form of coordination with other management activities in order to avoid or mitigate adverse effects and identify opportunities to improve wildlife habitat. Support will be mostly to timber and recreation with a small percent spent on land exchanges and mining activities. There is planned development of combined wildlife/recreation projects for nonconsumptive use of wildlife.
2. Thirty percent or more of the program will be the development and maintenance programs and partnerships. Emphasis will be placed on maintaining and developing partnerships with the Yakama Indian Nation and the Confederated Tribes of Colville, Washington Department of Wildlife, U.S. Fish and Wildlife Service, timber organizations and State and local environmental groups to meet public demands for wildlife.
3. Monitoring programs will be developed to make up at least ten percent of the workload.

4. The 1,900 acres of nonstructural and 400 structural habitat improvements planned per year is anticipated to become thirty percent of the wildlife program. This activity will emphasize habitat improvements for Threatened, Endangered and Sensitive wildlife species to maintain viable populations. Second in priority to the T.E. and S. wildlife are improvements to increase recreation use of wildlife.

7. OLD GROWTH

The primary old growth forest habitat objective is to conserve enough old growth forest with adequate distribution to provide for biological diversity, wildlife and plant habitat and aesthetic values. It is the goal of this plan that old growth ecosystems and their attendant attributes be maintained to meet the needs and desires of the public. At the end of the first decade it is estimated that there will be 307,300 acres of old growth remaining and by the end of the fifth decade 261,200 acres (assuming no ingrowth).

To achieve these goals and objectives will require a better understanding of what old growth ecosystems really are--how do you define them. Once a definition can be agreed upon, an inventory of old growth will tell us how much we really have and the rate at which that amount is changing by type of site. In a word, old growth will need to be monitored. This will include monitoring of activities to determine if the Standards and Guidelines and Management Prescriptions are being implemented, and if when implemented, are meeting management objectives. Monitoring will also provide feedback for corrective actions.

To meet old growth management objectives will require cooperation both in and out of the Forest Service. Management partnerships between state, federal and private parties will be needed to facilitate the accomplishment of the goals and objectives for old growth management on the Wenatchee National Forest. Coordination with other resource management activities are needed to identify and avoid adverse impacts to old growth areas within harvest prescriptions that are needed within each sub-drainage to maintain adequate distribution of old growth for biological diversity and wildlife and plant habitat.

8. FISHERIES

The primary fish habitat management objectives are to maintain and improve fish habitat capability, develop an aggressive habitat management program, integrate fish and riparian habitat management into the other multiple-use activities and to develop management partnerships with State and Federal fish management agencies, the Yakima Indian Nation, the Confederated Tribes of Colville and private groups. It is the goal of this plan that fish habitat, quantity and quality, be at least maintained at existing levels and both the availability and quality of habitat should show an increasing trend.

Fish habitat goals and objectives will be accomplished through:

1. Coordination with other resource management activities in order to identify and avoid or mitigate potential adverse impacts and identify opportunities to improve fish habitat;
2. Implementation of a coordinated fish habitat and watershed improvement program based on inventories and drainage management objectives. It is anticipated that approximately four miles of anadromous fish stream would be treated each year;
3. Implementation of all activities using Forest-wide Standards and Guidelines, Best Management Practices and the Riparian Habitat Management Prescription (EW-2) to protect water quality and fish habitat;
4. Monitoring of activities to determine if the Standards and Guidelines and Management prescriptions being implemented are meeting management objectives and to provide feedback for corrective actions;
5. Implementation of an accelerated stream/watershed survey program to quantify current habitat conditions and develop management objectives by drainage. It is anticipated that approximately 250 miles of stream will be surveyed every year for the first few years;

6. Development of Five Year Action Plans, to be updated annually, to prioritize work and establish program direction; and

7. Development of management partnerships with State and other Federal fish, water quality, and environmental agencies, the Yakima Indian Nation, the Confederated Tribes of Colville, and private groups to facilitate the accomplishment of the above goal and objectives.

A major emphasis in the early stages of Plan implementation will be to determine the current condition of riparian habitat and to more fully develop desired riparian habitat conditions by sub-drainage.

Other objectives and specific outputs associated with riparian areas are incorporated in the discussions for related resources in this section of the Plan.

9. RIPARIAN AREAS

The primary objective for riparian areas will be to maintain and enhance long-term productivity to provide for riparian dependent resources including water quality, fish, wildlife and plant habitat. Decisions regarding management of other resource elements such as timber, grazing and recreation will be made in favor of riparian dependent resources where use conflicts exist.

10A. VEGETATION: TIMBER

Suitability

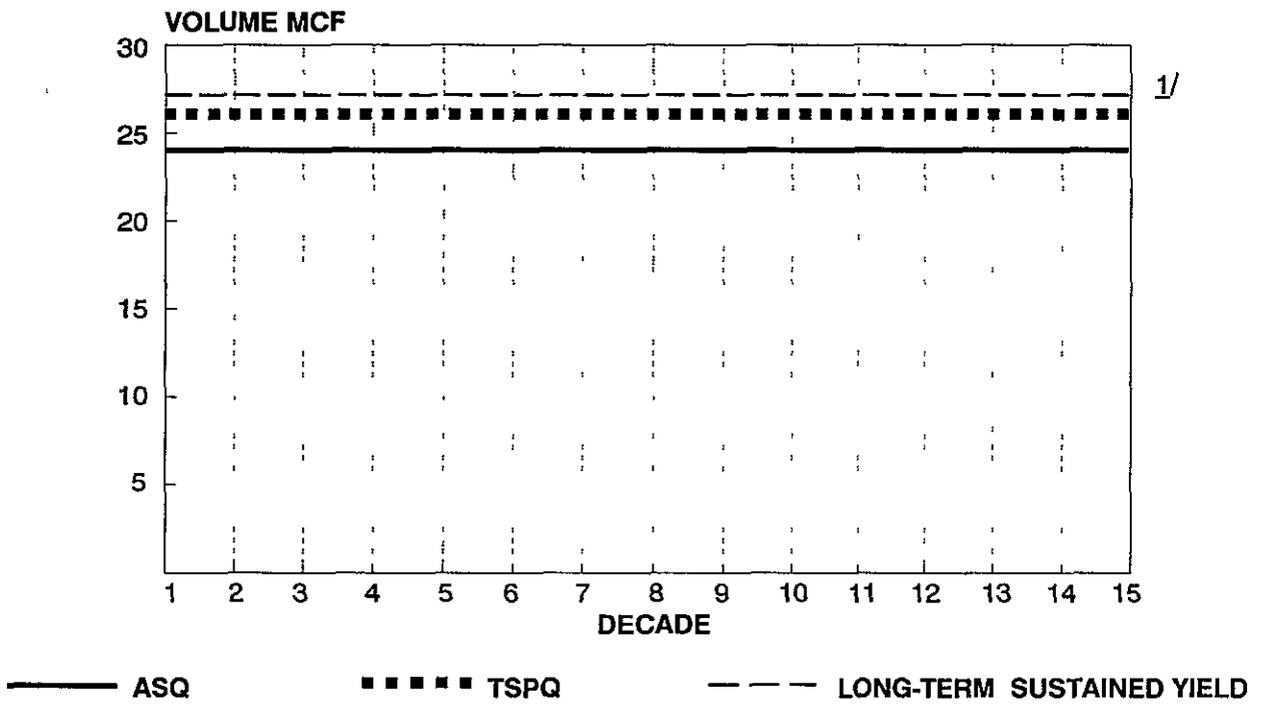

Timber harvest is scheduled from a base of 630,494 acres of suitable Forest lands. Table IV-5 shows a summary of the Forest land classification.

**TABLE IV-5
LAND CLASSIFICATION**

Classification	Acres
1. Non-Forest land (includes water, roads, and administrative sites)	713,082
2. Forest land	1,451,098
3. Forest land withdrawn from timber production	436,829
4. Forest land not capable of producing crops of industrial wood (not restockable within 5 years and less than 20 cu. ft. production)	137,717
5. Forest land physically unsuitable: --irreversible damage likely to occur	18,720
--not restockable but greater than 20 cu. ft production	65,933
6. Forest land--inadequate information	-0-
7. Tentatively suitable Forest land (item 2 minus items 3, 4, 5, and 6)	791,899
8. Forest land not appropriate for timber production	161,405
9. Unsuitable Forest land (items 3, 4, 5, and 8)	820,604
10. Total suitable Forest land ^{1/} (items 2 minus item 9)	630,494
11. Total National Forest land (items 1 and 2)	2,164,180

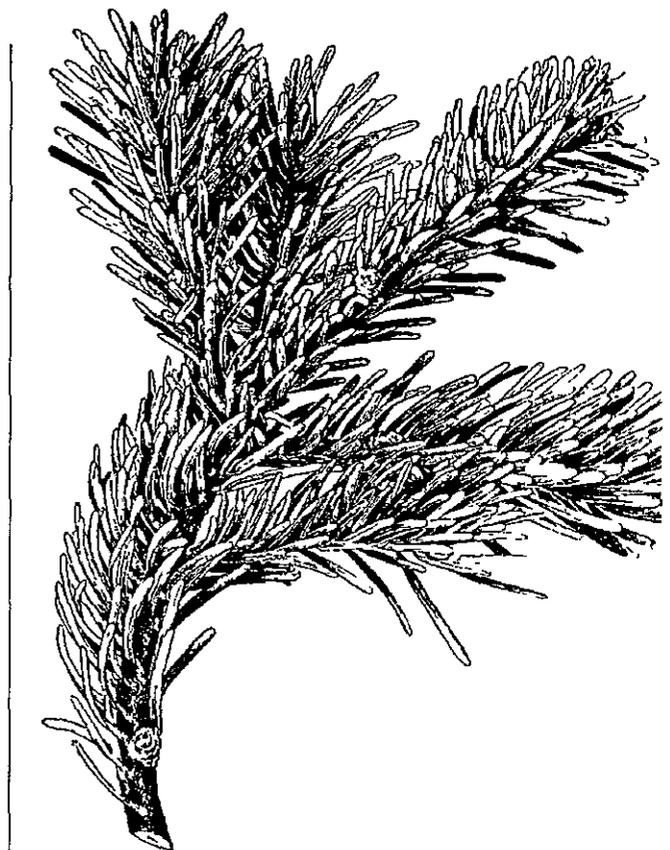

1/ The 630,494 acres are those available fo harvest in FORPLAN. Approximately 54,000 of these acres did not go into solution due to economic reasons

**FIGURE IV-2
PLANNED TIMBER SELL LEVELS**

1/ Planned sell level remains below potential harvest because wildlife trees are not included in sell but are included in long-term sustained yield.

Table IV-6 shows how the suitable land base is distributed by Management Area for this Plan. Scheduled timber harvest will come only from those allocations with suitable acres. All of the Management Area allocations with suitable lands will contribute to the ten year harvest program in the first decade.

**TABLE IV-6
SUITABLE ACRES BY MANAGEMENT AREA**

		Acres	
Management Area		Suitable	Unsuitable
EF-1	Experimental Forest ^{1/}	0	4,770
EW-1	Key Deer and Elk Habitat	47,700	71,042
EW-2	Riparian-Aquatic Habitat Protection Zone	33,963	13,399

^{1/} Some Harvest is expected in future years for experimental reasons. Any volume generated would be nonchargeable to the annual sale quantity.

^{2/} Nonscheduled harvests of danger trees and removals to manipulate the vegetation within recreation areas is expected. However, because this harvest is nonscheduled it is not chargeable to the annual sale quantity but is a part of the planned programmed harvest if financing is available.

^{3/} Some limited harvest for catastrophic damage or recreation improvements is possible, but is not expected to be significant or programmable.

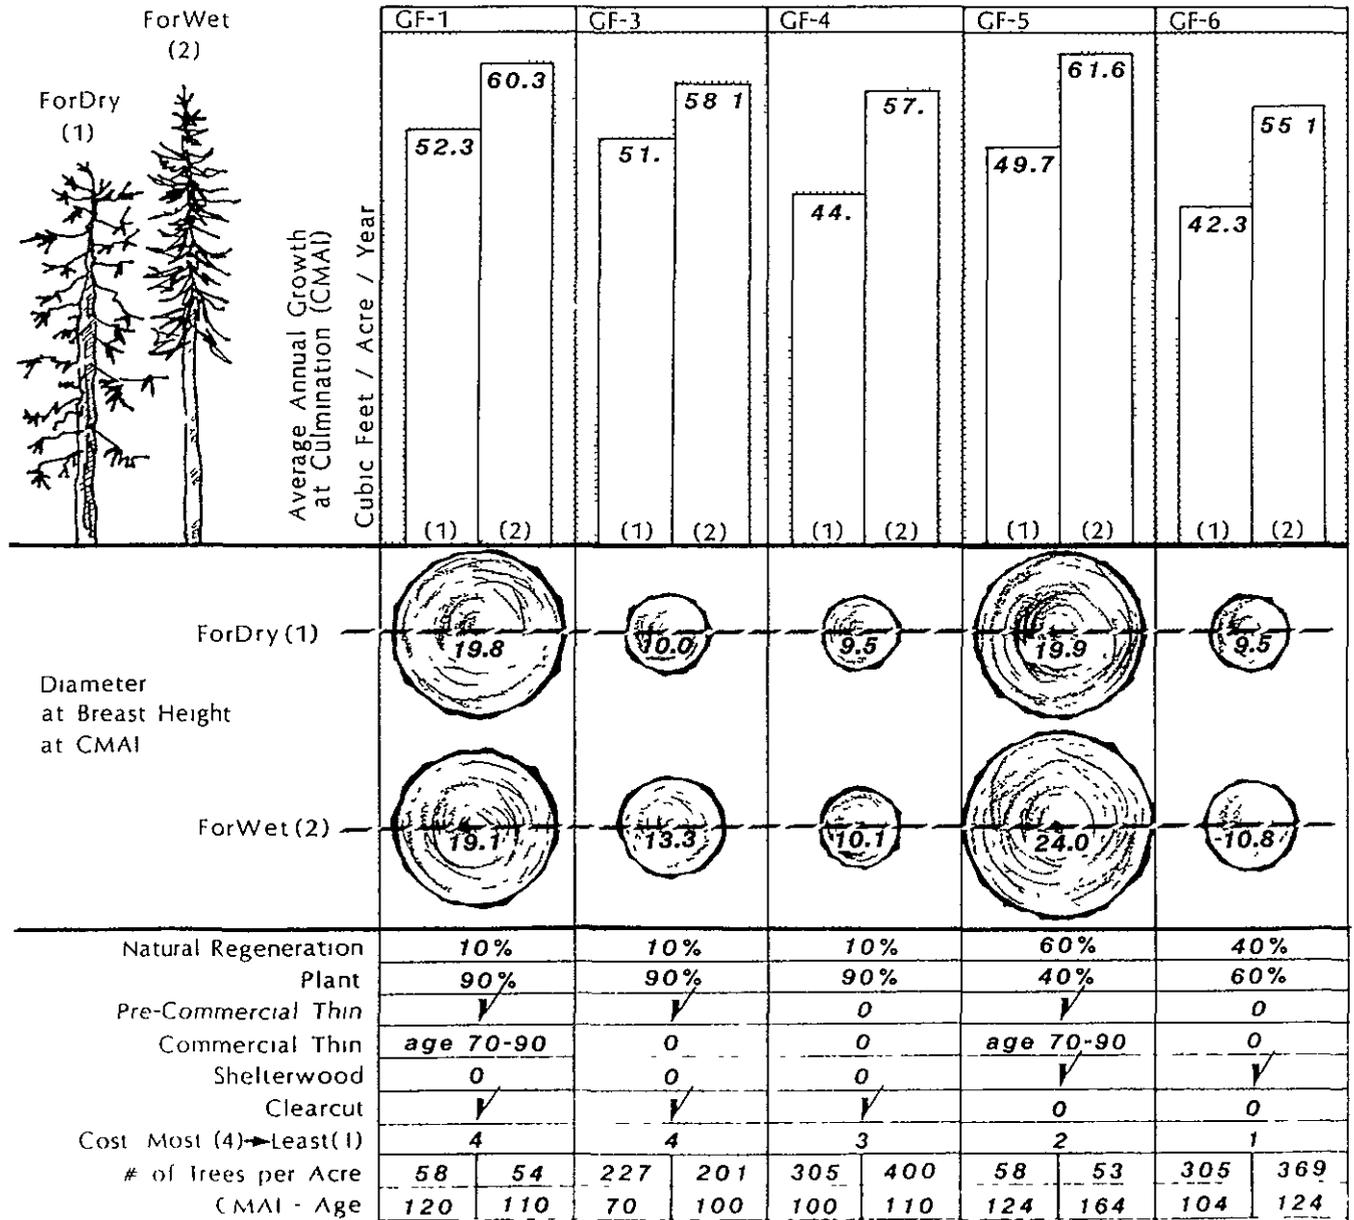

^{4/} Acres distributed among other management areas.

^{5/} Acres are also included in WI-1 wilderness management area, except 170 acres.

YIELD

Figure IV-3 depicts the General Forest Prescription timber regimes.

**FIGURE IV-3
TIMBER YIELD TABLES - GENERAL FOREST**

Management emphasis other than General Forest were restricted to silvicultural regimes designed to achieve specific resource objectives such as wildlife habitat or scenic viewsheds.

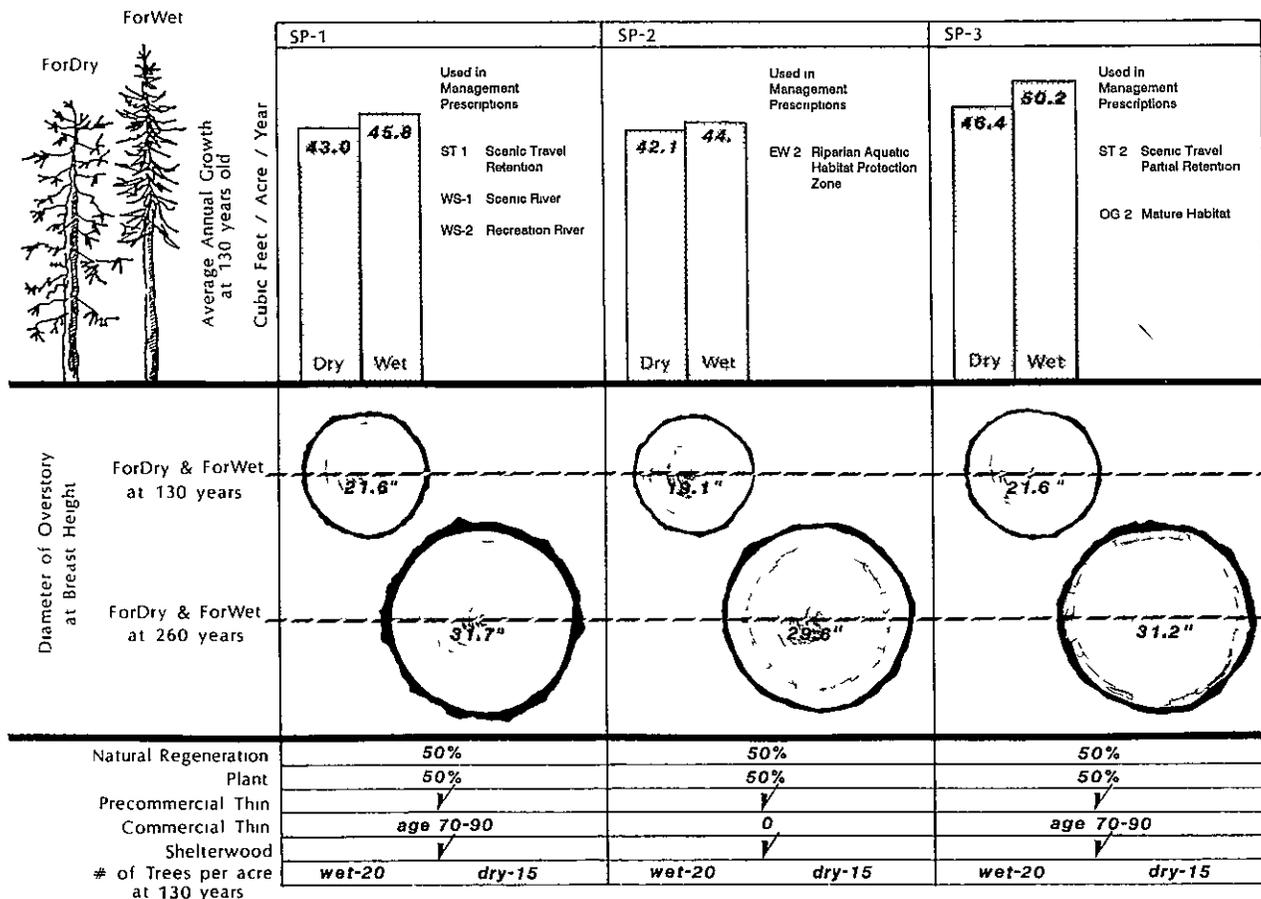

The intensive Range Management (RM-1) Prescription assumes the same silvicultural practices as GF-1, but with a 10 year regeneration lag. Three extended-rotation timber yield regimes were developed for use with the following prescriptions:

TABLE IV-7

Prescription	Yield Table
Key Big Game Habitat (EW-1)	RM-1
Riparian-Aquatic Habitat Protection Zone (EW-2)	SP-2
Mature Habitat (OG-2)	SP-3
Scenic Travel-Retention (ST-1)	SP-1
Scenic Travel-Partial Retention (ST-2)	SP-3
Scenic River (WS-1)	SP-1
Recreational River (WS-2)	SP-1
Dispersed Recreation, Unroaded, Timber Harvest (RE-4)	SP-2

Figure IV-4 depicts the extended-rotation timber yield regimes.

FIGURE IV-4
TIMBER YIELD TABLES - SPECIAL

Productivity

Most of the area not restockable within 5 years is within the less than 20 cubic foot productivity class. An approximation of timber productivity classification is shown in Table IV-8.

**TABLE IV-8
TIMBER PRODUCTIVITY CLASSIFICATION**

Potential Growth (Cubic Feet/Acre/Year)	Suitable Lands (Acres)
Less than 20	6,008
20-49	220,672
50-84	315,247
85-119	69,354
120-164	19,231
165-224	0
225+	0
Total	630,494

The average growth potential of trees measured during the 1977 inventory was site index 70 for ponderosa pine (dry ecotype) and site index 83 for Douglas-fir (wet ecotype). Site index is a measure of the height of trees at age 100 of the dominant or largest trees in the stands. This correlates to an average potential productivity of 52.3 cubic feet per acre per year on dry sites and 60.3 cubic feet per acre per year for wet types with intensive management.

Annual Sale Quantity

The annual sale quantity calculated from the suitable acres is 24.3 million cubic feet or 136 million board feet. In addition, there is 0.3 million cubic feet of sawtimber and 1.5 million cubic feet of other products. The sawtimber will come from unregulated acres including campgrounds, Experimental Forest, Mather Memorial Parkway, and/or salvage cutting from unsuitable lands. The other products are expected to be removed from down, defective, or trees too small to be included in the allowable sale quantity. See Table IV-9.

There is an estimated 54,000 acres of economically unsuitable lands that could become suitable if economic conditions and demand for forest products change the stumpage values. These are now handled as economically inefficient lands within the harvest prescriptions by the FORPLAN model. It is estimated that this could increase the annual allowable sale quantity by approximately 10 million board feet. This increase would be the maximum if all currently inefficient acres became economic. It is not likely that all currently inefficient acres would become suitable at the same time. It is reasonable to expect that there will always be some acres which are biologically suitable but not economic. Site specific evaluation may find somewhat more or less than the current estimate.

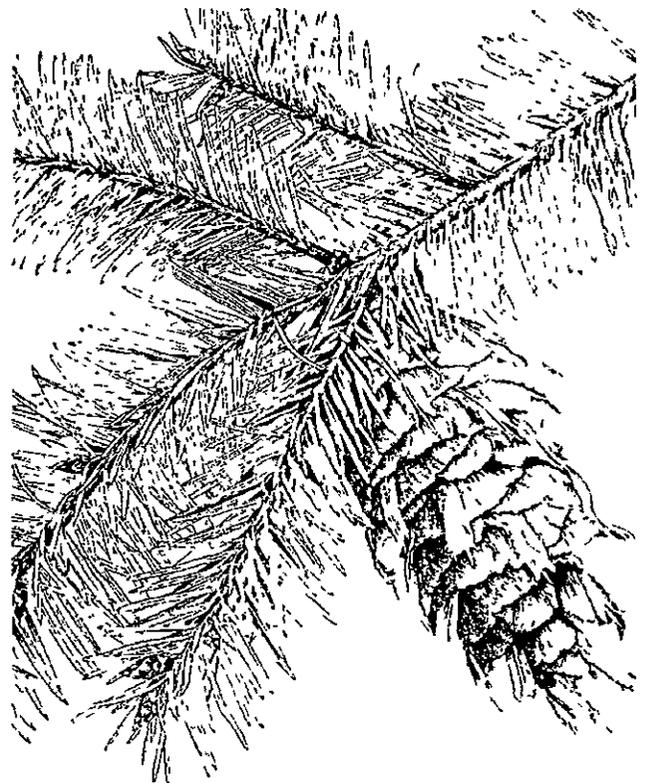

Table IV-9
Allowable Sale Quantity and Timber Sale Program Quantity
(Annual Average for First Decade) 1/

Allowable Sale Quantity <u>2/</u>		
Harvest Method	Sawtimber (MMCF)	Other Products (MMCF)
Regeneration harvest:		
Clearcut	11.8	1.1

Commercial Thinning	252
Salvage/Sanitation	210
Timber Stand Improvement	4,200 1/
Reforestation	4,300 2/

1/ Based on 10 year Action Plan.

2/ Based on reforestation/timber stand improvement needs report.

Table IV-11 shows all planned methods of timber harvest from clearcut to light volume removal, thinning and sanitation salvage.

Although all harvest methods can apply to all site conditions and management prescriptions, some combinations are more likely to occur than others. A little more than half of the volume harvested on the forest in the next decade will come from clearcutting, see Table IV-11. The remainder of the harvest volume will come from silvicultural prescriptions that leave various amounts of trees on the site.

The various stages of shelterwood cutting: preparatory cut, seed cut, and removal cut, occur on the greatest number of acres, totalling 5,229 acres per year. As these treatments can occur at different time frames on a given stand, each step is shown separately on Table IV-11.

Selection harvest systems will be used especially on the driest and highest elevation suitable sites. Ponderosa pine stands on south slopes, especially if free of mistletoe are especially adaptable to uneven-aged management. This is due to the

characteristics of the species including: (1) wind firmness, (2) ability to respond to partial harvest with increased growth and, (3) resistance to fire and logging damage due to thick bark (USDA 271, Bulletin number 1965). At elevations above 5,000 feet, the selection harvest system may be appropriate, also this is especially true in stands where natural regeneration of species such as Pacific silver fir is occurring.

Mid-elevation stands on north and west facing slopes containing grand fir and/or mistletoed Douglas-fir are commonly clearcut. Grand fir and Douglas-fir are highly susceptible to Phellinus weirrii a root rot, and defoliating insects such as western spruce budworm and the tussock moth. Attempts at uneven-aged management and partial cutting tends to favor increased disease and insect losses in these particular species types. Currently, heavy mortality is occurring in old partial cut and overstocked grand fir stands due to Scolytus ventralis, a bark beetle that prefers grand fir. Past spruce budworm treatment areas were primarily located on grand fir and Douglas-fir sites. As much as 200,000 acres were defoliated by the budworm on the forest between 1970 and 1978

Clearcutting, although effective in alleviating many of the current insect, disease, and fuel buildups, is not acceptable to much of the public unless the clearcuts are very carefully designed. Therefore, a shelterwood system designed to maintain large, older trees of the most desirable species and vigor will be used on the foreground of most scenic travel ways. Also see Appendix H of the FEIS for a detailed discussion of the selection of harvest cutting methods.

10 B. VEGETATION: FORAGE

In the first decade permitted livestock grazing (Table IV-2) will average 23,000 AUM's which is the same as the current use, and leaves a livestock grazing capacity of approximately 15,700 AUM's unused. In addition to the excess livestock capacity, the Forest's total forage production allows for approximately 94,700 AUM's of forage for big game. Actual permitted use for livestock will not exceed the production potential on existing allotments and will allow for expected increases in big game numbers.

Existing range allotments have an estimated livestock grazing capacity of over 27,000 AUM's, on 203,500 acres of suitable range, and will accommodate all of the expected increase in permitted use. However, many of the existing allotment plans are outdated, and in order to meet the potential outputs these plans require reanalysis. It is through full implementation of these reanalyzed plans that livestock numbers will be increased, and that other outputs such as improved range conditions and enhancement of other resource will be attained. A schedule of allotment analysis needs can be found in Appendix A under range management detailed project schedules.

Although the existing allotments may carry the expected livestock increase in the first and second decades, some areas outside of these allotments containing suitable range may be incorporated into the allotments in order to meet all resource objectives. Some of the existing sheep allotments may be converted to cattle allotments if current trends in the livestock industry continue.

As discussed above, meeting the goals and objectives of this Plan is contingent on full implementation of the allotment plans. These allotment plans contain schedules for structural improvements such as fences and water developments, and non-structural improvements such as noxious weed control. In order to fully implement allotment plans, accomplishment of improvement schedules become imperative. Table IV-2 show outputs of 9 miles of fence, 11-12 spring developments, and about 375 acres of noxious weed control which will be required annually to fully implement the forage management program. Approximately one-half of these are reconstruction of existing improvements while the remainder are needed to implement existing plans. Detailed project schedules are found in Appendix A and show type, location, amount, and year scheduled. This detailed schedule will be updated periodically to reflect changes resulting from reanalysis of allotments.

The final step in meeting the objectives of this Plan is monitoring the forage management program. The monitoring requirements are found in Table V-1 in Chapter V.

10 C. VEGETATION: UNIQUE ECOSYSTEMS

The Tumwater Botanical Area was established under Regulation T-9(I) on June 10, 1938, for the protection of Lewisia tweedyi. The 1,104 acres were redesignated in 1971 as a botanical area under 36 CFR 251.22 to be managed in a near natural condition to protect plant species which occur there.

Although the area is located along a major highway, it is rather inaccessible due to the steep, rugged terrain. It is usually visited only by people who wish to view or study Lewisia tweedyi. The area is within Sections 28 and 34, T.25N., R17E., P.M.W., and is approximately four miles north of Leavenworth, Washington, in the Tumwater Canyon.

One additional Botanical Area (Lake Creek) is proposed by this Plan.

Lake Creek Botanical Area - Located on the Entiat Ranger District in Sections 27, 28, 33, and 34, T. 29 N., R. 19 E., this area is 212 acres. Protection is proposed for plants associated with an undisturbed wetland habitat.

Several additional unique areas are included in this Plan as special interest (SI-2) allocations. They include the following: The west end of Lake Wenatchee allocated for its aquatic habitat, Twin Lakes Ponds; Wenatchee River Indian Site for its cultural sites; a special botanical area near Ponderosa Estates; Upper Naneum Meadow for its ecosystem; Boulder Cave, Kloochman Rock, Goose Egg Mountain, and Blue Slide for geological as well as botanical features.

The Plan also includes old growth preserved for wildlife habitat, ecosystems diversity, and aesthetic reasons in addition to the spotted owl network. These areas include Hornet Ridge, Rattlesnake Springs, Heather Lake Trailhead, upper end of the Little Wenatchee River, and the "Sanctuary" cedar grove.

10 D. VEGETATION: THREATENED, ENDANGERED, AND SENSITIVE PLANTS

There are no known Federally listed threatened or endangered plant species on the Forest.

There are 50 plant species on the Forest that are on the Region 6 sensitive plant list (Table IV-12). Of the 50 species, 7 are candidates for the Federal list and the remaining 43 are listed by the State of Washington. The extent of the populations of these species on the Forest is unknown.

Before a project is initiated, inventories for populations and distribution of threatened, endangered, and sensitive species will be conducted on a priority basis. Some general inventories of species and their habitat will be required and research completed as needed to meet management goals.

Key to Abbreviations Used Above

Federal Candidate Species

- Cat. 1 = Category 1 Species (US Fish and Wildlife Service has enough information to support the appropriateness of proposing the species to the list of Endangered or Threatened species)
- Cat. 2 = Category 2 Species (Needs further information to confirm the appropriateness of proposing the species to the list of Endangered or Threatened species)
- Cat. 3 = Category 3 Species (No longer being considered for listing as Endangered or Threatened and are not regarded as candidate species:
 - a. Taxon extinct
 - b. Not a taxonomic entity
 - c. Taxon more abundant and/or widespread than previously thought and/or not subject to any identifiable threat)

RF - S = Regional Forester Sensitive Species

D = Documented occurrence

S = Suspected occurrence

10 E. VEGETATION: RESEARCH NATURAL AREAS

Research Natural Areas (RNA's) are part of a Federal system of tracts established for non-manipulative research and educational purposes. Each RNA is a site where some features are preserved for scientific purposes and natural processes are allowed to dominate. Their main purposes are to provide: (1) baseline areas against which effects of human activities can be measured; (2) sites for study of natural processes in undisturbed ecosystems; and (3) gene pool preserves for all types of organisms, especially those which are classified as rare and endangered.

Prior to establishment, a comprehensive formal report is made. For RNA's proposed on National Forest System lands, the report is submitted to the Chief of the Forest Service for approval.

a. Established RNA's

There are two established RNA's on the Forest. Meeks Table RNA on the Naches Ranger District is 64 acres and represents the ponderosa pine/pine grass plant community with a co-dominance of Douglas-fir. It was established on July 7, 1948, and is now within the William O. Douglas Wilderness.

Thompson Clover RNA located in Swakane Canyon on the Entiat Ranger District exemplifies a plant community characterized by Thompson Clover. It was established on February 17, 1977.

b. Formally Proposed RNA's

The Research Natural Area Committee for the Pacific Northwest has formally proposed two additional RNA's. Eldorado Creek located in the Teanaway drainage of the Cle Elum Ranger District is 1,336 acres in size and represents a plant community found on serpentine derived soils. The Eldorado Creek area was designated as a Special Area (Proposed RNA) in the Alpine Lakes Management Plan (November 2, 1981). Fish Lake Bog on the Lake Wenatchee Ranger

District is a 106 acre area on the west end of Fish Lake near Lake Wenatchee. This represents a floating bog community.

Preliminary reports have been made for both of these areas; Fish Lake Bog on July 5, 1979, and Eldorado Creek on August 9, 1972. A supplemental report on the mineral character of the proposed Eldorado Creek RNA was made on November 6, 1974.

c. Recommended RNA's

The Research Natural Area Committee for the Pacific Northwest Region determined that the candidate RNA's listed in Table IV-13 represent the best examples of particular kinds of natural ecosystems in the Region and are needed to meet present and future demands. There may be some future RNA needs that can best be satisfied on the Wenatchee National Forest. When suitable new areas are identified, they will be considered for addition to the Research Natural Area inventory.

TABLE IV-13
RECOMMENDED RESEARCH NATURAL AREAS
1984

Name	Area (Acres)	Location (District)	Plant Community Exemplified
• 1 Cedar Creek	2205	Naches	Mixed old-growth conifer/ shrub forest and Pacific silver fir forest
** 2 Icicle/Frosty Creek	784	Leavenworth	Western red cedar/western hemlock forest
** 3 Chiwaukum Creek	1124	Leavenworth	Grand fir mixed old-growth conifer/shrub
4 Drop Creek	530	Cle Elum	Englemann Spruce/Subal- pine fir forest

* Within the William O. Douglas Wilderness

** Within Alpine Lakes Wilderness

10 F. VEGETATION: ENTIAT EXPERIMENTAL FOREST

a. Current Management Program

The Entiat Experimental Forest includes 4,770 acres of Forest lands located within the Entiat River drainage northwest of Wenatchee, Washington. Research has been conducted on the area since 1957; in 1971, it was formally designated as an Experimental Forest. The Pacific Northwest Forest and Range Experiment Station and the Wenatchee National Forest cooperatively administer the area with the primary goal of providing opportunities for studying the effects of forest management and fire on vegetation, soil, and water resources. The area was selected as being representative of steep, forested watersheds occurring along the east slope of the Cascades. It consists of three similar, contiguous watersheds ranging in size from 1,168 acres to 1,393 acres, and in elevation from 1,800 feet to 7,000 feet. The mean slope is 50 percent with slopes as steep as 90 percent.

A major wildfire which burned most of the area in 1970 has had a dramatic impact on Forest vegetation. Pre-fire vegetation was primarily undisturbed, mature forest with small, subalpine grass-forb openings and bare rock. About 75 percent of the Forest was classed as ponderosa pine, with Douglas-fir the main associated species. Thickets of dense lodgepole pine occurred on wetter sites at higher elevations. Important understory species included bitterbrush, snowbrush, ceanothus, pinegrass, and numerous forbs. Fifteen years after the fire, the vegetation consists of a mosaic of shrub fields intermixed with planted pine and fir, and dense, young stands of naturally-established lodgepole pine. Scattered remnants of unburned old-growth forest occur on rocky ridges and outcrops.

The original research plan for the experimental watersheds was to develop baseline information on climate and hydrology under natural conditions, then test for changes following the construction of roads and implementation of several timber harvest practices. The collection of this information and the preparation of harvest plans were nearly complete when the watersheds burned.

Fire is a common occurrence on this Forest; hence research objectives were quickly changed to utilize the preburn data to evaluate effects of fire on the environment and the alteration of those effects by the re-establishment of forest vegetation. Initial post-fire studies provided land managers, resource specialists, and scientists with a better understanding of: the hydrologic response of burned watersheds including water yield and physical water quality; chemical water quality and site productivity in response to wildfire and erosion control fertilization; natural vegetation recovery and the effectiveness of erosion control seeding and fertilization treatments; soil and water responses to several methods of timber salvage; and effects of a large wildfire on local and regional economics.

11. WATER

The goal for water resource management under this Plan is to maintain favorable conditions of streamflow in regards to water quality, quantity and timing of flows. The dominant objective will be to insure meeting or exceeding Federal and Washington State water quality standards during implementation of this Plan. Accomplishment of the goal will be achieved through a number of objectives that emphasize maintenance or improvement of watershed condition.

Existing data indicate that most streams on the Forest exceed Washington State water quality standards. Water quality will meet the Washington State Class AA (excellent) standards in all decades of the Plan. This will require numerous actions including increased technical support in management decisions, improved resource inventories, application and continuous improvement of best management practices, improvements in riparian area management, aggressive watershed and fish habitat improvement programs, and increased coordination of management activities with other landowners and management entities.

Land management activities must be planned and conducted in a manner so that watershed conditions provide for the protection of the beneficial uses of water. Technical support for water resources will be provided at a level of detail

sufficient to facilitate sound management decisions that minimize the potential for damage to watershed resources, while meeting other multiple-use objectives. Coordinated resource management planning will be promoted, especially in watersheds in which resources are at risk.

Water resource inventory and monitoring will be conducted, in cooperation with other resources and management entities. Inventory will provide information on watershed condition needed for the development of management objectives by sub-drainage. Monitoring will provide feedback for determining if the practices and prescriptions being implemented are meeting management objectives and for identifying corrective action.

The watershed improvement program will be aimed at eliminating the backlog of improvement projects and assuring that project maintenance and treatment of newly identified needs occurs in a timely manner. Improvement projects will be completed in cooperation with other resources and management entities. Refer to Table IV-2 for an estimate of the number of acres treated by decade under this Plan.

The water rights program will be directed at obtaining water rights for all on-Forest water uses. Water uses on National Forest System lands will be protected.

The development of cooperative relationships with State and other Federal agencies, the Yakima Indian Nation, the Confederated Tribes of Colville, and private groups will facilitate the accomplishment of the above goals and objectives.

Coordination of these activities will be facilitated through a Five Year Action Plan designed to provide program direction, in cooperation with the soil resource program.

12. SOIL

The goal for the soils program under this Plan is to maintain or enhance the productive properties of the soil resource. This basic goal will be achieved by following Forest-wide Standards and Guidelines for the analysis and implementation of projects in a manner designed to protect soil productivity.

A primary component of the soils program will be to provide technical support to other resource activities at a level of detail sufficient to make management decisions that minimize the potential for damage to the soil resource. It is readily apparent that negative soil impacts (i.e. compaction, displacement, erosion, puddling, etc.) can occur within a very short period of time. However, soil building processes occur very slowly over long periods of time. Soil rehabilitation efforts seldom restore soils to their original condition; therefore, it is better to avoid, wherever possible, management practices that have a negative impact on the soil resources. In many cases, minimizing the amount of land affected by a given management activity, may be the only option available.

Another major emphasis for the soil program will be the completion and update of the Forest Soil Resource Inventory Program and the development of GIS capabilities. By 1992, remapping of the Wenatchee National Forest to the National Cooperative Soil Survey (NCSS) standards for Order II and Order III levels of intensity will be accomplished with the completion of the Naches area survey. The Order II level was used for all NF lands outside of wilderness areas, and the Order III level was used for the less intensively managed lands inside the wilderness areas. Kittitas County soil survey was completed in 1980 under a cooperative agreement with the State of Washington and the Soil Conservation Service. That survey was known as a "land grading soil survey", primarily designed to establish values of private forest lands in the State of Washington. Chelan County was mapped under the Cashmere Mountain cooperative agreement between the SCS, Washington State University, and the Forest Service. This soil survey was completed in May, 1989.

Soil survey maps and the accompanying interpretative information will be an important data layer for the GIS system, because the use and management of many other resources are often affected by soil characteristics. Emphasis will be placed on the input of this information into the GIS system as soon as it becomes available.

Another major component of the soils program will be Forest and project-level monitoring, conducted in cooperation with other resource and management entities. Monitoring will provide feedback for determining if the projects and practices being implemented are meeting management objectives and for identifying corrective action.

The Forest-wide watershed improvement inventory will be reviewed and revised by the end of the 1990 field season. The review and update of this inventory will be done on a district basis. Forest priorities will be re-established and the implementation schedule will be revised. Each district will be responsible for the development and update of rehabilitation plans so that work can be accomplished efficiently as funds become available.

The development of cooperative relationships with State and other Federal agencies, the Yakima Indian Nation, the Confederated Tribes of Colville, and private groups will facilitate the accomplishment of the above goals and objectives. This will be especially important in regards to coordinated resource management planning in watersheds in which resources are at risk.

Coordination of these activities will be facilitated through a Five Year Action Plan designed to provide program direction, in cooperation with the water resource program.

13. MINERALS

Because of the nature of the mining and mineral leasing laws, the management of mineral resource activities will continue to be largely reactive in nature. As a consequence, predicting the level of mineral resource activity, outputs and funding levels is difficult. However, some activity levels have been estimated and are shown on Table IV-2, and mineral program funding will be used to accommodate at least that level of activities. This will include but not be limited to; the processing of 35 to 100 leases and permits per year, the processing of and monitoring of 100 to 180 notices of intent and/or plans of operation, and the geologic evaluations needed to accommodate the timber sale programs. As the local, regional and National demand for mineral resources increases, however, it is expected that the mineral related activity conducted on this Forest will also increase. It is also assumed that increased activity will probably accompany any new developments industry makes in exploration, mining or mineral processing technology, or when new information is acquired which indicates that the Forest has a potential for the occurrence of previously unknown mineral resources. If this happens the mineral management funding will have to increase to accommodate the increased activities.

Under this plan, the area withdrawn as Wilderness will not change, and only 2,547 acres (less than 1 percent of the total Forest area) will be proposed as new withdrawals. The only mineral activity that will occur within the withdrawn areas will be limited to that conducted under rights which are confirmed to have existed prior to the date of withdrawal. It is assumed that activity will be relatively negligible. Of the remaining Forest area in which mineral activities will be generally encouraged and facilitated, twenty percent (436,915 acres) will be managed as highly sensitive areas (e.g., experimental forest, old growth dependent species habitat, developed recreation sites, dispersed recreation areas, special areas or as Wild and Scenic rivers), and the remaining will be managed under relatively unrestrictive management direction.

Since the Forest has little influence on the demand for mineral resources and little to do with the technological factors associated with the mining industry, it will have very little actual influence on the amount of activity that is conducted on the Forest. It is assumed that withdrawals and highly restrictive management prescriptions will have some effect on the type of activity that is actually conducted, but predicting what that effect will be is difficult (see Chapter IV of the FEIS). However, using available demand information and past activity as a basis, mineral resource activity and production estimates have been made and are shown on Table IV-2. As this table indicates, the energy mineral related workload will be dominated by the processing of lease applications and the processing of prospecting, exploration and development proposals. Based primarily on past leasing activity and demand projections provided by Donald A. Hull (November 30, 1982), the number of these types of actions is estimated to be about 35 increasing to possibly 60 during the last decade; and that activity may be accompanied by the production from 104 billion BTU's of energy in the first decade to 607 BTU's in the last decade.

Since little information concerning the energy mineral resources of the Forest is available, it is difficult to predict exactly where the activity will occur. However it is assumed that this activity will concentrate primarily on the Naches, Cle Elum and Leavenworth Ranger Districts. It will be dominated by interest in oil and gas resource exploration and development. However, should the energy situation return to that of the 70's, that return could be accompanied by an increased interest in the geothermal and coal resources of the Forest.

As with the energy mineral related activity, the non-energy locatable mineral related workload has been estimated using past activity and anticipated increases in the demand for both precious and base metal resources. This workload will consist of processing notices of intent and plans of operations for proposed prospecting, exploration and development activities, and will also include the conducting of mineral evaluations needed to respond to patent applications, conflicts between mineral resource development and other resource uses, or to proposed land disposal actions. It

appears that most interest will focus on the precious metals (e.g. gold and silver) and possibly on some industrial mineral commodities (e.g., limestone, industrial-grade garnet deposits and some building stone deposits). However, an increase in base metal prices could renew interest in those commodities as well. Estimates of the volume or value of these mineral commodities have not been made.

The demand for common variety mineral resources, especially those associated with Forest road construction activity, is expected to decrease somewhat. However, there may be some increase in the demand for these resources by private industry as is indicated on Table IV-2. This private demand will be primarily for highway construction, building or landscape purposes. However, as with locatable mineral commodities, predicting the future demand for these minerals is very difficult.

14. LANDS

Existing utility corridors will be continued. Capacity would be increased to the degree feasible to accommodate increased energy needs (i.e., 115 KV line might be increased to 230 KV). One potential new corridor is identified. This corridor would utilize a "window" in the Sheets Pass to Pyramid Peak area and then run southeasterly toward Hanford and the Tri-Cities area.

For this Plan, it is estimated that the number of small hydroelectric proposals would be about 25. Three or four of these could be expected to reach the application for license stage.

Landownership guidance is provided in each management prescription. Overall priorities for landownership adjustments are: (1) those that make possible improved resource management, and (2) those that increase management efficiency and reduce management costs.

A landownership classification plan based on the guidance in the prescriptions may be found in the Plan Appendix B.

Additional guidance is to be found in the Chelan, Lake Wenatchee, and Icicle Composite Plans.

15. ROADS

The overall road management and development programs necessary to implement this alternative are as follows.

a. Management

The road management strategy in this plan is to reduce the cost and impact of roads, to provide road access to developed sites to a service level comparable with their development level, to correct chronic sediment sources and prevent fish barriers, to maintain the current pattern of dispersed recreation, and to not improve access to wilderness areas to the extent that wilderness values are reduced. In order to implement this plan, the following has been done.

1. The proposed management for all existing Forest Development Roads is documented in the Forest Development Transportation Plan (FDTP). The FDTP includes elements for maintenance, service level, etc., for each individual road on the Forest. In addition, all known Forest roads are shown on primary base series maps at 1:24,000 scale. These maps and inventories, including the bridge inventory, and a map of the Forest Highway system comprise the Forest Development Transportation Plan (FDTP) that is referred to in NFMA.
2. A method for identifying the road management objectives for the new construction and reconstruction is found in FSH 7709. This process (resource elements-design criteria-design standards) is intended to ensure that all new roads are designed and operated to standards that are responsive to the resource objectives of this plan.
3. Table IV-14 identifies the proposed service levels for the arterial and collector system. A map of these service levels and road segments is available in the Supervisor's Office.

b. Development

The strategy for development will be to provide local roads as necessary for timber management and resource protection, to reconstruct the arterial and collector system to provide for safe joint use, and to minimize the total cost of operating the existing system by reducing the user and maintenance costs associated with high traffic volumes over gravel surfaced roads. Following, are the proposed levels of development.

1. Local Roads

Approximately 1,468 miles of new road are expected to result from the implementation of this Plan. Some 706 miles of this are in areas that are currently unroaded, but allocated to timber harvest prescriptions in this Plan. It is assumed that the majority of this construction will occur in the next 18 years. Most new roads will be closed after timber management activities unless there is an overriding need to keep them open.

2. Arterial/Collector Roads

The proposed construction and reconstruction of the arterial and collector system to meet the resource objectives of this plan are found on Table IV-14. It is estimated that 18 miles will be constructed, and 162 miles will be reconstructed at an average annual rate of 18 miles a year for the next 10 years.

3. Issue Roads

The Forest Service has no need of a road across Naches Pass for management purposes and has no plans to construct such a road. However, land allocations in the "pass area" do not preclude roading and the possibility exists that another government agency or private entity could propose a road through the pass, although, there are no proponents at present. Any road project proposal of this nature would be subject to the appropriate site-specific environmental analysis, including public involvement and proper documentation.

15. FACILITIES

The Facilities Master Plan identifies Forest facilities needs and sets priorities to construct or reconstruct buildings and utility systems in order to provide facilities which are safe, efficient, cost effective, and attractive. Due to the significant increase in permanent employees in the past 3 years, many of the existing administrative facilities on the Forest are not adequate to meet current needs. The most critical facilities needed currently and for the next 10 years include increased office space, adequate housing for temporary employees, and renovation of public contact areas.

E. FOREST-WIDE STANDARDS AND GUIDELINES

These Forest-wide Standards and Guidelines when used in conjunction with the management prescriptions for the management areas, state the bounds or constraints within which all practices will be carried out in achieving the planned objectives. They are intended to be used with national and regional policies, standards and guidelines contained in Forest Service manuals and handbooks, and the Pacific Northwest Regional Guide.

RECREATION

Recreation Planning and Inventory

1. Develop management plans for newly classified special areas.
2. Review Recreation Composite, Forest Trail and ORV Plans annually for adequacy, and update as needed.
3. Visual quality objectives shown represent *minimums, higher ones may be achieved.*
4. Mitigation measures to reduce the visual impacts upon the landscape will be considered and used to meet the visual quality objective.
5. Harvest units must be located and designed to blend with the natural landscape character to the extent practicable.
6. Evaluate the visual absorption capacity (a function of: slope, vegetative character, soil color contrast, productivity) and apply landscape architectural design arts principles in land form manipulation and vegetation management.
7. Landscape architectural concepts will be used to design and blend structural elements (buildings, fences, poles, utility lines, culverts, bridges, microwave towers, roads, trails, etc.) into the landscape to meet visual quality objectives.

8. Design roads, waterways, and trail systems to be consistent with adopted Recreation Opportunity Spectrum class and Visual Quality Objectives indicated by the management prescriptions.

9. Manage the setting of Forest openings such as meadows, lakes, ponds, and reservoirs in a manner to retain their natural appearing character.

10. Rehabilitation actions will be planned and scheduled in management areas where the existing visual condition does not meet the adopted visual quality objective.

11. Update the Forest Existing Visual Condition (EVC) and Visual Quality Objective (VQO) mapping every five years, in the Forest database or in a Geographic Information System (GIS).

12. Evaluate existing developed and dispersed recreation sites to determine if they meet present and future public expectations, needs, and desires, and if they have the resource capability of sustaining present or future levels of visitor use.

13. Recreation facility development or improvement planning will conform to and be consistent with the applicable ROS Class criteria for level and scale of development, setting, experience level, and social interaction.

14. Recreation site or dispersed area planning on a site specific or area basis will be done through the Environmental Analysis process in accordance with ROS Class criteria, visual quality objectives and other applicable management objectives.

15. Plan new developed and dispersed winter recreation opportunities in response to the growing demand for winter sports areas and developed facilities. Seek maximum opportunities for partnerships and joint ventures with private developers and other agencies in providing recreation development.

16. Complete area wide or composite recreation management plans for logical planning areas where:

- A. Conflicting uses and activities are creating Forest-level issues and controversies.
- B. Major construction or reconstruction of developed sites and facilities is necessary, and recreation uses and activities need to be coordinated.
- C. Multiple activities and use patterns have created highly complex situations needing careful detailed planning.

17. Evaluate selected scenic travel viewsheds for possible future nomination and/or designation as National Forest Scenic Byways.

18. Complete and maintain a cultural resource overview of the Forest. The overview should summarize all previously recorded cultural resource information for the Forest; provide a framework for evaluating cultural resources identified through the inventory process; develop a preliminary research design to guide future surveys, inventories, and scientific investigations; and identify opportunities for interpretation of a range of cultural properties.

19. Conduct cultural resource inventories (survey and site recordation) according to strategies and consultation procedures established on the Forest. Emphasis will be given to all areas where ground disturbing activities are planned, to ensure discovery of all reasonably locatable cultural resources. These inventories should be supervised by a cultural resource professional.

There are also substantial inventory needs on those Forest acres (such as wilderness) that are not affected by anticipated project activities. Priorities for non-project related inventory will be:

- A. Areas experiencing degradation through natural processes or intensive public use.
- B. Areas of reported but unverified sites.
- C. Areas where cultural resources are highly probable as determined by known land use patterns, terrain features, resource distributions, and the nature and extent of previous landscape modifications.

20. Develop management plans, in consultation with the Washington State Historic Preservation Office (SHPO), for all sites listed in the National Register of Historic Places. These plans should specify measures to protect and maintain the cultural integrity of the sites, objectives for management of the visual setting, levels and types of other resource uses compatible with the historic values of the sites, an interpretive design if so desired, and a program to carry out the objectives of the plan. Adaptive or compatible modern uses of historic properties, such as use as Forest Service administrative facilities or under special use permit with protective stipulations, should be encouraged.

Cultural Resources Evaluation and Assessment

1. Evaluate the significance of inventoried sites by applying the criteria for eligibility to the National Register of Historic places. Sites may be treated as individual properties, thematic groups, or historic districts. Efforts should be made to look at the local or regional context of the cultural resource and to determine the relationship of the property to others within the same historic context and/or specified geographic area. Give priority to those properties that may be affected by project activities. Develop a plan to evaluate all other cultural resources through cost effective means as the Forest-wide inventory nears completion.

2. Nominate cultural resources that meet the appropriate criteria for eligibility to the National Register of Historic Places. Nominations will be scheduled incidentally until completion of the Forest-wide inventory of cultural resources.

3. Consider the effects of all Forest Service undertakings on significant cultural resources, and assure the development of measures to avoid or mitigate any adverse effects.

Cultural Resource Protection and Enhancement

1. Develop measures, in consultation with the Washington State Historic Preservation Office (SHPO) and, if necessary, the Advisory Council on Historic Preservation (ACHP), to protect significant sites from adverse effects due to project activities. These measures may range from complete avoidance of the site and corresponding protection of its environmental setting, to mitigation procedures which conserve the historic values of the resources. American Indian religious values are also important elements to be considered when addressing decisions as to site preservation, protection, or alteration/removal. Among alternatives to consider are:

A. Adjustment of project boundaries to ensure complete avoidance of the site as well as protection of its environmental setting, where necessary.

B. Adoption of methods or techniques that will minimize disturbance to the site and its environmental setting.

C. Meeting "The Secretary of the Interior's Standards for Historic Preservation Projects" for projects involving historic structures.

D. Removal of the cultural property (historic) to another appropriate location after documentation of the property in place.

E. Mapping, photo-documentation and scaled drawings of historic properties before proceeding with project implementation.

F. Excavation of archaeological sites utilizing a professionally sound research design in keeping with the State-wide research plan, and carried out in consultation with interested American Indian groups. Such excavation would be undertaken through contract.

2. Protect eligible cultural resources from degradation due to public use and natural deterioration. Protection plans may include, but are not limited to, scientific study and collection, the use of fences and barriers, proper use or removal of signs, stabilization techniques, closure orders,

patrol and site monitoring, maintaining site anonymity, and gaining public understanding and support through education.

3. Buildings listed on the National Register of Historic Places or buildings eligible for listing, will be maintained to the maximum extent practical.

4. Provide opportunities for scholarly/scientific use of designated prehistoric and historic sites. This may require "banking" of sites for future use, coordination with American Indian groups, and processing of antiquities permits for testing and excavation of sites by qualified professionals.

5. Apply the SI-2 prescription to future cultural properties based on National Register eligibility, scientific values, and/or American Indian concerns.

6. Interpret suitable cultural resource properties for the recreational use and educational benefit of the general public. The measure of suitability should be based on accessibility to the public, feasibility for protection, condition of the property, compatibility with other resource management activities within or adjacent to the area, thematic representation, and value to public groups. Interpretive services and facilities should be compatible with the nature, quality, and integrity of the cultural sites selected for enhancement. Preferred methods include brochures, signs, and self-guided tours. Handicapped access to interpreted sites should be provided wherever practicable. Coordination with the American Indian community and involvement of interested volunteer groups and appropriate educational institutions will be encouraged.

Recreation Facility and Site Reconstruction

1. Prior to converting a qualifying campground to a fee site designation or expending capital investments to convert unqualifying campgrounds to fee site standards through reconstruction, an analysis will be made to assure such a conversion is justified. Some basic considerations to be used are: public demand, current and 10-year projected use, and other recreation facilities and opportunities present in the general area.

STANDARDS AND GUIDELINES

2. Recreation site reconstruction and improvement will be accomplished through partnerships and cooperative ventures to the maximum extent possible.

3. Recreation site reconstruction will be completed to high quality standards in harmony with development scale of the site, ROS Class, and public desires and expectations for the site.

Recreation Facility and Site Construction

1. New campground development will generally be constructed to full service standard and to the development scale level and the Recreation Opportunity Spectrum Class criteria that is appropriate for the site considering its location and setting.

2. Construction of new sites will be based on an analysis of user demand, use of currently available facilities, projected future demands, and expressed public interest.

Recreation Facility and Site Management

1. Manage recreation sites to provide a high degree of security, safety, and sanitary conditions for recreation visitors.

2. Provide high quality maintenance of facilities that assures a positive public image and a high degree of visitor satisfaction.

3. Keep abreast of visitor's needs and desires at recreation sites and adjust management programs to meet these needs.

Visitor Use Administration

1. Information programs such as recreation reports, news releases, radio and television reporting, video productions, and information tours will continue to be emphasized as means to keep the public informed of management activities.

2. Contacts with the public will anticipate management problems. Contacts will be based on

high quality public service and positive and effective communication. Contacts will seek to improve user land use ethics, encourage "light on the land" use techniques, and minimize conflicts.

3. Regulations to restrict or limit use will be employed only after all reasonable means have been exhausted to resolve conflicts between users and user groups.

4. Regulations and restrictions on Forest visitors will be well coordinated between Districts and adjacent Forests to avoid unnecessary contradiction or needless public confusion. However, logical deviation and flexibility will be maintained in user administration.

5. Incorporate interpretive and outdoor environmental education programs into activities available at appropriate developed sites.

Trail Reconstruction

1. Trail reconstruction will be accomplished in accordance with established objectives for each trail.

2. Meet visual management objectives and applicable ROS Class criteria in reconstruction design to assure appropriate recreation experience of the trail.

Trail Construction

1. Construct new trails to meet specific recreation management objectives, provide additional opportunities, solve user conflicts, and meet public demand where development of new trails is compatible with other land uses.

2. Newly constructed trails will meet visual management objectives and applicable ROS Class criteria for the areas accessed by the trails.

3. Design trails to provide a variety of recreation experiences as well as to access destinations or complete loop opportunities.

4. Plan the development and location of winter trails for snowmobile, cross-country skiing, snowshoeing, dog sledding, etc., to coordinate

with other resource values, management activities, and various management prescription criteria.

Trail System Maintenance and Operation

1. The Forest trail system will provide for use by all specified modes of transportation as contained in the management prescriptions.
2. Trail closures will be made only where needed to minimize disturbance to wildlife; prevent user conflicts; to protect soil, water, visual, vegetative, and cultural resources; control heavy use or to meet legislative requirements; and provide for public safety.
3. Trail maintenance will be performed to a standard or level that is compatible with established trail objectives for that trail and in conformity with ROS Class criteria.
4. All trails in the system will be protected from impact, or restored to at least the pre-existing condition, from all Forest management activities. Trails may be bisected by new road construction when no reasonable alternative exists, but mitigation will be completed to restore the usability of the trail.
5. Winter trails will be added to the system, and receive protective mitigation considerations equal to the summer Forest Trail System.
6. In trail system planning and inventory, establish objectives for each system trail identifying purpose, intent, or role of the trail, opportunities provided by the trail, use levels, and public expectations of the trail. Use trail objectives as a guide in construction or reconstruction planning and in establishment of maintenance levels.

WILDERNESS

Wilderness Recreation Opportunity Spectrum Classes

The Wilderness Recreation Opportunity Spectrum (WROS) provides a way to describe the variations in the degree of isolation from the sounds and influences of people, and the amount of recreation visitor use. There are four WROS classes; Pristine, Primitive, Semi-Primitive, and Transition.

1. Pristine

The area is characterized as an extensive, unmodified, natural environment. Natural processes and conditions have not been measurably affected by the actions of users. The area will be managed as free as possible from the influences of human activity. Terrain and vegetation allow extensive and challenging cross-country travel.

a. Physical-Biological Standards

(1) Vegetation

- (a) Area of vegetation loss, and compacted bare mineral soil at any campsite, should not exceed 225 square feet.
- (b) Trampled area of vegetation with season recovery should not exceed 400 square feet.
- (c) No loss of trees, or trees with exposed roots at any campsite.
- (d) No noticeable modifications of natural plant succession due to stock grazing or human activity.
- (e) No loss of dead trees or noticeable loss of dead, woody debris due to campfires.

(2) *Soils*

(a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates the natural process.

(b) Soil compaction should not occur in this class outside existing established campsites.

(3) *Water Quality*

There should be no measurable change in water quality due to human activity.

(4) *Air Quality*

Air quality will not be degraded as a result of campfire smoke, or Forest Service Management activities outside of wilderness in Class I areas.

(5) *Fish and Wildlife*

Visitor use shall seldom and only temporarily displace wildlife populations.

(6) *Scenery*

(a) No campsites should be visible from any other campsite.

(b) Human activity inside Wilderness should remain subordinate in foreground viewing and not be recognizable in middle-ground viewing areas.

(7) *Livestock Allotment*

This class should not include commercial livestock allotments so that the area is free as possible from human influences and to maintain the total integrity of natural ecological processes.

b. Social Standards

(1) *Encounters*

There should be an 80 percent probability that not more than one individual or party will be encountered per day during the primary use season.

(2) *Party Size*

The maximum party size shall not exceed a combination of 12 people and/or livestock, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness). A total of not more than six people will be encouraged in this class, and use of stock will not be encouraged for cross-country travel.

(3) *Campsites*

There shall be no other campsites visible or audible from any campsite. New user developed campsites will not be allowed to become established. When found, fire rings and tent frames will be disassembled and dispersed.

(4) *Pets*

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other resource impact.

c. Managerial Standards

(1) *Regulations and Information*

(a) Posting of information and regulations regarding this class will be located at trail-heads.

(b) Formal orders and permits may be required to achieve management objectives in this class.

(c) Ranger patrols and administrative contacts should be rare in this class and kept to the minimum necessary to meet management objectives.

(d) Signs will generally not be present, but may be used in rare circumstances to protect Wilderness resources.

(e) Recreation visitor travel routes will not be readily noticeable or may appear to be wildlife trails.

(2) Trails

There shall be no system trails in this class. User travel should be managed so that travel routes are not readily apparent or appear to be wildlife trails.

(3) Resource Protection Facilities

Facilities such as stock holding corrals are not appropriate in this class. Areas receiving visitor use numbers sufficient that facilities are necessary to protect resources should not be classified Pristine, or use should be controlled to maintain pristine conditions.

Temporary signs may be necessary to inform visitors of soil and vegetation rehabilitation projects.

2. Primitive

The area is characterized by an essentially unmodified, natural environment. Concentrations of visitors are low and evidence of human use is minimal. The area has high opportunity for isolation, solitude, exploration, risk, and challenge.

a. Physical-Biological Standards

(1) Vegetation

(a) Area of vegetation loss, and compacted bare mineral soil at any campsite should not exceed 400 square feet.

(b) There should be no loss of trees at any site and fewer than four trees with exposed roots per impacted site.

(c) No noticeable, long-term modification of natural plant succession as a result of livestock grazing or human activity.

(d) Dead trees or dead, woody debris may be utilized for campfires in amounts that can be replaced annually through natural accumulation.

(2) Soils

(a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates natural processes.

(b) Soil compaction should not exceed limits which will prevent natural plant establishment and growth except at well established campsites.

(3) Water Quality

There should be no change in water quality except for temporary changes that return to normal when activity ceases.

(4) Air Quality

Air quality will not be degraded as a result of campfire smoke, or Forest Service Management activities outside of wilderness in Class I areas.

(5) Fish and Wildlife

Visitor use may temporarily displace wildlife, but should not displace wildlife from critical habitat during critical periods. (Such as fawning and winter range.)

(6) Scenery

(a) Campsites will occasionally be visible from other campsites.

(b) Human activity should remain subordinate in foreground viewing and not recognizable in middle-ground viewing.

STANDARDS AND GUIDELINES

(7) *Livestock Allotments*

Commercial livestock is permitted in this class under approved management plans to the extent that this use is compatible with Wilderness resource values.

b. Social Standards

(1) *Encounters*

There should be an 80 percent probability that not more than either seven parties or seven individuals traveling alone will be encountered per day during the primary use season.

(2) *Party Size*

The maximum party size shall not exceed 12 people and/or livestock combined, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness).

(3) *Campsites*

There shall be no more than one campsites visible or audible from any campsite, or closer than 500 feet in open country.

(4) *Livestock*

Grazing stock is permitted except in established camp areas. Repeated stock use in cross-country travel by a single route shall be discouraged.

(5) *Pets*

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other resource impact.

c. Managerial Standards

(1) *Regulations and Information*

(a) Posting of information and regulations regarding this class will be located at trail-heads.

(b) Formal orders and permits may be required to achieve management objectives in this class.

(c) Ranger patrols and administrative contacts will occur periodically. Personnel involved in project work or monitoring will be present. Management personnel should conform to party size limitations and social standards for this class.

(d) Signs will be kept to the minimum to protect Wilderness resources. No signs will be provided to indicate destinations.

(e) Visitor travel routes may be noticeable, but should appear as wildlife trails.

(2) *Trails*

System trails are present in this class generally at low density. Some user developed trails may exist, but are not encouraged for use and rarely upgraded to system trails. If user-developed trails become well established, management action should be taken to rehabilitate damage and discontinue use. Reroutes of existing trails may be done to protect resources or to meet wilderness objectives. New trail construction in trailless drainages or to new destinations must be considered in the Forest Planning process.

(3) *Resource Protection Facilities*

Facilities that are essential for resource protection and visitor safety are appropriate in this class. Only native or natural appearing construction materials will be used. There will be no facilities provided for user comfort or convenience.

3. Semi-Primitive

The area is characterized by a predominantly unmodified environment of at least moderate size. System trails and campsites are present and there is evidence of other uses. A minimum of on-site controls and restrictions are implemented to protect physical, biological, and social resources. Some facilities may be present to reduce visitor impact.

a. Physical-Biological Standards

(1) *Vegetation*

(a) Area of vegetation loss, and compacted bare mineral soil at any campsite, should not exceed 625 square feet.

(b) There should be no loss of trees at any site and only six trees per site with roots exposed or which show signs of human use impact.

(c) There should be no long-term modification of plant succession and only short-term modification due to human activity or livestock grazing that can recover in one growing season.

(d) Dead trees or dead, woody debris may be utilized for campfire wood in amounts that can be replaced annually through natural accumulation.

(2) *Soils*

(a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates natural processes.

(b) Soil compaction should not exceed limits which will prevent natural plant establishment and growth, except at desired campsites, and in designated trail treads.

(3) *Water Quality*

There should be no change in water quality except for temporary changes that return to normal when activity ceases.

(4) *Air Quality*

Air quality will not be degraded as a result of campfire smoke or Forest Service Management activities outside of wilderness in Class I areas.

(5) *Fish and Wildlife*

(a) Visitor use should not displace wildlife from critical areas during critical periods.

(b) Riparian areas should appear to be unchanged by human or livestock use.

(c) Displacement of wildlife due to visitor use may be significant but should be of short duration to assure a natural ecosystem is maintained. Visitor use should not decrease habitat effectiveness for one species more than 20 percent.

(6) *Scenery*

(a) Campsites will be visible at times from other campsites.

(b) Human activity in wilderness, should remain generally subordinate in foreground viewing and not recognizable in middle-ground viewing.

(7) *Livestock Allotments*

Commercial livestock is permitted in this class under approved management plans to the extent that such use is compatible with all resource values.

b. Social Standards

(1) *Encounters*

There should be an 80 percent probability that not more than either ten parties or ten individuals traveling alone, will be encountered per day during the primary use season.

STANDARDS AND GUIDELINES

(2) *Party Size*

The maximum party size shall not exceed 12 people and/or livestock combined, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness).

(3) *Campsites*

There shall be no more than two campsites visible or audible from any campsite, or closer than 500 feet in open country.

(4) *Livestock*

Grazing of stock is permitted except in established camp areas.

(5) *Pets*

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other social or biological impact.

c. Managerial Standards

(1) *Regulations and Information*

(a) Posting of information and regulations regarding this class will generally be done at trailheads. Some regulatory signing may be posted at key locations such as lakeshores and campsites to help gain user compliance.

(b) Formal orders and permits may commonly be used to achieve management objectives in this class.

(c) Ranger patrols and administrative contacts will occur more frequently in this class, particularly at popular destination points and on weekends during the primary visitor use season. Personnel involved in project work or monitoring activities will be present. Major work projects should be planned as much as possible during low visitor-use periods. Management personnel should conform to party size limitations and be aware of their potential to impact visitor experiences.

(2) *Trails*

The managed trail system should be maintained or constructed toward more and most difficult trail standards (FSH 2309.18). However, trails classified easiest may exist in areas of gentle terrain and valley bottoms. A variety of user restrictions may be implemented to resolve negative resource impacts.

(3) *Resource Protection Facilities*

Facilities will be as natural appearing as possible or will be constructed out of native material. No facilities will be constructed for user convenience or comfort. Facilities will be placed so as to concentrate heavy impact on areas previously impacted and on sites capable of withstanding high impacts.

4. Transition

The area is characterized by a predominantly unmodified environment, however, the concentrations of visitors may be moderate to high at various times. The area is characterized as having a large number of day users who are often mixed with overnight and long-distance travelers on trails near trailheads and wilderness boundaries.

a. Physical - Biological Standards

(1) *Vegetation*

(a) Area of vegetation loss, and compacted bare mineral soil at any campsite, should not exceed 1000 square feet.

(b) There should be no loss of trees at any site and only ten trees per site with roots exposed or which show signs of human use impact.

(c) There should be no noticeable long-term modification of plant succession and only short-term modification due to human activity or livestock grazing, that can recover in one growing season.

(d) Dead trees, or dead woody debris, may be utilized for campfire wood in amounts that can be replaced annually through natural accumulation.

(2) *Soils*

(a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates natural processes.

(b) Soil compaction should not exceed limits which will prevent natural plant establishment and growth, except at desired campsites, and on designated trail treads.

(3) *Water Quality*

There should be no change in water quality except for temporary changes that return to normal when activity ceases.

(4) *Air Quality*

Air quality will not be degraded as a result of campfire smoke, or Forest Service Management activities outside of Wilderness in Class I areas.

(5) *Fish and Wildlife*

(a) Visitor use should not displace wildlife from critical habitat areas during critical periods. If conflicts occur, management actions should be implemented to reduce the impact.

(b) Riparian areas should appear to be unchanged by human or livestock use.

(c) Displacement of wildlife due to visitor use may be significant but should be of short duration to assure a natural ecosystem is maintained. Visitor use should not decrease habitat effectiveness for one species more than 20 percent.

(6) *Scenery*

(a) Campsites will be visible at times from other campsites.

(b) Human activity should remain generally subordinate in foreground viewing and not recognizable in middle-ground viewing.

(7) *Livestock Allotments*

Commercial livestock is permitted in this class under approved management plans to the extent that grazing use is managed to protect wilderness resource values.

b. Social Standards

(1) *Encounters*

There should be an 80 percent probability that not more than either 10-20 parties or 10-20 individuals traveling alone, will be encountered per day during the primary use season. Generally encounters should not exceed 10, however, in unique situations, encounters may reach 20 per day.

(2) *Party Size*

The maximum party size will not exceed 12 people and/or livestock combined, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness).

(3) *Campsites*

There shall be no more than three campsites visible or audible from any one campsite, or closer than 500 feet in open country.

(4) *Livestock*

Grazing of stock is permitted except in camp areas.

(5) *Pets*

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other biological or social impact. Visitors will be encouraged to leave pets at home in areas of higher visitor use.

c. Managerial Standards

(1) *Regulations and Information*

(a) Posting of information and regulations will generally be posted at trailheads but some regulatory signing may be necessary in key impact areas, or areas where there is potential for use conflicts.

(b) Formal orders and permits will commonly be used to achieve management objectives and visitor compliance in this class.

(2) *Administrative Presence*

(a) Ranger patrols and administrative contacts will occur most frequently in this class, particularly in high day-use areas and popular destination points. Personnel involved in project work and monitoring activities will be present.

(b) Work projects should be planned to be completed during low visitor use periods to minimize impact on visitors.

(c) Management personnel should conform to party size limitations and be aware of their potential to impact visitor experiences.

(3) *Trails*

The managed trail system should be maintained or constructed toward more and most difficult trail standards (FSH 2309.18). Trails classified easiest may exist in areas of gentle terrain and valley bottoms. A variety of user restrictions may be implemented to resolve negative resource impacts.

(4) *Resource Protection Facilities*

Facilities will be natural appearing or will be constructed out of native material. No facilities will be constructed for user convenience or comfort. Facilities will be placed so as to concentrate heavy impact on areas previously impacted and at sites capable of withstanding high impacts.

Limits Of Acceptable Change

Table IV-15 lists the key indicators that will be measured in monitoring the physical, biological, and social conditions and the standards for each Wilderness Recreation Opportunity Spectrum Class.

TABLE IV-15
LIMITS OF ACCEPTABLE CHANGE STANDARDS

Indicators	Pristine	Primitive	Semi-Primitive	Transition
Vegetation loss and bare, compacted mineral soil at campsites (square feet)	225	400	625	1,000
Number of Trees with roots exposed, or percent (whichever is less)	0 0%	4 25%	6 25%	10 50%
Encounters--80% Probability--Maximum number of encounters per day when traveling--primary use season.	1	7	10	10-20 (Generally 10, but up to 20 on a case by case basis)
Party size-- People and stock combined.	12 (Encourage 6 or less people, 0 stock). 12 people and 18 animals in the Lake Chelan Sawtooth Wilderness	12	12	12
Campsites visible when occupied	0	1	2	3
Dead woody debris available for firewood	Appears to be natural levels compared to adjacent similar areas			

**PROPOSED THREATENED,
ENDANGERED, OR SENSITIVE SPECIES**

(Plants and Animals)

1. Threatened, endangered, and sensitive species will be identified and managed in cooperation with the USDI Fish and Wildlife Service and Washington Department of Wildlife (animals), and Washington Department of Natural Resources and Washington Natural Heritage Program (plants) for all projects.

2. All proposed projects that may involve significant habitat disturbances or changes, or have the potential to alter habitat of threatened, endangered, or sensitive plant and animal species, shall be inventoried to determine if any of these species are present.

3. Biological evaluations that indicate an activity may have an impact on threatened, endangered, and sensitive species should be reviewed with the state agency that is responsible for the species and recommendations considered in finalizing mitigation requirements for a project proposal.

4. Maintain and update lists and maps of plants and animals periodically as new information is collected. Maps will be high quality topographic maps, at 1:24,000 scale or larger. Submit pertinent Forest information to the Regional Office for updating Regional Forester's Sensitive Species lists, and to the appropriate agency for inclusion in state-wide data bases.

5. All Project Environmental Analyses will evaluate the effects of the project on threatened, endangered, and sensitive species.

Proposed Threatened and Endangered

1. Habitat for existing Federally classified threatened and endangered species shall be managed to achieve objectives of recovery plans.

2. Where a threatened or endangered species or suitable habitat is present in a project area, follow the Biological Assessment Process and the Consultation Procedures.

Proposed Sensitive Species

1. When sensitive species are present in a project area, follow the objectives in the Species Management Guide.

2. Species Management Guides shall be developed for each sensitive species. These plans should be developed on a regular basis by highest priority so that all guides are completed by the tenth year after approval of the Final Forest Plan (approximately six plans per year). Species Management Guides will more specifically identify by species the area to be managed, and contain more information for each species.

Although not protected by the Threatened and Endangered Species Act, sensitive species will receive special management consideration under Forest Service policy. All necessary actions will be taken to assure that management activities do not jeopardize the continued existence of a sensitive species through adverse modification of their essential habitat until their status is determined.

Plants

General standards and guidelines for plants are discussed above under the "Threatened, Endangered, and Sensitive Species" section.

Research is done to obtain information about habitat requirements, population biology, genetic variability, reproduction biology, etc. Research projects will be done on a cost-share basis in cooperation with the U.S. Fish and Wildlife Service, the Washington Natural Heritage Program, interested agencies, and private groups. Priorities for research will be developed cooperatively. Generally, the species most threatened will be given highest priority.

All habitat improvement projects for T, E, or S species will be small-scale and experimental in nature until such time as species responses are better understood. When species response to a specific improvements project can be predicted, projects can be larger in scale and practical in nature. Species management guides will be updated every other year.

AnimalsBald Eagle

1. Bald eagles and their habitat shall be protected and managed in accordance with the Pacific States Bald Eagle Recovery Plan. The following are the potential nest sites. Lake Wenatchee 1, Bumping Lake 1, Cle Elum Lake 1, Kachess Lake 1, Lake Chelan 2, Rimrock Reservoir 1, and Wenatchee River 1. Occupied bald eagle habitat will be monitored to determine the effectiveness of planned action and recovery efforts. The location of potential nest sites will be identified before new projects are implemented.

2. Informal consultation shall be initiated with the USDI Fish and Wildlife Service to discuss the question of "effect" when a project involving site disturbance is within one mile of a bald eagle nest (FSM 2670, Bald Eagle Management and Consultation).

3. Within two years of approval of the Forest Plan, prepare a Species Management Guide for the potential bald eagle habitat on the Forest. Consult the Bald Eagle Recovery Plan (Brown 1985), the "Bald Eagle Management Guidelines for Oregon and Washington" (USDI Fish and Wildlife Service 1981), and FSM 2670 for specific management guidelines.

4. Interim requirements for management of bald eagle habitat shall include completion of Bald Eagle Management Area (BEMA) plans for each nesting, foraging and roosting area.

5. Active bald eagle nest sites shall be protected. Manage each area under the territory zone concept until a BEMA plan is completed and the management area is established (Brown, 1985)

A. Primary zone. The primary zone will be not less than 1/4 mile from the nest, with actual size and shape of zone adjusted to include all the area near the nest tree that is actually utilized. Zone size can vary, reflecting local topography, potential for blowdown, and location of important habitat components. There will be no timber harvesting in the primary zone unless designed to enhance stand characteristics for the benefit of nesting eagles. Human activities in

the primary zone will be controlled year-round to insure that the site remains suitable as nesting habitat.

B. Secondary zone. The secondary zone extends from the primary zone out to a minimum of 800 meters from the nest; it minimizes disturbance and protects the primary zone. Zones need not be circular, but will reflect local physiographic conditions and the tolerance of the nesting pair to disturbance factors (Brown 1985). The width of the zone could be considerably wider, depending on the degree to which vegetation or topography screens the nest from potential disturbance. The zone will contain important roosting sites, perching sites, and alternative nest sites. Timber may be harvested in the secondary zone, provided eagle habitat requirements take precedence. Human activity in the secondary zone will be controlled only during the period when the birds are present, normally between January 1 and August 31.

6. Feeding and Roosting Sites. Regularly used feeding and roost sites shall be protected. Human activities will be controlled if they adversely affect the eagles use of a feeding area. Only those Forest practices that maintain the suitability of the area for eagle roosting will be used. The area encompassed will have at least a 400 meters radius, possibly up to a one-fourth mile radius.

7. Maintenance of Potential Nesting Habitat. Forest lands within one mile of foraging habitat (such as anadromous fish streams and lakes over 50 acres in size) are potential bald eagle nesting habitat. Potential nest sites will be surveyed for active nest sites.

Peregrine Falcon

1. Peregrine falcons are not known to nest on the Forest. However, nesting and feeding habitat exists. Sufficient existing nesting and feeding habitat will be protected to meet the objectives of the Pacific Coast Recovery Plan for the American Peregrine Falcon (USDI Fish and Wildlife Service 1982). The following are the potential located nest sites that will be maintained: Oak Creek/Teepee Creek, Tieton River, Kloochman Rock, Goose Egg Mountain, Rimrock, and

STANDARDS AND GUIDELINES

Stroback Ridge. Additional sites may need to be maintained.

2. Any nest found will be protected. Associated habitat (such as feeding areas) will be maintained, and enhanced when opportunities occur.

3. Within three years after implementation of the Forest Plan, an inventory should be completed cataloging suitable peregrine falcon habitat. When the inventory is completed, the Forest should complete habitat management and nest site management plans for peregrine falcons.

4. Occupied peregrine falcon habitat will be monitored to determine the effectiveness of planned action and recovery efforts.

Grizzly Bear

1. Send reports of grizzly bear sightings to the coordinator for the Forest Service and Washington Department of Wildlife for investigation as soon as possible.

2. Projects within the evaluation area that may affect habitat will have consultation done with the USDI Fish and Wildlife Service.

3. If resident grizzly bears are discovered, cooperate with the USDI Fish and Wildlife Service and Washington Department of Wildlife to appropriately manage the animals.

4. Implement recovery objectives should a recovery plan be completed.

Gray Wolf, Canadian Lynx, and California Wolverine

1. Investigate, evaluate, and monitor sighting reports in coordination with the Washington Department of Wildlife and the USDI Fish and Wildlife Service.

2. If resident animals are discovered, inform and cooperate with the USDI Fish and Wildlife Service and Washington Department of Wildlife to insure the protection of the animals.

3. Implement recovery objectives when a plan is completed.

Northern Spotted Owl

1. Spotted owl habitat shall be managed in accordance with direction specified in the Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide.

2. Areas proposed for harvest which contain habitat suitable for spotted owls will be surveyed according to standard inventory procedure. Maintain survey results in the Ranger District resource inventory and forward to the Forest Coordinator annually.

3. For Spotted Owls occupying non-network sites, protect nest tree and an area around it. Seek technical assistance of U.S. Fish and Wildlife Service and Washington Department of Wildlife in developing management strategies for these sites.

WILDLIFE AND FISHERIES

Wildlife and Fish Surveys and Plans

1. Wildlife and fish resources on the Wenatchee, in particular the habitat of indicator species, shall be managed in cooperation with fish and wildlife agencies. Project assessments and habitat improvement projects should be reviewed with appropriate agencies.

2. Coordinate, cooperate, and share costs when possible with the Washington State Department of Wildlife (for animals) and Washington Natural Heritage Program (for plants) in collection of habitat information, population statistics and inventories, and research on animal and plant species.

3. Fish and wildlife habitat shall be managed to maintain viable populations of all existing native and desired non-native vertebrate species in approximately their present distribution.

A. Maintain or enhance limited habitats to provide the habitat characteristics for dependent species. These habitats include, but are not limited to, cliffs, caves, talus, ponds, marshes,

wetlands, and areas of colony nesting species. Activities that need to be sensitive to limited habitat needs are logging, roads, trails, campgrounds, facilities, etc.

B. To maintain viable populations of raptors, protect all active nest and roost sites.

C. To provide viable populations of deciduous dependent species, maintain or enhance the deciduous and mixed conifer/deciduous tree habitat. Maintain activity levels that allow high use of deciduous habitat by wildlife.

4. Coordinate and cooperate with the Washington Department of Wildlife in relocation of animals. Add additional animals where habitat is under utilized and remove animals where habitat is over utilized.

5. All projects will be surveyed to locate habitats which are limited; e.g., for raptor nest and roost sites, deciduous tree habitat, meadows, and watering sites.

6. Strive to provide a high level of wildlife habitat diversity in each sub-basin (1,000 to 10,000 acre area).

7. Develop opportunities for public viewing of wildlife where low impact to animals can be assured, and when compatible with prescription objectives.

8. Expand the education/interpretive materials available so the public has the opportunity to be more appreciative of wildlife, fish, and plants and to enjoy the non-consumptive use opportunities provided.

9. Maintain and update habitat information and maps of sightings for species that have assessments done.

10. Coordinate to the extent possible with State and Federal fish agencies, Indian Tribes and the Northwest Power Planning Council's Fish and Wildlife Program to develop fish and fish habitat management objectives, by subdrainage.

11. Monitor to the extent practical, management indicator species to determine population trends

in relation to habitat conditions. Coordinate and cooperate in the monitoring with the Washington Departments of Fish and Wildlife and Treaty Indian Tribes.

12. Maintain and improve current and long-term fish habitat capability and distribution to accomplish natural production goals as established by State and Federal Fish Management agencies, Indian Tribes and the Northwest Power Planning Council's Sub-basin Planning Process.

13. Implement habitat and watershed surveys to quantify current habitat quantity, quality and production. Utilize approved methods to assess habitat quality and quantity and watershed conditions. The Forest will define baseline inventory parameters based upon Regional direction and monitoring of standards and prescription. Districts may add survey parameters as needed to meet specific objectives. Coordinate, cooperate and share costs where possible with State and Federal Fish Management agencies, Indian Tribes, and private groups in collection of habitat information and population statistics.

14. Update Geographic Information System, Total Resource Inventory or appropriate data base annually.

15. Provide support to other resource projects to evaluate the potential direct, indirect and cumulative effects of proposed activities on fish resources and fish habitat. Utilize professional judgement and technical evaluation on a subdrainage and site specific basis to predict and evaluate effects and prescribe appropriate mitigation.

16. Develop and annually update fish habitat management five year program by Ranger District to provide more specific direction in response to the framework outlined in Forest Plan. Utilize the five-year program as a planning and budgeting tool designed to identify personnel needs, support services, inventory strategy and improvement projects. The five-year program will provide a documented link between Forest Plan objectives and the program development and budgeting process which allows for detailed tracking of fish habitat goals, objectives and accomplishment for current and out-year(s). Coordinate the develop-

ment and revision of the program with the watershed section, other resource elements, State and Federal Fish Agencies, Indian tribes and private groups.

17. Develop fish habitat management objectives for drainages to help prioritize work activities including surveys and improvement projects. Update/revise as needed. Coordinate with other resources, State and Federal Fish Management Agencies, Indian tribes, public groups and Northwest Power Planning Council Sub-basin Planning process.

18. Develop opportunities for public viewing and education so that the public has the opportunity to be more appreciative of fish resources and non-consumptive uses.

Primary Cavity Excavator

Primary cavity excavators, as an indicator species, represent habitat for live defective trees, all decay stages of standing dead trees, and all decay stages of dead and down trees.

1. Provide all decay classes of dead and down trees. Provide an average of not less than two dead and down tree segments per acre in decay classes 1 and 2, well distributed over the area. Tree segments should be greater than 12 inches in diameter and a minimum of 20 feet long.
2. Live and hard dead trees with cavities will be preferred over those without cavities.
3. Establish assessment areas (sub-basins of 1,000 to 10,000 acres) and distribute primary cavity excavator habitat over a majority of the acres within the subbasin. At a minimum, habitat will be provided to maintain cavity excavators at 20 percent of their potential population size. Snag densities necessary to meet this level must be provided within land areas that are generally no larger than 40 acres in size.
4. Each prescription will achieve its assigned population goal for each sub-basin.
5. Maintain the same level of soft dead trees and large down trees as would be naturally created by the population goal for dead trees.

Big Game Management

1. Develop a species management guide for implementation of direction for each deer and elk winter range and mountain goat range. Guides should be completed as soon as possible to achieve meeting the direction in prescriptions. An estimated 15 mountain goat guides, 9 deer/elk guides, 7 deer guides, and 1 deer/bighorn sheep guide will be needed. Species management guides will establish more specific management information for each species.
2. Coordinate, cooperate, and share costs when possible with State and Federal fish and wildlife agencies, Indian Tribes, and private groups in the collection of habitat information, population statistics and inventories, research, and habitat improvement projects.
3. Cooperate and coordinate with the Washington Department of Wildlife to inventory, map and define elk and deer spring and fall range.
4. Coordinate with the Washington Department of Wildlife to map key habitat, winter and summer range for mountain goats and bighorn sheep.
5. Bighorn sheep and mountain goat requirements will take precedence over deer and elk requirements when conflicts in management occurs.
6. Prevent introduction of disease(s) from livestock into resident herds of bighorn sheep by identifying potential problem areas, and developing a plan to mitigate the identified problems.
7. Cooperate and coordinate with the Washington Department of Wildlife in closing some roads during hunting season to provide a variety of motorized and non-motorized hunting opportunities.
8. Generally, strive to provide well distributed cover over at least 40 percent of a subbasin in deer and elk summer range. It would be desirable to have 50 to 100 percent of this cover as thermal cover.

9. Strive to maintain forage areas for deer and elk of less than 40 acres in size. These should be surrounded by thermal and hiding cover. Thermal cover should be at least 20 percent of periphery of each unit.

10. Provide thermal cover for mountain goats to travel between summer and winter range.

11. Limit the roads in mountain goat summer range. Close as many of the roads in summer range as is reasonable while providing recreation access to trails, trail heads, and other areas of recreation activity and interest. Roads will not be built in mountain goat winter range when other reasonable alternatives exist.

12. Provide for an even flow of mountain goat habitat.

13. Discourage activities in key mountain goat winter and kidding range from Dec. 1 until July 1.

14. Manage migration routes of big game to provide enough hiding cover to facilitate travel.

Nonstructural Habitat Improvement

1. Implement cost effective habitat improvement projects that are needed to meet the Forest-wide and prescription directions.

2. Provide an economic analysis of each project.

3. Design the habitat improvements to help meet objectives of other resources, when practical.

4. Look for opportunities to share costs of habitat improvements with the Washington Department of Wildlife, other agencies, and private groups.

5. Improve forage quality and quantity in summer range in allocations other than prescriptions for big game (EW-1 and EW-3), when it is a limiting factor, and consistent with other resource objectives.

6. Strive to provide an abundance of herbaceous vegetation with a high nutrient content in the spring and fall range of big game.

7. For mountain goats create or maintain small openings of 0.5 to 5 acres of high quality forage in both summer and winter range.

8. Update the 10 year schedule for wildlife and plant improvement projects annually.

Structural Habitat Improvement

1. Implement cost effective habitat improvement projects where needed to meet the prescription direction.

2. Provide an economic analysis of each project.

3. Design habitat improvements to help meet the objectives of other resources, when practical.

4. Look for opportunities to share costs of habitat improvements with the Washington Department of Wildlife, other agencies, and private groups.

5. Develop watering facilities, for use by a variety of wildlife, where increases in wildlife are expected.

6. Increase primary cavity excavator habitat in allocations that are below the potential population objective as soon as possible.

7. Update the plan for wildlife and plant improvement projects annually.

Fish Habitat Improvements

1. Utilize sub-basin habitat objectives and five-year plans to prioritize and schedule habitat improvement projects.

2. Develop project plans based upon inventories, sub-basin objectives and Five-year Plans.

3. Schedule projects on a priority basis, upon sub-basin objectives Five-year plans and Forest-wide Activity Schedule (Appendix A). Rehabilitation of degraded habitat will have priority over enhancement projects.

STANDARDS AND GUIDELINES

4. Implement structural and non-structural fish habitat and watershed improvement projects as funded. Coordinate, cooperate and share costs when possible with other resources, State and Federal Fish Agencies, Indian tribes, private groups and the Northwest Power Planning Council Fish and Wildlife Program.

5. Provide maintenance of projects to assure fish habitat improvement projects are functional to meet objectives and protect investment. Annually monitor projects to prioritize maintenance needs. Develop an accounting system to record planned, completed projects and maintenance needs.

6. Annually complete Forest accomplishment report for distribution to Ranger Districts, Regional Office and outside groups.

7. Monitor habitat improvement projects as provided in Chapter V of the Forest Plan to determine effectiveness of projects at meeting stated objectives.

8. Increase fish habitat capability and watershed condition through implementation of rehabilitation and enhancement projects utilizing a variety of funding sources, including but not limited to, FRP, P&M, KV, and BPA funds. Coordinate with State and Federal Fish agencies, Treaty Indian Tribes, private groups, and the Northwest Power Planning Council's Fish and Wildlife Program.

RIPARIAN AREAS

Planning

Specify riparian management objectives for all projects to be implemented within the land and vegetation associated with Class I, II, III and IV streams, lakes, wetlands, seeps and springs.

1. Within Riparian Management Areas, management decisions will be made in favor of riparian dependent resources (e.g., water quality, fish and wildlife habitat) where conflicts exist.

2. Riparian area management will meet or exceed State and Federal Water Quality standards and

Washington State Forest Practices Rules and Regulations.

3. Riparian management objectives for projects will be established based upon an analysis of the existing and desired future conditions within both the project area and the subdrainage (generally 1,000-10,000 acres).

The Riparian Management Area (RMA) within which these objectives apply shall correspond to at least the recognizable area dominated by riparian vegetation (true riparian zone) and sufficient adjacent area (influence area) to assure adequate protection to achieve riparian management objectives and standards in the subdrainage. Utilize the following direction in identifying the width of the RMA:

1. RMA will include the true riparian zone, that zone of transition between the aquatic ecosystem and the terrestrial ecosystem that can be identified by soil characteristics and distinctive vegetative communities that require free or unbound water (FSM 2526.05).

2. The width of the "influence area" required adjacent to the true riparian zone will be determined on a site-specific basis considering factors such as surface erosion/delivery potential, mass erosion potential, large woody debris recruitment, shading needs, fine particulate organic matter input, etc.

A. The following table establishes RMA width based on the potential for sediment delivery from surface erosion into stream channels.

Table IV-16

Potential Erosion Hazard <u>1/</u>	Percent Slope Adjacent to Stream	Slope Distance from High Water Mark <u>2/</u>
High	0 %	100 feet <u>3/</u>
Mod/Low	0 %	100 feet
High	10 %	120 feet
Mod/Low	10 %	110 feet
High	30 %	160 feet
Mod/Low	30 %	130 feet
High	50 %	200 feet
Mod/Low	50 %	150 feet
High	70 %	240 feet
Mod/Low	70 %	170 feet

1/ Potential soil erosion hazard/risk based on Wenatchee National Forest Soil Resource Inventory.

2/ High: Distance increases at a rate of two feet for each one percent increase average slope
Mod/Low: Distance increases at a rate of one foot for each one percent increase in average slope.

3/ Example: A stream 20 feet wide at high water with average slope of 30% on one bank and 70% on the other bank on Mod/Low erosion potential would have an RMA width of 130 feet (30%) plus 170 feet (70%) plus 20 feet (high flow stream width) for a total of 320 feet.

B. Utilize existing or develop new guidelines to facilitate the determination of RMA width based on stream temperature (shade) and natural large wood recruitment.

C. The width of consideration for the Riparian-Aquatic Protection Zone (EW-2 Prescription) is defined by the table above.

Complete a floodplains and wetlands analysis for any project that has the potential to impact these sensitive areas. This analysis and all management activities within these areas will comply with the objectives of Executive Orders #11988 (Floodplains) and #11990 (Wetlands).

Administration

Utilize management prescriptions (such as EW-2) and apply site-specific management practices to achieve riparian management objectives.

The following standards and guidelines describe the desired end results for the various riparian classifications on the forest.

CLASS I, II AND III STREAMS, LAKES AND WETLANDS

The desired future condition for riparian areas on the Forest has been described in terms of four major components of riparian habitat: (1) Sediment, (2) Temperature, (3) Channel Morphology, and (4) Floodplain/ Riparian Vegetation. These four components of riparian habitat are most indicative of the health of the system. Standards that are measurable are identified for each component in order to define the parameters for evaluating riparian habitat conditions.

The focus of these standards is to provide riparian habitat conditions on a subdrainage basis to meet soil productivity standards, water quality standards, and fish and wildlife habitat objectives.

STANDARDS AND GUIDELINES

These standards are intended to be applied as a family of parameters to evaluate conditions and establish management objectives for riparian areas in each subdrainage. The standards provide a means to measure actual "on-the-ground" attainment of the desired future condition for riparian areas on the Forest.

The standards are end-result oriented. That is, they define what riparian habitat conditions need to be in order to meet goals and objectives. How the standards are to be met or maintained will be determined on a project basis depending on both the site conditions and the current and desired future condition of the subdrainage.

It is known that present conditions in some subdrainages on the Forest do not meet one or more of the measureable standards. When this is the case, an analysis needs to be made as to why the subdrainage does not meet a particular standard. A number of different situations might result from this analysis. If a subdrainage does not meet a standard due to man's activity, then a strategy and timeframe needs to be developed to achieve the standard. If man's activities have altered a subdrainage so that it is unlikely that a standard can ever be achieved, then a new standard needs to be developed for that area. If a standard cannot be achieved due to natural conditions, a new standard would need to be developed for that subdrainage.

Class I, II and Fish Bearing Class III Streams 1/

1. Sediment

a) Fines - Maintain <20% fines ($\leq 1.0\text{mm}$) as the area weighted average in spawning habitat (pool tail-outs and glides).

b) Macroinvertebrates - Maintain stream substrate so that ≥ 3 sediment sensitive macroinvertebrate species, typical of streams in the area, maintain densities of ≥ 200 individuals/m².

c) Turbidity - Meet State water quality standards for turbidity.

2. Temperature

a) The maximum temperature will be $\leq 61^\circ\text{F}$ on any day and/or the average 7-day maximum temperature will be $\leq 58^\circ\text{F}$

b) Where streams naturally exceed the above standards, management activities will not cause further measureable temperature increase.

3. Channel Morphology

a) Pools - (1) Alluvial, gravel or low gradient (<2%) streams will maintain one or more primary pools 2/ every 3 channel widths 3/.

(2) Boulder - Rubble or moderately steep gradient (>3%) streams will maintain one or more primary pools every 6 channel widths.

b) In-Channel Large Wood - Provide an average of ≥ 20 pieces (i.e., Key Pieces) 4/ of large wood/1,000 lineal feet ($\geq 100/\text{mile}$) on Class I, II and fish bearing Class III streams.

The minimum size standards to meet in-channel large wood requirements are as follows:

Minimum length 50 feet

Minimum diameter ≥ 12 inches (80%)

≥ 20 inches (20%) 5/

1/ Includes both perennial and intermittent streams as defined in FSM 2526 05 (See Glossary).

2/ Primary pools occupy $\geq 50\%$ of the low flow channel width and have a maximum depth of ≥ 36 inches

3/ Channel widths are bank-full widths

4/ Key wood pieces "in the channel" include those downed pieces meeting size requirements and having at least 20% of their length within the vertical plane established as perpendicular to the bankfull channel margin.

5/ Diameter refers to the mean diameter obtained as an average of the diameters of each end of the log

These dimensions are based on average minimum conditions, Forestwide. Different standards may be developed for some subdrainages when warranted by site-specific conditions (e.g., site potential).

4. Floodplain/Riparian Vegetation

a) Vegetative Ground Cover - Maintain $\geq 90\%$ vegetative ground cover provided by trees, shrubs, grasses, sedges and duff within the floodplain and true riparian zone.

Refer to the Forestwide Standards and Guidelines for Range Planning and Inventory for additional direction on vegetation management in riparian areas.

b) Potential Large Wood - Maintain ≥ 20 live conifer trees per acre ≥ 20 " d.b.h. in order to meet in-channel wood standard.

As with the in-channel wood standard, this standard describes minimum average conditions, Forestwide. Different standards may be developed for some subdrainages when warranted by site-specific conditions (e.g., site potential). The intent of this potential large wood standard is to meet the in-channel large wood standard over time.

The actual number of trees maintained on most sites will be the net result of project prescriptions designed to meet all the riparian standards, including stream temperature, sediment and dead/defective tree habitat. Refer to the "Administration" section for further information on application of these guidelines.

c) Vegetative Composition - At a minimum, meet Washington State Forest Practice Rules and Regulations for leave tree requirements in riparian areas. Maintain riparian habitat diversity associated with deciduous trees as would be expected on the site.

d) Dead/Defective Tree Habitat - Manage RMA dead/defective tree habitat at 80% of the theoretical biological potential within the subdrainage.

e) To provide viable populations of wildlife, manage the edges of lakes to provide wildlife undisturbed access to at least 20% of the RMA.

5. Fish Passage

a) All new road construction shall maintain or enhance fish passage.

b) Identify man-made fish passage barriers. Develop and implement plans for correction of passage problems on a priority basis.

Lakes and Wetlands

1. Floodplain/Riparian Vegetation - Standards for lakes and wetlands for this riparian habitat component are the same as those listed above for Class I, II and Fish Bearing Class III Streams.

Non-Fish Bearing, Class III Streams 1/

1. RMAs associated with non-fish bearing, perennial streams are managed to meet standards and subdrainage objectives for fish habitat, water quality and riparian associated wildlife habitat. Because of the wide diversity of these types of channels across the Forest, a variety of prescriptions will need to be applied based upon the site and subdrainage objectives for riparian dependent resources.

a) Sediment - Limit sediment loading and maintain channel conditions necessary to meet standards in fish-bearing streams. Refer to the variable width table above for initial guidance on determining RMA width considering erosion potential.

b) Temperature - Management along these streams will not increase temperatures in fish bearing streams above standards.

1/ Includes non-fish bearing, perennial streams not meeting higher class criteria as defined in FSM 2526.05 (See Glossary).

c)Channel Morphology

(1)Pools - Same as Class I, II and fish bearing Class III streams except no Forestwide depth requirement. Recognize the role of pools in providing habitat diversity and in regulating the flow of materials through these stream systems. (e.g., diversity for aquatic organisms and terrestrial wildlife; streamflow energy dissipation, etc.)

(2)In-Channel Large Wood - Same as Class I, II and fish bearing Class III streams except minimum piece length is two bankfull channel widths and numbers apply as an average condition for non-fish bearing, perennial streams in a subdrainage.

d)Floodplain/Riparian Vegetation

(1)Vegetative Ground Cover - Maintain $\geq 90\%$ ground cover provided by trees, shrubs, grasses, sedges and duff within the floodplain/true riparian zone.

Refer to the Forestwide Standards and Guidelines for Range Planning and Inventory for additional direction on vegetation management in riparian areas.

(2) Potential Large Wood - Maintain trees necessary for sideslope stability, channel stability, long-term large wood input and wildlife habitat diversity.

(3) Dead/Defective Tree Habitat - Manage so that as an average subdrainage condition, RMA's associated with these streams provide dead/defective tree habitat at 80% of the theoretical biological potential.

CLASS IV STREAMS, SEEPS AND SPRINGS
1/

1. Manage Class IV streams so as to not adversely impact water quality, fish habitat and viable wildlife populations and water quality in the subdrainage. Give special consideration to land and vegetation adjacent to Class IV stream

1/ Includes non-fish bearing, intermittent streams not meeting higher class criteria as defined in FSM 2526.05 (See Glossary).

channels to meet riparian management objectives for the subdrainage. Emphasis is on maintenance of bank and channel stability. Maintain wood necessary for channel maintenance and control. Recognize the importance of Class IV streams, seeps and springs in providing wildlife habitat diversity and maintain diversity necessary to accomplish subdrainage objectives.

a) Protection of channel stability and wildlife habitat diversity associated with Class IV streams, seeps and springs is usually accomplished by cutting area design, logging method selection, maintenance of duff or low ground vegetation and brush. As needed, leave conifer or hardwood trees necessary for bank stability, long-term wood input and wildlife habitat diversity. Forest standards for dead/defective tree habitat are expected to provide wood needed for bank stability, wildlife habitat diversity and long term wood input to the channels.

b) In Class IV stream channels leave all naturally downed large woody material within or across the vertical plane established as perpendicular to the bankfull channel margin, unless on-site evaluation indicates that this material poses an unacceptable risk of damage.

c) Maintain sufficient habitat along Class IV stream channels, seeps and springs to provide viable populations of amphibians. Habitat needs to be well distributed throughout subdrainages on the Forest.

RANGE

Range Planning and Inventory

1. Allotment management plans will be written or revised to meet the goals and objectives for the management area in which the allotment is located.

2. Areas of suitable range outside of existing allotments will be incorporated into existing or new allotments for use by livestock to help:

- A. Solve overuse on problem allotments;
- B. Meet other resource objectives;
- C. Meet demand for forage.

3. As part of the analysis of new allotments or re-analysis of existing allotments.

A Identify lands in unsatisfactory condition, see glossary. Develop allotment management plans with specific objectives for these lands on a priority basis under a schedule established by the Forest Supervisor. These objectives will define a desired future condition based on existing and potential values for all resources. The allotment plan will include: 1) a time schedule for improvement, 2) activities needed to meet forage objectives; and 3) an economic efficiency analysis

B. Identify allotments with riparian areas in unsatisfactory condition, i.e. 1) on suitable range, forage condition is not at least fair, with a stable trend, or 2) classification is PC-basic resource damage or PD-other resource damage, see glossary.

C. Range allotment management plans will include a strategy for managing riparian areas. A measurable desired future riparian condition will be established based on existing and potential vegetative conditions.

When the current riparian condition is less than that desired, objectives will include a schedule for improvement. The allotment management plans will identify management actions needed to meet riparian objectives within the specific time frame. Measurable objectives will be set for key parameters, such as stream surface shaded, streambank stability, and shrub cover. This process is described in "Managing Riparian Ecosystems (Zones) for Fish and Wildlife in Eastern Oregon and Eastern Washington" (1979). The plan will address the monitoring needed to determine if the desired rate of improvement is occurring. Allotment management plans currently not consistent with this direction will be developed or revised on a priority basis under a schedule established by the Forest Supervisor

Range Non-Structural Improvements

1. Refer to Non-Structural Range Improvement Handbook.

Range Structural Improvement Maintenance

1. Maintain all structural improvements at, or as near as practical to, the standard to which they were constructed.

Range Administration and Management

1. When allotment boundaries do not follow management area boundaries, grazing management systems will be designed to meet the highest prescribed levels of management contained in the appropriate management prescriptions

2. Utilize livestock as a tool to manipulate vegetation in achieving other resource objectives

3 Forage utilization by livestock will generally follow established allowable use guides (Tables IV-17 and IV-18), however, percent use will be adjusted up or down to meet total resource needs

Noxious Farm Weeds

1. Cooperate with the Washington State Noxious Weed Control Board and other state, county and local agencies and organization in the identification, location, prevention and spread of noxious farm weeds.

2. Develop an Action Plan for inventory and monitor populations of noxious weed populations on the Wenatchee National Forest

3. Conduct a noxious weed assessment for all significant ground disturbing project activities to determine the risk of introducing noxious weeds and develop a plan to prevent introduction on moderate and high risk sites.

4. Contain, control or eradicate existing populations as budget allows. Give priority as follows:

TABLE IV-17
RIPARIAN AREAS - FORAGE UTILIZATION
ALLOWABLE USE OF AVAILABLE FORAGE 1/

RANGE RESOURCE MANAGEMENT LEVELS (FSH 2209.21 R-6)	MAXIMUM ANNUAL UTILIZATION (percent)			
	Grass & Grasslike ^{2/}		Shrubs ^{3/}	
	Sat.Cond.4/	Unsat.Cond.5/	Sat.Cond.4/	Unsat.Cond.5/ ⁶
B - Livestock use managed within current grazing capacity by riding, herding and salting. Cost-effective improvements used only to maintain stewardship of range.	40	0-30	30	0-25
C - Livestock managed to achieve full utilization of allocated forage. Management systems designed to obtain distribution and maintain plant vigor include fencing and water development.	45	0-35	40	0-30
D - Livestock managed to optimize forage production and utilization. Cost effective culture practices improving forage supply, forage use & livestock distribution may be combined with fencing and water development to implement complex grazing systems.	50	0-40	50	0-35

1/ This will be incorporated in Allotment Management Plans. Allotment Management Plans may include utilization standards which are either lower or rarely higher when associated with intensive grazing systems and specific vegetation management objectives which will meet objectives for the riparian dependent resources. Includes cumulative annual use by big game and livestock.

2/ Utilization based on percent removed by weight

3/ Utilization based on incidence of use, weight, and/or twig length.
 Example: If 50 leaders out of 100 are browsed, utilization is 50 percent

4/ Satisfactory Condition - see glossary (satisfactory condition is determined by allotment classification and/or forage condition)

5/ Unsatisfactory Condition - see glossary (anything not "satisfactory").

TABLE IV-18
SUITABLE RANGE (EXCEPT RIPARIAN)
ALLOWABLE USE OF AVAILABLE FORAGE ^{1/}

RANGE RESOURCE MANAGEMENT LEVELS (FSH 2209.21 R-6)	MAXIMUM ANNUAL UTILIZATION (percent) ^{2/}					
	Forest		Grassland		Grass and Grasslike	
	Sat. Cond.3/	Unsat. Cond.4/	Sat. Cond 3/	Unsat Cond.4/	Sat. Cond.3/	Unsat. Cond 4/
B - Livestock use managed within current grazing capacity by riding, herding and salting. Cost-effective improvements used only to maintain stewardship of range.	40	0-30	50	0-30	40	0-25
C - Livestock managed to achieve full utilization of allocated forage. Management systems designed to obtain distribution and maintain plant vigor include fencing and water development.	45	0-35	55	0-35	45	0-30
D - Livestock managed to optimize forage production and utilization. Cost effective culture practices improving forage supply, forage use & livestock distribution may be combined with fencing and water development to implement complex grazing systems.	50	0-40	60	0-40	50	0-35

^{1/} This will be incorporated in Allotment Management Plans. Allotment Management Plans may include utilization standards which are either lower or rarely higher when associated with intensive grazing systems and specific vegetation management objectives which will meet resource objectives. Includes cumulative annual use by big game and livestock.

^{2/} Utilization based on percent removed by weight for grass, grasslike, and forbs.

^{3/} Satisfactory Condition - see glossary (satisfactory condition is determined by allotment classification and/or forage condition).

^{4/} Unsatisfactory Condition - see glossary (anything not "satisfactory").

Priority by Noxious Weed Class

1. Class "A" - those noxious weeds not native to the State that are of limited distribution or are unrecorded in the State and pose a serious threat to the State.
2. Class "B Designate" - those noxious weeds (designated by the state) not native to the State that are of limited distribution or are unrecorded in a region of the State and are common in other regions of the State.
3. Class "C" - any other noxious weeds as identified by the Forest Supervisor.
4. Class "B Non-designated" noxious weeds.

Priority by Location

1. Projects that are next to agricultural lands or areas threatening Federally listed threatened, endangered and sensitive plant or animal species.
2. Projects that are along the Forest boundary or within or threatening Congressionally designated Wilderness area(s).
3. Areas in or adjacent to commodity producing areas.
4. Areas adjacent to disturbed areas.
5. Projects within or adjacent to visually sensitive areas.
6. All other locations.

TIMBER

Regeneration Harvest

1. Immature understories of existing stands which are candidates for an overstory removal may be retained for further management if the residual stand contains a minimum of 50 well distributed trees per acre. These trees should be a desirable species, well formed, free to grow after overstory removal, and capable of a radial growth rate of 15 annual rings per inch or better within five years after release. Multi-level stands which do not meet the above understory minimums should be scheduled for regeneration harvest at the appropriate time rather than overstory removal.

Intermediate Harvest

1. Intermediate harvests should be designed to improve quality, vigor, and value of the residual stand and not necessarily to maximize return from the intermediate harvest.

Silvicultural Examination and Prescription

1. The selected silvicultural system must be capable of providing special conditions, such as a continuous canopy or continuous high density live root mats when required by critical soil conditions, or conditions needed to achieve management objectives such as streamside protection, wildlife needs, and visual resources.
2. The selected silvicultural system must permit control of existing or potential vegetation to a degree that establishment of numbers of trees, other desirable vegetation, and rates of growth as identified in site specific silvicultural prescriptions for harvest areas, can be achieved.
3. The silvicultural system selected must promote stand structure and species composition which avoids serious risk of damage from mammals, insects, disease, or wildfire and will allow treatment of existing insect, disease, or fuel conditions.
4. Silvicultural prescriptions will be prepared on a site specific basis for all activities proposing the management of trees or timber stands to meet resource objectives. All prescriptions will be prepared or approved by a certified silviculturist.
5. The silvicultural prescription shall consider integrated pest management. Pests include insects, diseases, animals, and vegetation. Pesticide application shall conform to Regional direction.

Reforestation

1. The selection of any particular treatment method will be made at the project level based on a site-specific analysis of the relative effectiveness, environmental effects (including human health), and costs of the feasible alternatives. Herbicides will be selected consistent with the

basis established in the Final Environmental Impact Statement For Managing Competing and Unwanted Vegetation. Monitoring and enforcement plans to implement specific measures will be developed for site-specific projects and evaluated in the environmental analyses for these projects.

2. Natural regeneration opportunities will be utilized as appropriate to supplement planting of tree improvement stock.

3. In regeneration units, site preparation should be completed concurrently with logging, or one year after harvest. Units should be suitable for certification within five years after the regeneration harvest. Exceptions may occur, but only for resource objectives that have been documented through environmental analysis.

4. Regional and local stocking guides should be utilized to assess adequate stocking on all regeneration units prior to certifying them as being satisfactorily reforested. Minimum stocking is 150 well distributed trees per acre of a species suitable to the site.

Timber Stand Improvement

1. The actual number of trees for satisfactory reforestation may range from 150 to 500 trees per acre. Variations depend on species and tree sizes found on the site. Stands with more than 500 trees per acre normally need thinning to optimize growth.

2. Release projects shall be governed by the Final Environmental Impact Statement for Managing Competing and Unwanted Vegetation. Prevention of problems shall be the overriding principal.

3. Fertilization can be done where positive net public benefits are expected, based on past research and local experience.

Timber Sale Preparation and Timber Harvest Administration

1. Forest openings created by the application of even-aged silviculture shall be limited to a maximum size of 40 acres. Exceptions are permitted in the following cases: When natural catastrophic

situations such as fires, windstorms, or insect and disease outbreaks occur; on an individual case basis after 60 day public notice and review by the Regional Forester; or, when any one of the criteria described below is met and will produce a more desirable combination of benefits, the limits may be exceeded by not more than 50 percent without review by the Regional Forester and 60 day public notice.

Criteria for 50 Percent Exception

A. When larger created openings will reduce the disturbance to soil, water, fish, riparian resources, or residual vegetation by: allowing economically feasible logging systems that reduce landing and road construction; or locating roads away from unstable soils; or by reducing soil and vegetation disturbance from dragging logs.

B. Where groups of dwarf mistletoe or root rot disease infected trees need to be incorporated into the created opening to avoid infection of susceptible conifer reproduction, and their inclusion cannot be achieved by centering the created opening over the area of infection.

C. Where visual quality objectives require shaping and blending of openings to fit landform. This includes the visual rehabilitation of existing openings.

D. Where larger units are needed to achieve silviculture objectives in existing areas of regeneration cutting by the shelterwood method, and where destruction of the newly created stand of reproduction would occur as a result of delayed removal of shelter trees. This exception applies only to existing shelterwood units and shelterwood units under contract prior to approval of the Forest Plan.

2. Created openings will be separated by areas generally not classed as created openings. The areas between created openings shall contain one or more logical harvest units. These areas shall be large enough and contain a stand structure to meet resource requirements of the Forest Plan. Resource requirements may include wildlife habitat, watershed, landscape management, and others.

The total area of created openings contiguous to 30 acre or larger natural openings should normally be limited to an area not exceeding one-third the size of the natural opening, and not occupying more than one-third of the natural opening perimeter. Openings should not be created adjacent to any natural openings unless adequate vegetation along the edge can be developed or retained in sufficient density to protect wildlife values and scenic management objectives. The determination of adequate vegetation will be made by an appropriate interdisciplinary team.

3. A harvested area of commercial forest will no longer be considered a created opening for silvicultural purposes when stocking surveys carried out in accordance with Regional instructions indicate prescribed crop tree stocking at or above four and one-half feet in height and free to grow. Where other resource management considerations are limiting, such as wildlife habitat and visual requirements, a created opening will no longer be considered an opening when the vegetation in it meets the management prescription objective.

Utilization

Table IV-19

Utilization Standards for Saw Logs

Species(groups)	Min DBH 1/	Min Top DIB 2/
<u>First decade</u>		
Existing mature except lodgepole pine	9 inches	6 inches
Existing commercial thinning size and lodgepole pine	7 inches	4 inches
<u>Future decades</u>		
All species	7 inches	4 inches

DBH 1/ - Diameter at Breast Height
DIB 2/ - Diameter Inside Bark

1. Utilization will be emphasized as the primary means of disposal of waste wood residue.

Nursery Management

1. No special practice.

WATER

Planning

1. Program Implementation - Develop and annually update a Water Resource Five-Year Program that identifies support services, inventory needs, improvement targets, and monitoring direction by Unit and subdrainage. Coordinate the development and implementation of the program with other resource elements, Forests, and State and Federal agencies, Indian Tribes and public groups.

Improvement

1. Refer to the "Improvement" section under the soil resource for direction regarding the Watershed Improvement Program.

Administration and Management

1. Protection of Water Quality - Comply with State requirements for protection of waters of the State of Washington (Washington Administrative Code, Chapters 173-201 and 202) through planning, application, and monitoring of Best Management Practices (BMPs) in conformance with the Clean Water Act, regulations, and federal guidance issued thereto.

In cooperation with the State of Washington, the Forest will use the following process to insure protection of water quality:

A. Select and design BMPs based on site-specific conditions, technical, economic, and institutional feasibility, and the water quality standards for those waters potentially impacted.

B. Implement and enforce BMPs.

C. Monitor to determine if practices are correctly applied as designed.

D. Monitor to determine the effectiveness of practices in meeting design expectations and in attaining water quality standards.

E. Evaluate monitoring results and mitigate where necessary to minimize impacts from activities where BMPs do not perform as expected.

F. Adjust BMP design standards and application when it is found that beneficial uses are not being protected and water quality standards are not being achieved to the desired level. Evaluate the appropriateness of water quality criteria for reasonably assuring protection of beneficial uses. Consider recommending adjustment of water quality standards.

Use the existing agreed to process to implement the State Water Quality Management Plan on lands administered by the USFS, as described in Memorandum of Understanding (MOU) between the Washington Department of Ecology and U.S. Department of Agriculture Forest Service (7/79), and "Attachment A" referred to in this MOU (Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest 12/78).

Individual, general Best Management Practices are described in the General Water Quality Best Management Practices, Pacific Northwest Region, 11/88. This document provides guidance but not direction. Also included in this document is a description of the process, and limitations and use of these BMPs. Each general BMP listed includes the Title, Objectives, Explanation, Implementation and Responsibility, and Monitoring. Evaluations of the ability to implement and estimated effectiveness are made at the project level.

Normally, not all of the general BMPs listed will apply to any given project. There may be specific BMPs which are not represented by a general BMP in this document.

The sensitivity of the project determines whether the site-specific BMP prescriptions are included in the EA/EIS or in the sale/project plan, or in the analysis files.

For a more complete explanation of the above, refer to Appendix J in the FEIS, "Best Management Practices".

2. Management of Public Supply Watersheds - Municipal supply watersheds (See Glossary) will be managed to provide water at a level of quality and quantity which, with appropriate treatment by the purveyor, will result in a satisfactory and safe water supply, recognizing that watershed protection can supplement but not be a substitute for adequate treatment.

Conduct management activities in municipal supply watersheds so as to meet State Water Quality Standards for surface water. Achieve this goal through application of Best Management Practices, which will allow compatible multiple-use activities to be conducted on National Forest System Lands in these watersheds.

During project planning, identify any individual drinking water systems in the area that have a significant potential to be affected by proposed management activities. Identify requirements for protection of individual drinking water systems on a project level basis.

3. Water Resource Investigations - Evaluate the potential direct, indirect and cumulative effects of proposed activities on water resources. Refer to the Forestwide Standards and Guidelines for the soil resource for direction regarding cumulative effects analysis.

Design and conduct water resource inventories to support project analyses at a level commensurate with the planning issues. Develop a water resource inventory program, in cooperation with other resources to: (a) provide more specific information for area and project level analysis and planning, (b) improve the Forest data base for use in Plan revisions and (c) revise current inventories to a higher standard.

4. Monitoring - Monitoring and evaluation is contained in Chapter V and in Appendix F.

Rights and Use Management

1. National Forest Water Uses - Secure necessary water rights to accomplish the multiple-use objectives of the USDA-Forest Service as described by Federal law. For consumptive water uses: (a) Secure Federal reserved water rights pursuant to the

Reservation Doctrine and other enabling legislation or Executive Orders. (b) Acquisition of non-reserved water rights will be made pursuant to applicable State law.

For non-consumptive uses: (a) Assert Federal Reserved water rights for timber and watershed management, including instream flows sufficient to maintain stability of the stream channel for the purposes of securing favorable conditions of water flow and protecting against adverse impacts to productive timber lands adjacent to the channel, pursuant to authority contained in the Organic Administration Act of 1897. (b) Assert water rights for other resource programs by securing instream flows pursuant to authorities contained in other applicable Federal law.

2. Protection of Water Uses - Review water right claims and applications that involve development on or near National Forest System lands in order to determine compatibility with multiple-use objectives. Environmental analysis will be conducted by either the Forest or applicant to evaluate proposed water uses, diversions, transmission applications and renewal of permits on Forest.

Protection of water uses will be achieved through the following means: (a) filing protests with the State in cases where applications are made that adversely effect National Forest resources, (b) asserting claims under applicable Federal or State laws, (c) inserting protection measures into special use permits, (d) developing formal agreements over water use, or (e) purchasing needed water rights where sufficient water cannot be obtained under the Reservation or Appropriative Doctrines.

Permits will not be issued for occupancy of National Forest System lands if that occupancy would conflict with Reserved rights or interfere with meeting other multiple-use objectives of the USDA-Forest Service as described by Federal law.

SOIL

Planning and Inventory

1. Inventory- Maintain an accurate soil survey data base that is of sufficient detail and quality to meet Forest Planning needs. All new soil surveys will meet National Cooperative Soil Survey Standards.

2. Program Implementation - Develop and annually update a Soil Resource Five-Year Program that identifies support services, inventory needs, improvement targets, and monitoring direction by Unit and Subdrainage. Coordinate the development and revision of the Program with other resource elements, Forests, and State and Federal agencies.

Improvement

1. Inventory - Utilize the Forest Watershed Improvement Needs (WIN) Inventory for the identification and prioritization of treatment acres. Annually update the WIN inventory and project prioritization compatible with Regional guidelines.

2. Scheduling - Eliminate backlog of watershed improvement needs on a priority basis as directed by the Soil and Water Five-Year Programs. Acres involving potential threats to life and property will receive the highest priority for treatment, followed by projects in municipal watersheds and drainages that are used by anadromous fish. Calculate target accomplishment on a treated acre basis.

3. Maintenance - Provide maintenance to assure that watershed improvement projects are functional until objectives of the projects are met and to protect capital investments.

4. Monitoring - Watershed improvement projects and project maintenance will be monitored in order to evaluate project and program effectiveness.

Administration and Management

1. Cumulative Effects Analysis - In sub-drainages where project scoping identifies cumulative effects to be an issue or concern, a detailed watershed analysis will be made by an appropriate group of specialists. Their job will be to determine current watershed conditions and evaluate probable impacts for additional management activities. These studies will include all lands regardless of ownership.

Furthermore, a detailed watershed analysis will always be conducted when more than forty percent (40%) of the forested area in a 1,000 acre or larger subdrainage is projected to be in openings at one time (opening being defined as: the condition when the regeneration crop is less than fifteen feet tall).

2. Compaction, Displacement, Puddling, Severely Burned - Leave a minimum of 80 percent of an activity area in a condition of acceptable productivity potential for trees and other managed vegetation following land management activities. Surface soil conditions known to result in reduced productivity or loss of productive land surface are: detrimental compaction; detrimental displacement; detrimental puddling, and severely burned. The total acreage of all detrimental soil conditions should not exceed 20 percent of the total acreage within the activity area, including landings and system roads.

3. Soil Erosion - refers to both surface erosion and soil mass wasting.

a. Surface Erosion - to meet acceptable levels of soil loss and soil management objectives, the minimum percent effective ground cover following cessation of any soil-disturbing activity should be:

Table IV-20
Erosion Hazard Class

EROSION HAZARD CLASS	MINIMUM PERCENT EFFEC. GROUND COVER	
	1st Year	2nd Year
Low (very slight-slight)	20-30	30-40
Medium (moderate)	30-45	40-60
High (severe)	45-60	60-75
Very High (very severe)	60-75	75-90

(NOTE: see glossary for definition of effective ground cover).

b. Soil Mass Wasting - Evaluations of each occurrence will be made to determine the amount of sediment produced. Individual sub-drainages affected will be added to the monitoring plan.

4. There will be no scheduled timber harvest on stability Class V soils. These lands are unsuitable for timber management.

5. Soil and foliar testing (both pre and post application) should be done for all fertilization projects. This information will be used to determine the site specific application rates needed, and also to determine how long the fertilizer will last in different soils.

6. Closed roads, temporary roads, and landings should be placed in conditions to minimize soil erosion.

7. Surface water will be controlled on all roads, landings, rock pits, parking areas, and other road related facilities.

8. Where the above standards for soil erosion cannot be met because of specific site conditions, appropriate mitigation measures shall be devel-

STANDARDS AND GUIDELINES

oped in the project environmental analysis, documented in the project record, and implemented prior to fall rains.

9. Sites degraded by management activities shall be rehabilitated.

AIR

1. Maintain air quality at a level that is adequate for the protection and use of Forest resources produced on the Wenatchee National Forest, and meets or exceeds applicable Federal and State standards and regulations.

2. Protect Air Quality Related Values within all Class 1 areas.

3. Prescribed burning will be managed to comply with the State Smoke Management Plan administered by the Department of Natural Resources, the State Implementation Plan (SIP) developed and administered by the Department of Ecology, and the Final Environmental Impact Statement for the Pacific Northwest Regional Guide dated May 1984.

4. To meet Regional Standards and Guidelines, the Wenatchee National Forest will demonstrate reasonable progress in reducing total suspended particulates (TSP) from prescribed burning during Forest Plan implementation. The starting point for the Forest is 5,000 tons.

5. Prescribed fires that exceed applicable air quality regulatory standards will receive appropriate suppression action to minimize the impact to air quality.

MINERALS

Locatable, Leasable, Common Variety, and Recreational

1. The public's right to explore for, develop and produce mineral resources is recognized, and orderly mineral exploration, development and production activities shall be encouraged and facilitated in all areas which are available to such

activities or where valid existing rights to conduct such activities exist.

2. Process all notices of intent, plans of operation, lease applications and permit applications in a timely manner.

3. Approve reasonable means of access when needed for mineral prospecting, exploration and development activities.

4. Per a Coop-Agreement with the State of Washington, when appropriate coordinate mining plan evaluations with the Washington State Department of Natural Resources, Division of Geology and Earth Resources.

5. If mineral activity is proposed, ensure that the land status allows the proposed activity to be conducted (e.g., open to mineral entry under the 1872 mining law, open to and/or subject to mineral leasing and open to the disposal of mineral materials, etc). If the area is withdrawn, determine if valid prior existing rights exist before approving proposed activities (consult with the District, Forest or Area Mineral Specialists).

6. Administration of all locatable, leasable and salable mineral resource activities shall ensure that those activities are conducted in accordance with the 36 CFR 228 Regulations; are conducted in compliance with applicable Federal and State standards for air quality, water quality, solid waste disposal and treatment, threatened and endangered species, cultural resources, and fire; are appropriately integrated with the use, conservation and protection of all other resources; and so as, where feasible, to minimize adverse environmental impacts.

7. Ensure that an appropriate environmental analysis and documentation is used as a basis for making mineral leasing recommendations, approving proposed mineral-related activities; establishing reclamation objectives and requirements, for designing reasonable but necessary stipulations needed to protect other resources; and for establishing reasonable but appropriate bonding requirements.

Ensure that mineral leasing recommendations are made in compliance with the Federal Onshore Oil and Gas Leasing Reform Act of 1987, the Geo-

thermal Steam Act, the Acquired Lands Leasing Act, and other applicable laws and regulations. Once leases are issued, on-the-ground activities will be managed in-keeping with the Interagency Agreements between the Forest Service and the Bureau of Land Management.

8. To the extent practical limit recommended stipulations for leases and permits to only those that have appropriate and approved wording (i.e., Uniform Format For Oil and Gas Lease Stipulations--draft April, 1988 or other approved stipulations). These may include, but are not limited to the following:

1. No surface occupancy stipulation
2. Timing or seasonal stipulation
3. Controlled surface use stipulation

9. Ensure that approved mineral activities are reasonably necessary for and incidental to mineral exploration, development or production.

10. Periodically conduct compliance checks on approved mineral activities to ensure that they are being conducted in compliance with a lease, permit or approved operating plan.

11. If existing laws and regulations will not provide adequate protection of other resources and a withdrawal is determined to be necessary, ensure that the mineral resources are appropriately evaluated and the proposal for withdrawal is made in accordance with the requirements of the Federal Land Policy and Management Act of 1976 (FLPMA).

12. If other resource activities may interfere with the right to conduct mineral resource activities (e.g., exploration, development, mining, mining claim maintenance, etc.), determine what rights do exist. If conflicts exist, resolve the conflicts before proceeding with the proposed activity.

13. Avoid or minimize capital investments in or adjacent to areas with known reserves and alienated mineral rights. If a mining claim validity examination is determined to be necessary in order to resolve land use conflicts, consult with the Area Mining Specialist. Mining claim validity should be used as a last resort for resolving such conflicts.

14. Recreation panning, sluicing, dredging and rockhounding shall be allowed throughout the Forest where such activity does not conflict with established management objectives, withdrawal objectives or the rights of mining claimants. If warranted, management plans providing specific direction on how and where these activities can occur shall be implemented.

RURAL COMMUNITY AND HUMAN RESOURCES

Human Resource Programs

1. Utilize available human and community development programs and/or volunteers in the National Forests whenever they can efficiently accomplish Forest work.

Civil Rights Program

1. Maintain an Affirmative Action Plan.

2. Conduct compliance reviews as required by Title VI of the Civil Rights Act of 1964, within standards established by the Forest Service.

3. Make special efforts to inform the general public, including minorities and the underprivileged, of benefits they are eligible to receive from Forest programs. Techniques and the media best suited to increase awareness and participation will be used.

American Indian Coordination

1. National Forest lands will be managed to minimize social and administrative barriers to legitimate users of the Forest. Where common boundaries exist with the Yakima Indian Reservation, resource activities will be closely coordinated.

2. Honor trust responsibilities to the Yakima Indian Nation under the 1855 Treaty with the Yakimas (12 Stat. 951, June 9, 1855).

3. Where appropriate, information about planned project activities will be presented to Native American Indian groups for coordination concerning effects on traditional religious sites.

STANDARDS AND GUIDELINES

4. Protect for Native Americans their access to sites, use, and possession of sacred objects, and the freedom to worship through ceremonial and traditional rites. Appropriate protection of these areas will be coordinated with the religious leaders of the Yakima Indian Nation and the Confederated Tribes of the Colville Reservation.

LANDS

Special Use Management

1. Land use requests will be reviewed for compatibility with Forest plan prescriptions and allocations.
2. Terminate or conform noncompatible uses on an opportunity basis.
3. Where a use can be accommodated on private or other land, National Forest land will not be used.
4. Private uses will generally be on a charge basis, whereas use by other public agencies will usually be without charge.
5. Management practices/prescriptions will not be applied which restrict or interfere with the current use of transportation/utility corridors.
6. New transportation/utility proposals should be accommodated within existing corridors to the maximum extent feasible.

Right-of-Way Grants for Roads and Trails

1. Aggressively acquire all needed access, in advance of project activity such as the sale of timber.
2. With few exceptions, unlimited easements granted in perpetuity will be acquired.
3. Limited easements (i.e., those authorizing administrative use, but not public use) will be acquired only when, for resource management or other reasons, public use is not desirable or necessary.

4. Temporary easements will be used under the conditions defined in the Forest Service Manual.

Property Line Location, Property Boundary, and Corner Maintenance

1. Property line survey, marking, and posting will be accomplished in the following order:
 - A. Lines needed to facilitate resource projects will be done first.
 - B. Lines involved in litigation, potential litigation or trespass or potential trespass will have priority for non-project oriented work.
2. As much property line as possible should be surveyed, marked, and posted on a cooperative basis with neighboring landowners. This work may be done by our Forest surveyor, or by a "third party" Washington State licensed surveyor acceptable to both the cooperator and the Forest.

Encroachment

1. Prevent the occurrence of occupancy trespass through accurate, clear survey marking and posting of property lines. Where possible, this will be done in cooperation with the neighboring property owners.
2. Where appropriate, the "Small Tracts Act" will be applied in the reduction of "backlog" cases and in resolving new trespasses which occur in "good faith" situations.
3. Promptly detect and act on "new" cases.

Landownership Planning, Land Adjustment Planning, and All Adjustment Activities

1. Landownership Classification on the Wenatchee National Forest places lands in one of five categories. The direction for each is:

Category I lands are those within congressionally designated areas; for example, a Wilderness. The direction for this category is to retain existing National Forest lands and acquire private inholdings.

Category II lands are those within administratively designated areas; for example, scenic areas, Mather Memorial Parkway, botanical areas, and other lands which have been determined to be necessary for wildlife, visual, or recreation needs. Generally, in this category existing National Forest lands will be retained and private inholdings will be acquired. Acquisition of private lands in this category will be pursued as opportunities arise.

Category III lands are primarily within land allocations where management direction emphasizes commodity production. The direction for this category is to avoid placing priorities on either retention or disposal of lands. Ownership changes in either direction may be appropriate. They will be considered on a case-by-case basis.

Category IV lands are National Forest lands which will serve the public interest best in private ownership and existing private lands which should remain in private ownership. The direction for this category is to transfer the National Forest lands into private ownership. The preferred method for accomplishing this is land exchange, thus advancing other land management goals at the same time. Examples of lands which fit this classification are:

- A. Isolated small parcels of land which are impractical to manage.
- B. Parcels where a greater general public value can be derived in private ownership.
- C. Areas necessary for community expansion.

Category V lands are those which require an intensive study before priorities for ownership can be recommended. The direction for this category is to initiate the necessary studies at the earliest opportunity.

In addition to the above, communications will be maintained with neighboring Federal land management agencies. This will be done with the view of affecting land transfers to improve both agencies' resource management.

Rights-of-Way, Cost Share Agreements

1. Use cost share agreements to avoid economic and resource impacts associated with duplicating existing or planned road systems.

FACILITIES

Transportation System Planning and Inventory

1. State and Federal Highways

The Regional Forester's Memorandum of Understanding with Washington State will be consulted for standards and guidelines for coordinating the location, construction, maintenance, signing, access and control, third-party occupancy, landscape management, rest areas, right-of-way grants for existing highways, and Forest highway coordination. This Memorandum is included in this Management Plan by reference.

2. County Roads

- a. When the majority of the use on Forest development roads is comprised of public service or other non-Forest Service generated traffic from commercial or residential development, or the road is used for mail, school, or other local government purposes, the Forest Service will actively negotiate and encourage the transfer of its jurisdiction to the appropriate public road agencies. This is usually a county.
- b. Continue to cooperate with counties and share in the cost of construction, reconstruction, improvement, and maintenance of certain Forest development and county roads. Existing agreements that provide standards and guidelines for consultation, maintenance, rights-of-way, etc., are included in this plan by reference.

3. Share Cost Roads

Whenever possible or feasible, the Forest Service will avoid duplicating existing or planned road systems by negotiating agreements with interested parties to share in the costs of a single system to serve all tributary ownerships. All existing agreements with Burlington Northern, Plum Creek,

STANDARDS AND GUIDELINES

Boise Cascade, Idaho Pine, Longview Fibre, and the Washington State Department of Natural Resources will be reviewed. Future agreements and supplements will insure that the tributary areas and volumes are in conformance with the prescriptions in this Management Plan. When they are adjusted and verified, they shall be included in the Plan by reference.

4. Forest Development Roads

Forest development roads are not public roads in the same sense as roads that are under the jurisdiction of public road agencies, such as States or counties. Forest development roads are not intended to meet the transportation needs of the public at large. Instead, they are authorized only for the administration and utilization of National Forest System lands. Although generally open and available for public use, that use is at the discretion of the Secretary of Agriculture. Through authorities delegated by the Secretary, the Forest Service may restrict or control use to meet specific management direction. Commercial users, permittees, or contractors also may be required to share in the cost of developing, improving, and maintaining forest development roads.

These are roads under the jurisdiction of the Forest Service which are necessary for the protection, administration, and utilization of the National Forest system, and the use and development of its resources (Title 23, USC 101, as amended by the Surface transportation Act of 1978).

Road Construction

1. Roads will be designed and constructed as stable and durable structures suitable for their intended use. Design elements and standards shall be selected to meet the criteria developed from land and resource plans. Standards for timber sale roads included in the contract as specified must comply with the Forest Service Manual. Deviations from standards must be justified and attested to in writing by the Forest Engineer as being technically adequate to meet management's objectives.

2. Plan and design temporary roads to re-establish vegetative cover on the disturbed area within a reasonable period of time, not to exceed 10 years after the termination of a contract, lease or permit, unless the road is determined necessary as a permanent addition to the National Forest Transportation System.

Road Reconstruction

1. Reconstruction of roads will be limited to the requirements necessary to provide for the intended uses and to protect adjacent resources.
2. Roads that do not meet standards may be operated without reconstruction providing the safety of users and the stability of the road can be otherwise provided. Minor reconstruction is authorized for spot repairs. Restrictions on public use for the duration of the project will be considered before more extensive reconstruction is authorized.

Road Operation

1. Road Closures- The decision to close any Forest road will be made on a case by case basis. Unless there is a resource need documented in the project analysis, currently open roads will remain open and newly constructed roads will be closed to public access by vehicle.

Fire, Administration, and Other (FA&O) Construction/Reconstruction

1. Facility project needs will be developed through site plan analysis, evaluated through the NEPA process and selected by using Regional FA&O criteria. Condition surveys will be performed annually with health and safety factors having high priority.
2. Consider the special needs of handicapped persons for employment opportunities, and in the design of public facilities.
3. Facilities should be planned, developed, and maintained and operated for safe use, support of the Forest resource programs, and cost effectiveness.

4. Buildings and utility systems construction and reconstruction, additions and changes, shall comply with approved site development plans.

5. The Administrative facilities management priorities are:

- A. Public and employee safety and health
- B. Prevention of site and interior and exterior building deterioration
- C. Energy conservation
- D. Minor improvements

6. Provide and manage administrative facilities sufficient to accomplish land and resource management and protection objectives of the Forest. Prepare administrative site development plans for all Forest administrative sites. Long-term development and maintenance costs will be a consideration in facilities planning.

PROTECTION

Fire Management Planning and Analysis

1. All wildfires will receive a prompt suppression response. Appropriate suppression strategies will include Control, Contain, and Confinement actions.
2. Priorities for protection will first be human life, followed by public safety and improvements.
3. If a fire escapes Initial Attack, an Escaped Fire Situation Analysis will be completed and approved by the responsible line officer. Efficiency will be emphasized.
4. The prevention of human caused wildfires will continue to be a management priority. The investment in this program will be commensurate with the values at risk.
5. Prescribed fire will be used to modify vegetation in an effort to minimize the risk of wildfires. Unplanned ignitions may be utilized if a prescribed fire plan has been developed and it is appropriate to the management area affected.

6. Prescribed fire will also be used as a resource management tool when appropriate planning indicates it is an efficient and effective option to implement. A prescribed fire that escapes is a wildfire and will receive an appropriate suppression response.

7. Develop and maintain preattack facilities in coordination with the management objectives of each specific management prescription.

Law Enforcement

1. Maintain cooperative law enforcement agreements with Chelan, Kittitas, and Yakima Counties.

Forest Pest Management

1. Survey stands for early detection of pest problems.
2. Coordinate with the Regional Forest Pest Management Unit for technical assistance.
3. Pesticide application will conform with EPA regulations and label restrictions, and will be made only after site specific evaluations have been made.
4. Utilize integrated pest management strategy to prevent unacceptable resource damage and to meet resource objectives in an economically efficient manner.
5. Manage timber to create conditions favorable for the prevention of pest damage.

RESEARCH NATURAL AREAS

1. Normal management and protection activities within RNA's are the responsibility of the Forest Supervisor. Scientific and educational uses of RNA's are the responsibility of the Pacific Northwest Forest and Range Experiment Station. Extensive research use requires a cooperative agreement between the user and the Forest Service. The Forest Supervisor and District Ranger administering the affected Research Natural Area will be informed of mutually agreed

upon activities by the Experiment Station Director. However, a scientist should visit the administering Ranger Station when beginning the studies and explain the nature, purpose, and duration of the activities. Permission for brief visits to Research Natural Areas for observational purposes can be obtained from the District Ranger. Management practices should not call attention to these areas.

BIODIVERSITY

1. Maintain or enhance biological diversity by providing or developing an ecologically sound distribution and abundance of plant and animal communities and species at the forest stand, subdrainage and Forest level. This distribution must contribute to the goal of maintaining or enhancing all native and desirable introduced species and communities.

2. Evaluate opportunities to maintain or enhance stand, subdrainage and Forest level components of biological diversity on a project by project basis as commensurate with management area direction. This evaluation will include project effects on the diversity (both visual and biological) and on wildlife and plant habitat in the subdrainage. If the project will reduce any of these components below the acceptable level as indicated by the management objectives for the sub-drainage the project may be altered to maintain diversity, or wildlife and plant habitat.

3. During project planning, areas of exceptional aesthetic value, unique wildlife or plant habitat or that contribute needed components for biological diversity may be found. These areas can be proposed through the District Ranger to the Forest Supervisor for inclusion into a prescription, special interest area or Research Natural Area (in consultation with the regional RNA committee) to preserve the appropriate area or forest ecologist and appropriate specialists will decide whether to amend the forest plan to allow a change in prescription (or classification) of the area in question. The Supervisor could also decide to protect the area until the next plan revision.

4. The most critical components of diversity (because they are relatively uncommon) include old growth and wildlife and plant habitat for rare species. Visual diversity is also an important consideration in project planning. Old growth stand in particular will often be important in the maintenance of biological diversity and aesthetic value.

Retain contiguous forest stands of later seral stages within 3rd and 4th order watersheds. Link patches of later seral stages with corridors of mid to late seral stages, such as riparian or visual corridors.

Identify subdrainages specific management objectives for fish and wildlife habitat and plants. These objectives should maintain or develop the habitat sizes, patterns and spacing essential for allowing genetic interchange and movement of species.

Where mature and old growth forest stands are managed for wildlife habitat, select and manage for stand characteristics and spatial location and size that will ensure viability of all plant and animal species closely associated with those habitats.

5. During project planning, develop site specific management prescriptions that meet objectives for biological diversity and ecosystem function. In addition to other management direction, consider the following guidelines:

Commercial forest management should provide for species diversity.

Tree species used in planting harvested units should be selected by considering site potential as indicated in plant association guides. Whenever appropriate a mixture of trees species should be planted.

Commercial and non-commercial thinning guidelines will incorporate the species diversity concept.

Vegetation management should allow for all natural species to function. None should be eliminated from the site.

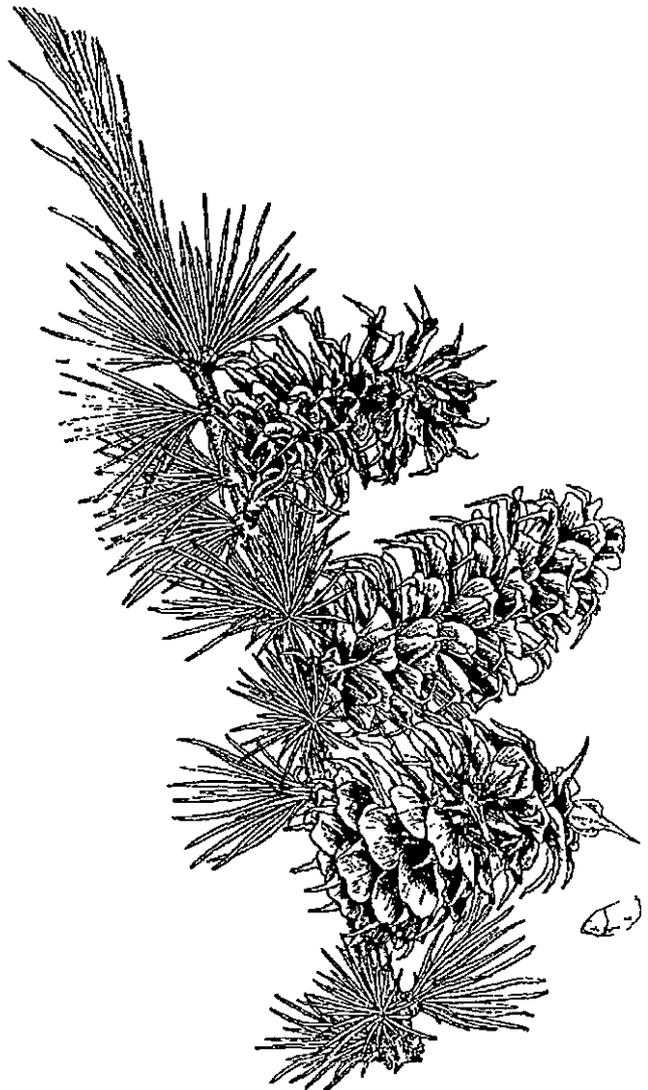

F. MANAGEMENT PRESCRIPTIONS

The National Forest land within the Wenatchee National Forest has been divided into 24 management areas, each with different management goals, resource potential, and limitations. The management areas are shown on the accompanying map, which can be used for reference. The management area maps of record consist of a set of larger scale maps on file in the Forest Supervisor's Office.

Boundaries of the management areas are not meant to require a ground survey for their placement. The actual placement on the ground for management purposes may vary a few hundred feet from the location on the map depending on the circumstances of the project. Disputes that arise will be handled on a case-by-case basis.

Objectives shown represent minimum levels, higher objectives may be achieved.

Table IV-21 displays the acreage of the various management areas.

**TABLE IV-21
MANAGEMENT AREA ACREAGES**

MANAGEMENT	AREA	ACRES
EF-1	Experimental Forest	4,770
EW-1	Key Deer and Elk Habitat	118,742
EW-2	Riparian-Aquatic Habitat Protection Zone	47,361
EW-3	Key Big Game Habitat	19,059
GF	General Forest	389,087
MP-1	Mather Memorial Parkway	13,717
OG-1	Old-Growth Management (dedicated)	79,840
OG-2	Mature Habitat (managed)	49,015
RE-1	Developed Recreation	6,021
RE-2a	Dispersed Recreation, Unroaded Motorized (w/o 4x4 routes)	79,607
RE-2b	Dispersed Recreation, Unroaded Motorized (w/ 4x4 routes)	16,748
RE-3	Dispersed Recreation, Unroaded Non-motorized	116,092
RE-4	Dispersed Recreation, Unroaded, Timber Harvest	6,614
RM-1	Range Management	17,702
RN-1	Research Natural Areas	2,247
SI-1	Classified Special Areas - Scenic and/or Recreation	70,512
SI-2	Classified Special Areas - Other	2,798
ST-1	Scenic Travel - Retention	83,635
ST-2	Scenic Travel - Partial Retention	174,880
UC-1	Utility Corridors	1/
WI-1	Wilderness	841,034
WS-1	Scenic River (Proposed)	5,554
WS-2	Recreational River (Proposed)	11,363
WS-3	Wild River (Proposed)	23,426 2/
Water		7,780

1/ Acres are distributed among other management areas adjacent to utility corridors

2/ All but 170 acres are within Wilderness

Individual Prescriptions

The following are the individual management area prescriptions which apply to the acreage shown in Table IV-21. They must be used along with the "Forest-wide" standards and guidelines.

MANAGEMENT PRESCRIPTION EF-1

TITLE: Experimental Forest

GOAL STATEMENT: Provide opportunities to study the effects of Forest management and fire on vegetative, soil, and water resources occurring on the east side of the Cascade Mountains. Maintain the area in a form that will not compromise the opportunities for research.

DESCRIPTION: The Entiat Experimental Forest was designated under the authority of the Chief of the Forest Service in 1970. Burned by wildfire in 1970, and rehabilitated and reforested in subsequent years, the area has been the subject of numerous scientific investigations. Currently the Experimental Forest is being managed for a wide range of multiple uses in coordination with the Forestry Sciences Laboratory in Wenatchee. Periodic monitoring will occur until vegetation reaches such a size as to have a significant effect on water production. New studies will be initiated at that time.

Objectives following the Entiat Burn in August 1970 were to study the effects of fire on complete hydrologic units.

Implement fire suppression strategies that attempt to protect the unique research values specific to each research natural area</p> <p>2 Fire suppression tactics should be implemented that attempt to protect the experimental nature of these areas</p> <p>1 Treatment of both activity generated and natural fuels is appropriate when coordinated with the specific experimental activities of the area Coordination with the Experiment Station project leader is essential</p> <p>1 Develop only those preattack facilities which support the objectives of the experimental forest</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-103</p> <p>1 Insect and disease outbreaks should be suppressed when studies are threatened and /or unacceptable damage to resources would occur if no controls are applied</p> <p>2 Research should develop and/ or follow sound Integrated Pest Management (IPM) principles</p> <p>3 Utilize IPM strategies to prevent unacceptable pest damage and meet resource objectives</p> <p>4 Coordinate all activities with the Experimental Station Project Leader during planning and implementation of project.</p>	

MANAGEMENT PRESCRIPTION: EW-1

TITLE: Key Deer and Elk Habitat

GOAL STATEMENT: *Manage deer and elk winter range to meet habitat requirements for sustaining optimum carrying capacity.*

DESCRIPTION: Deer and elk winter ranges are generally on the edge of the Forest, adjacent to or intermingled with, other land ownerships, at low elevations, south and/or east facing slopes with reduced snow depth and early melt-off of snow. Because of these conditions these areas are highly desired for winter and/or early spring recreation activities and dry out early to become high fire danger areas. These habitats have openings covering 10 to 60 percent of the area (used by big game for foraging), containing shrubs, grasses, and forbs with scattered conifer trees, and 20 to 80 percent covered by conifer stands (used by big game for cover). The quality of the forage and the amount of thermal cover combined with the amount of human disturbance are the factors that determine the carrying capacity of these areas for big game in winter.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
RECREATION	Recreation Planning and Inventory	1 Visual Quality Objective MODIFICATION	1. Coordinate with the Washington Department of Wildlife to identify biological objectives
		2 Manage in a Semi-Primitive Non-Motorized to Roaded Modified Recreation Opportunity Spectrum	
	Cultural Resource Evaluation, Assessment and Protection	1 Forest-wide Standards and Guidelines apply. See p IV- 66	
	Facility and Site Reconstruction and Construction	1 Construction and reconstruction of facilities will be designed to minimize impacts on big game.	
	Facility and Site Management	1. Forest-wide Standards and Guidelines apply See p. IV- 68	
	Use Administration	1. Motorized access will be managed when and where needed to meet biological objectives	
	Trail Reconstruction and Construction	1 Construction and reconstruction of trails will be designed to minimize impacts on big game.	
Trail System Maintenance and Operation	2. As opportunities become available, build trails to view big game where appropriate.		

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p>	<p>1 Develop optimum cover/forage relationships for each Species Management Guide</p> <p>2 Big horn sheep requirements will take precedence over deer or elk management, where sheep are present or where sheep habitat exists</p> <p>3 Activities in deer and elk winter range will be limited to corridors for access to other areas from December 1 to April 15 Activities are defined as any human movement that causes the animals distress (i.e., snowmobiling, x-country skiing, rock or ice climbing, hunting, hiking, logging, road building, motorcycle riding, 4-wheel driving etc.) Habitat improvement activities are excluded</p> <p>4 Activity closures earlier than December 1 or later than April 15, may be established by District Rangers for each big game management area in cooperation with the Washington Department of Wildlife</p> <p>5 Restrict activities to allow big game to fully utilize habitat</p> <p>6 Winter range, north of the Wenatchee River, will be managed for deer</p> <p>7 Winter ranges will be managed in cooperation with Washington Department of Wildlife to reduce damage to neighboring private lands</p> <p>8 Manage primary cavity excavators at 60 percent of the potential population level</p>	<p>1 In wildlife habitats in managed forests, optimum cover is 40% and optimum forage is 60%</p>
	<p>Non-Structural Habitat Improvement</p>	<p>1 Use all available techniques for habitat improvements</p> <p>2 Habitat improvements will be done to increase big game carrying capacity and provide more flexibility for timber management</p>	<p>1 The optimum objective for habitat effectiveness index for deer and elk will be 80 Areas that cannot be managed at that level will be managed for the highest level possible</p>
	<p>Structural Habitat Improvement</p>	<p>1 Habitat improvements will be done to increase big game carrying capacity and provide more flexibility for timber management.</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>TIMBER</u></p>	<p>Regeneration Harvest</p>	<p>1. Use harvest methods compatible with the goal to maintain or improve habitat</p>	<p>1 Plant all non-stocked areas following regeneration harvest to achieve habitat effectiveness objectives Use genetically superior stock as available</p> <p>2 Protect plantations against animal damage to achieve habitat effectiveness objectives.</p> <p>1. Precommercially thin to achieve habitat effectiveness objectives</p> <p>1 The optimum objective for habitat effectiveness index for deer and elk will be 80 Areas that cannot be managed at that level will be managed for the highest level possible</p> <p>1 Cone collection</p> <p>2 Seed certification.</p>
	<p>Intermediate Harvest</p>	<p>1 Allow commercial thinning that will maintain at least 40 percent thermal cover and 10 percent hiding cover</p>	
	<p>Silvicultural Examination and Prescription</p>	<p>1. Make stand examinations prior to any activity.</p> <p>2 Design silvicultural prescriptions to meet big game needs</p>	
	<p>Reforestation</p>	<p>1 Reforestation will be aimed at achieving sustained optimum cover/forage relationships</p>	
	<p>Timber Stand Improvement</p>	<p>1 Thin to provide optimum cover/forage relationships</p>	
	<p>Timber Sale Preparation and Timber Harvest Administration</p>	<p>1 The environmental analysis will address big game issues</p> <p>2 Created openings will be considered closed when tree heights are 6 feet tall in deer areas and 8 feet tall in elk areas</p> <p>3 A habitat effectiveness analysis will be done immediately before, immediately after, and ten years after project.</p> <p>4. Activities will avoid conflicts with winter, spring, and fall use by big game</p> <p>5 Timber harvesting or road building activities will be scheduled to avoid conflicts with big game fawning and calving</p>	
	<p>Nursery Management</p>	<p>1. Perform as required to meet reforestation program needs including allowance for natural disasters.</p>	
	<p>Genetic Tree Improvement</p>	<p>1. No special practice.</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>WATER</u></p>	<p>Planning</p>	<p>1. Forest-wide Standards and Guidelines apply See p. IV- 94</p>	
	<p>Improvement</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV-94 and 96</p>

<p><u>AIR</u></p>	<p>Planning</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 98</p>	
	<p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 98</p>	
<p><u>MINERALS AND GEOLOGY</u></p>	<p>Locatable Minerals</p>	<p>1 If reasonable, during pre-production stages recommend mineral prospecting, exploration and development activities be conducted during other than the critical use seasons (i e., critical winter, spring and fall use periods).</p>	
	<p>Leasable Energy Minerals</p>	<p>1 Recommend stipulations be attached to leases and permits which reasonably restricts pre-production activities during the critical use season</p>	
	<p>Common Variety Minerals</p>	<p>1 Same as for Locatable Minerals above.</p>	
	<p>Recreational Mineral Activities</p>	<p>1 If the activity would significantly affect big game use of the area during the critical use season do not approve it</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RURAL COMMUNITY AND HUMAN RESOURCES</u></p>		<p>1 Forest-wide Standards and Guidelines apply See p IV-99 and 100</p>	
<p><u>LANDS</u></p>	<p>Special Use Management</p> <p>Right-of-Way Grants for Roads and Trails</p> <p>Federal Energy Regulatory Commission License and Permits</p> <p>Property Line Location Property Boundary and Corner Maintenance</p> <p>Landownership Planning, Land Adjustment Planning, and All Adjustment Activities</p> <p>Rights-of-Way, Cost-Share-Agreements</p>	<p>1 Utility corridors are permitted subject to determination of need and requirements necessary to protect key big game habitat</p> <p>2 Manage special uses to maintain the goals of the Species Management Guide</p> <p>1 Grant necessary road/trail access to landlocked inholders, but keep public access to a minimum during winter, spring, and fall</p> <p>1 Recommend only compatible uses</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-100</p> <p>1 National Forest or Washington Department of Wildlife ownership of winter range areas is preferred</p> <p>1 Big game needs will be resolved during negotiation of cost share agreements</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>FACILITIES</u></p>	<p>Road Construction</p>	<p>1 Construct the least amount of the lowest standard road necessary to accomplish the project objectives</p>	<p>1 Screen meadows, clearcuts, and other openings with vegetation or topography</p>
	<p>Road Operation</p>	<p>1 Emphasize road closures to reduce impact on wildlife</p> <p>2 Prohibit or eliminate road use inconsistent with wildlife goals</p> <p>3 Restrict operating season when necessary to reduce impact on wildlife</p>	<p>2 Do not block elk and deer migration routes with road cuts and fills</p> <p>3 Where roads cross elk and deer migration routes, use minimum clearing and sight distance</p> <p>4 Locate roads so that they may be closed</p> <p>5 Avoid straight sections of road of more than 1/4 mile.</p> <p>6 Fall only those snags that present a safety hazard</p> <p>7 To the extent practical, avoid the disturbance of cliffs, caves, talus, and other limited habitats</p> <p>8 To the extent practical, avoid locating roads in migration routes, saddles, gaps, bands around ridges, streams, seeps, and springs, and cover areas that are in locations generally deficient in cover</p> <p>9 To the extent practical, wind-row or pile slash to provide cover</p> <p>10 Provide openings in wind-rowed, piled, scattered slash at all known wildlife crossings and at a minimum of every 100 feet</p>
	<p>FA&O Construction and Reconstruction</p>	<p>1 To the extent practical, avoid construction in these areas</p> <p>2 Consider removing any facility not compatible with wildlife goals</p> <p>3 Structures intended to benefit wildlife or facilitate management of wildlife permitted</p>	<p>1. (See the Forest-wide standards and guidelines for wildlife and Fish)</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>PROTECTION</u></p>	<p>Fire Prevention</p>	<p>1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan</p>	
	<p>Fire Suppression</p>	<p>1 Implement fire suppression strategies commensurate with the habitat management objectives</p> <p>2 All fire suppression tactics and resources may be appropriate</p>	
	<p>Fire Hazard Abatement</p>	<p>1 Treatment of both natural and activity generated fuels is appropriate when consistent with the habitat management objectives of the specific area</p>	
	<p>Preattack Facilities Development</p>	<p>1 Develop preattack facilities in coordination with the habitat management objectives of each specific area</p>	
	<p>Law Enforcement</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-103</p>	
	<p>Forest Pest Management</p>	<p>1. Suppress insects and diseases when necessary to protect resource values</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives.</p>	

MANAGEMENT PRESCRIPTION: EW-2

TITLE: Riparian-Aquatic Habitat Protection Zone

GOAL STATEMENT: Maintain and enhance riparian management areas to perpetuate their distinctive resource values to (a) achieve and maintain habitat conditions necessary to maximize long-term natural production opportunities for desired fish species, (b) maintain water quality that meets or exceeds State Standards and (c) provide diverse wildlife habitat.

DESCRIPTION: This prescription applies to the land and vegetation adjacent to Class I, II and fish bearing Class III streams, lakes and wetlands. The Riparian Management Area (RMA) shall correspond to at least the recognizable area dominated by riparian vegetation (true Riparian Zone) and sufficient adjacent area (influence area) to assure adequate protection to achieve riparian management objectives and standards in the subdrainage. The area of consideration, from both banks of fish bearing streams and the perimeter of lakes and wetlands, is as defined in the variable width table found in the Forest-wide Riparian Standards and Guidelines

Riparian Management Area boundaries and specific riparian management objectives will be established for all projects within an RMA. Riparian management objectives will be established based upon analysis of RMA habitat conditions, objectives and standards both within the subdrainage (generally 1,000-10,000 acres) and at the project site.

Within Riparian Management Areas, management decisions will be made in favor of riparian dependent resources (water quality, fish and wildlife habitat) when conflicts exist with man's use.

Refer to the Forestwide Standards and Guidelines for Riparian Areas for overall direction on the planning and administration of management activities in RMAs. Refer to the "Administration" section in the Forest-wide Standards and Guidelines for Riparian Areas for a discussion of the use and refinement of applicable quantitative standards.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
RECREATION	Recreation Planning and Inventory	1 Forest-wide Standards and Guidelines apply. See p. IV-65 and 66 2. New developed recreation sites or expansions to existing sites will not reduce flood storage or routing ability and will minimize conflicts with Riparian dependent resources. All new projects will consider Riparian management objectives.	1 Range of Visual Quality Objectives (VQO) from Retention to Modification. The VQO applied will be dictated by the adjacent visual resource prescription and will be managed compatible with the goal of this Riparian Aquatic Protection Zone 2. Allow dispersed sites when compatible with the goal and Riparian Standards
	Cultural Resource Evaluation and Assessment	1 Forest-wide Standards and Guidelines apply See p. IV-66	1. Extraordinary measures may be needed in this zone due to hydraulic actions. Measures may include bank stabilization or cultural resource salvage
	Cultural Resource Protection	1. Forest-wide Standards and Guidelines apply See p. IV-66	Authorized excavation of cultural resources shall be conducted in a manner which best maintains riparian habitat and include necessary rehabilitation measures

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u> (continued)</p>	Facility and Site Reconstruction	1 Forest-wide Standards and Guidelines apply See p IV-67 and 68	1 When feasible relocate camp units outside the zone
	Facility and Site Construction	1 Forest-wide Standards and Guidelines apply See p IV-68	1 New sites will not be built in the floodplain
	Facility and Site Management	1 Forest-wide Standards and Guidelines apply See p IV-68	
	Use Administration	1 The Recreation Opportunity Spectrum applied will be dictated by the adjacent prescription	
	Trail Reconstruction	1 Forest-wide Standards and Guidelines apply See p IV-68	
	Trail Construction	1 Forest-wide Standards and Guidelines apply See p IV-68 and 69	1 To the extent practical locate and relocate trails outside of the Riparian/Aquatic protection zone 2 New trails, except for interpretative trails or those designed specifically to access Riparian resources should not be built within the RMA's
	Trail System Maintenance and Operation	1 Forest-wide Standards and Guidelines apply See p IV-69	
<p><u>WILDLIFE AND FISH</u></p>	Wildlife Surveys and Plans	1 Forest-wide Standards and Guidelines apply See p IV-80 through 83	
	Habitat Improvement	1 Forest-wide Standards and Guidelines apply. See p IV-83 and 84	
	Administration and Management	1 Forest-wide Standards and Guidelines apply See p IV-85 through 88	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RANGE</u>	Range Planning and Inventory	1 Forest-wide Standards and Guidelines apply See p IV- 88 and 89	1 Grazing will be permitted in the RMA when compatible with the RMA objectives 2 Management of the range resource will feature an intensive scheme 3 Allotment management plans will be designed to maintain or enhance riparian habitat Allotment plans will establish riparian habitat objectives and if conditions are not meeting objectives establish a schedule for recovery. 4 Use forage species which will enhance the riparian management area
	Range Non-Structural Improvements	1. Forest-wide Standards and Guidelines apply. See p IV-89 and 92	1 Improvements will be allowed when compatible with riparian management objectives and include provisions to maintain / improve habitat
	Range Structural Improvements	1 Forest-wide Standards and Guidelines apply See p IV-89	
	Range Structural Improvement Maintenance	1 Forest-wide Standards and Guidelines apply See p. IV-89	
<u>TIMBER</u>	Regeneration Harvest	1 Forest-wide Standards and Guidelines apply See p IV-92	1 Adjust harvest for specific goals in individual Riparian Zones to meet forest-wide riparian standards. 2. Maintain trees providing bank stability
	Intermediate Harvest	1 Forest-wide Standards and Guidelines apply See p IV-92	1 Salvage will generally be discouraged Review any such harvest to insure consistency with RMA objectives.
	Silvicultural Examination and Prescription	1. Forest-wide Standards and Guidelines apply See p IV-92	
	Reforestation	1 Forest-wide Standards and Guidelines apply See p IV-92 and 93	
	Timber Stand Improvement	1 Forest-wide Standards and Guidelines apply See p. IV-93	1. Allow precommercial thinning when consistent with management objectives in the subdrainage

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p>TIMBER (continued)</p>	<p>Timber Sale Preparation and Timber Harvest Administration</p> <p>Nursery Management and Genetic Tree Improvement</p> <p>Reforestation Animal Control</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV-93 and 94</p> <p>1. No special practice.</p> <p>1 Forest-wide Standards and Guidelines apply See p. IV-92 and 93</p>	<p>1 Give special emphasis to administration within the zone</p> <p>2 Directionally fall timber away from water courses unless such work is prescribed as a habitat improvement measure</p> <p>3 Protect snags from all incompatible uses.</p> <p>4 Remove convertible products (e.g firewood) only from designated areas</p>
<p><u>WATER</u></p>	<p>Planning</p> <p>Improvement</p> <p>Administration and Management</p> <p>Rights and Use Management</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV-94</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-95 and 96</p>	
<p><u>SOIL</u></p>	<p>Planning and Inventory</p> <p>Improvement</p> <p>Administration and Management.</p>	<p>1. Forest-wide Standards and Guidelines apply. See p IV-96</p> <p>1 Forest-wide Standards and Guidelines apply. See p IV-96</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-97</p>	<p>1. Maintain slope stability in and adjacent to the riparian management area.</p> <p>The minimum distance for RMA consideration is 100 foot horizontal distance from the ordinary high water line associated with both banks of streams and the perimeter of lakes and wetlands.</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>AIR</u>	<p>Planning</p> <p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-98</p> <p>1 Forest-wide Standards and Guidelines apply See p. IV- 98</p>	
<u>MINERALS AND GEOLOGY</u>	<p>Locatable Minerals</p> <p>Leasable Energy Minerals</p> <p>Common Variety Minerals</p>	<p>1 If a mineable deposit does not underlie this zone and if it is reasonable, limit significant surface disturbing activities to areas outside the Riparian-Aquatic zone</p> <p>2 Establish reasonable reclamation requirements in approved operating plans that ensure the riparian habitat is reasonably restored or complemented</p> <p>3 If the area is identified as water and associated wetlands as defined in 33 CFR 328, unless categorically exempted by 33 CFR 323.4, ensure dredging activities are conducted in compliance with section 404 of the Clean Water Act and a Corps of Engineers permit is obtained</p> <p>1 If reasonable, attach stipulations to a lease that require significant surface disturbing activities to be conducted outside of the Riparian-Aquatic zone.</p> <p>1 If removal would significantly impact the Riparian-Aquatic zone and reasonable reclamation is not achievable, do not permit the removal of these mineral resources</p> <p>2 Establish reasonable reclamation objectives which either restore the habitat or complement it.</p>	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		<p>1 Forest-wide Standards and Guidelines apply See p IV-99 and 100</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>LANDS</u></p>	<p>Special Use Management</p>	<p>1 Utility corridors are permitted subject to determination of need and requirements necessary to protect the riparian resource Include measures to minimize or mitigate resource damage, where permitted</p>	<p>1 Retain National Forest lands and acquire private inholdings on an opportunity basis</p>
	<p>Right-of-Way Grants for Roads and Trails</p>	<p>1 Grant access only where no other feasible options exist. 2 Relocate and Rehabilitate roads whenever possible</p>	
	<p>Federal Energy Regulatory Commission License and Permits</p>	<p>1 Allow where compatible and mitigate when zone is adversely affected Coordinate with Northwest Power Planning Councils protected area designation</p>	
	<p>Property Line Location Property Boundary and Corner Maintenance</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 100</p>	
	<p>Landownership Planning, Land Adjustment Planning, and All Adjustment Activities</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-100 and 101</p>	
<p><u>FACILITIES</u></p>	<p>Road Construction</p>	<p>1. Road use will be designed by project planning, design criteria, and Forest Management Objectives 1 Locate FA&O structures outside the zone to the extent practical 2 Solid waste landfills will not be permitted in the zone 3 Transfer systems will be allowed if they are compatible with Forest standards</p>	<p>1 Locate roads outside the zone to the extent practical.</p>
	<p>Road Operation</p>		<p>2 When a prudent and feasible alternative exists, abandon or relocate existing roads</p>
	<p>FA&O Construction and Reconstruction</p>		<p>3 To the extent practical, create new or replacement habitat in the location, design and operation of road related rock pits, borrow areas and other disturbed sites 4 Restrict activities to time periods most suited to minimize unavoidable impacts 5 Maintain or enhance hydraulic flow consistent with habitat requirements 6 To the extent practical, cross habitat with structures rather than fill Use a 90 degree crossing where possible See FSH 7709 56b Drainage Structures Handbook, or revision</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p>FACILITIES (continued)</p>			<p>7 Provide for erosion control during and after construction (sediment traps, revegetation, etc) All roads within this zone shall have an erosion resistant surface. Vegetation is the preferred surface on closed roads</p> <p>8 No channelization, stream relocation or associated activity will be approved if a feasible alternative exists</p> <p>9 In projects where channelization is undertaken, the design will provide that the aquatic habitat is restored to original or better condition</p> <p>10 All new road construction will maintain or enhance fish passage Follow the guidelines in Engineering Technical report ETR 7700-5 "Fish Versus Culverts" or revision</p> <p>11 To the extent practical, correct existing barriers to fish passage; inventory road related passage obstructions and prioritize for corrective measures</p>
<p>PROTECTION</p>	<p>Fire Prevention</p> <p>Fire Suppression</p> <p>Fire Hazard Abatement</p> <p>Preattack Facilities Development</p> <p>Law Enforcement</p> <p>Forest Pest Management</p>	<p>1. Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan.</p> <p>1. Implement fire suppression strategies commensurate with the habitat management objectives</p> <p>2. All fire suppression tactics and resources may be appropriate Emphasize maintenance and enhancement of sub-drainage objectives</p> <p>1. Forest-wide Standards and Guidelines apply See p IV- 103</p> <p>1 Forest-wide Standards and Guidelines apply. See p IV- 103</p> <p>1 Forest-wide Standards and Guidelines apply. See p IV-103</p> <p>1 Suppress Forest pests when they adversely affect the vegetation component essential for maintaining the zone and/or when unacceptable damage to resources would occur if no controls are applied</p>	<p>1 Generally tractors will not be compatible</p> <p>1 Treatment of activity generated and natural fuels is appropriate when compatible with the subdrainage objectives.</p> <p>1 Develop preattack facilities when compatible with the habitat objectives</p> <p>1 Use suppression techniques which avoid or minimize degradation of water quality as determined by state Forest practices</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable damage and meet resource objectives</p> <p>3 Rodenticides should not be used in this allocation</p>

MANAGEMENT PRESCRIPTION: EW-3

TITLE: Key Big Game Habitat/Unroaded

GOAL STATEMENT: Manage deer, elk, and mountain goat winter range and key summer range to meet habitat requirements for sustaining optimum carrying capacity in an unroaded setting.

DESCRIPTION: Deer and elk winter ranges are generally at low elevations, on south and/or east facing slopes with reduced snow depth and early melt-off of snow. Because of these conditions, these areas are highly desirable for winter and early spring recreation activities, and dry out early to become high fire danger areas. These habitats have 10-60 percent of the area in openings (used by big game for foraging) containing shrubs, grasses, and forbs with scattered conifer trees, and 20-80 percent of the area in conifer stands (used by big game for cover). The quality of the forage and the amount of thermal cover combined with the amount of human disturbance are the factors that determine the carrying capacity of these areas for big game in winter. Mountain goat summer and winter ranges are generally adjacent to each other at high elevations, well within the Forest, and just above and below the line separating suitable and unsuitable timber harvesting stands. Summer range consists of dense stands of old conifer trees intermingled with small meadows that provide food and shelter. Winter range consists of open, steep, rocky ridges with grasses, forbs, and shrubs dominating a landscape containing scattered conifer trees. Human activity, reductions in winter habitat, and lack of quality forage in summer range limit the populations of mountain goats.

MANAGEMENT PRESCRIPTION: GF

TITLE: General Forest

GOAL STATEMENT: Provide for long-term growth and production of commercially valuable wood products at a high level of investment in silvicultural practices.

DESCRIPTION: Future stands will vary from intensive timber management typified by regular spacing, relatively even age and height, to those that are similar to natural stands. Regenerated stands will have a high ratio of genetically superior stock and may receive cultural treatments throughout the rotation. The cultural practices will be determined on a site specific basis depending on the biological and economic conditions of the stand. Regeneration harvest will generally occur at culmination of mean annual increment. Logging will be by the most economical methods compatible with silvicultural requirements, soil and water standards and landform. Road densities and standards would also be dependent upon these conditions. In the General Forest area, the relative intensity of management is set by the Forest Plan. However, site specific details and locations of treatments will be determined in the prescription written or field reviewed by a certified silviculturist.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RECREATION</u>	Recreation Planning and Inventory	1 Visual Quality Objective MAXIMUM MODIFICATION 2 Plan timber harvest and other vegetative treatments to meet ROS setting objectives for applicable class, roaded natural to urban	1 Cutting units may dominate natural patterns but must repeat natural form, line, color and texture. 2 Provide a variety of age classes 3 Cutting units should generally avoid obliteration of high use dispersed recreation sites and other specific locations of special interest to recreation visitors 4 A higher VQO may be considered along roads, trails and dispersed sites within this prescription
	Cultural Resource Inventory Evaluation, Assessment and Protection	1 Forest-wide Standards and Guidelines apply. See p IV- 66	
	Facility and Site Reconstruction and Construction	1 Forest-wide Standards and Guidelines apply See p IV-67 and 68	
	Facility and Site Management	1 Forest-wide Standards and Guidelines apply See p IV-68	
	Use Administration	1 Forest-wide Standards and Guidelines apply See p IV-68	
	Trail Reconstruction and Construction	1. Construct new trails or relocate existing trails outside of this prescription if recreation management and trail objectives can be met	
	Trail System Maintenance and Operation	1 Forest-wide Standards and Guidelines apply See p. IV- 69	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p> <p>Non-Structural Habitat Improvement</p> <p>Structural Habitat Improvement</p>	<p>1 Manage primary cavity excavators at 20 percent or higher of the potential population level</p> <p>1 To the extent practical schedule timber harvest to meet the needs for big game diversity, especially adjacent to winter range</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-83 and 84</p>	
<p><u>RANGE</u></p>	<p>Range Planning and Inventory</p> <p>Range Non-Structural Improvements</p> <p>Range Structural Improvements</p> <p>Range Structural Improvement Maintenance</p> <p>Range Administration and Management</p>	<p>1. Grazing of suitable range by livestock shall emphasize range management practices that favor timber production</p> <p>2 Management of the range resource under this prescription will feature a full range of management schemes</p> <p>3 Recognize potential of timber sales to create new forage producing areas</p> <p>4 Provide for logical development of sale areas that can be packaged with existing grazing allotments or for new transitory grazing areas.</p> <p>1 Use only compatible species in range forage improvement projects</p> <p>1 Utilize the National Forest Landscape Management Handbook (USDA No 484) "Range" in the design and application of improvements</p> <p>1. Forest-wide Standards and Guidelines apply. See p IV-89</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-89</p>	<p>1 The management scheme applied will be one which best meets the timber management goal for the specific area. Management seeks utilization of forage allocated to livestock</p> <p>1 Grass seeding will not be done when it interferes with tree regeneration or growth</p> <p>1. Cost effective management systems and techniques including fences and water developments are designed and applied to obtain relatively uniform livestock distribution and use of forage, and to maintain plant vigor.</p>
<p><u>TIMBER</u></p>	<p>Regeneration Harvest</p> <p>Intermediate Harvest</p>	<p>1. Harvest generally at culmination of mean annual increment Regeneration practices subject to standards in Regional Guide and NFMA Regulations</p> <p>1. Up to two commercial thinnings may be considered</p> <p>2 Remove dead and dying trees, as economical, from areas not scheduled for regeneration harvest</p>	<p>1 Clearcut</p> <p>2 Shelterwood cut</p> <p>3 Seed tree cut</p> <p>1 Thin to maintain a minimum basal area that will utilize site potential and produce an economical harvest</p> <p>1 Salvage Sales should be considered, where dead or dying trees exceed minimum wildlife needs</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>TIMBER</u> (continued)	Silvicultural Examination and Prescription	1. Make examination prior to any activity and as required for certification of reforestation and thinning.	1 Stand examination
	Reforestation	1. Use compatible reforestation methods	1 Plant all nonstocked areas following regeneration harvest unless adequate natural regeneration of desired species is expected within three years. 2 Perform site preparation as required by site specifications 3 Protect seedlings from animal damage where stocking level is threatened.
	Timber Stand Improvement	1 Use methods compatible with the goal	1 Release regeneration overtopped by competing vegetation 2 Fertilization will be used where it is cost effective, and on soils where increased growth of conifers can be expected based on past experience or research
	Timber Sale Preparation and Timber Harvest Administration	1 Forest-wide Standards and Guidelines apply See p. IV- 93 and 94	
	Nursery Management	1 Collect seed in sufficient quantities to meet program reforestation needs plus a sufficient reserve for natural disasters.	1 Cone collection 2 Seed certification.
	Genetic Tree Improvement	1. Implement the Forest Tree Improvement Program Include seed orchards and plantations to evaluate the genetic quality of selected trees	1 Select and maintain superior trees 2 Collect seed from superior trees
<u>WATER</u>	Planning	1. Forest-wide Standards and Guidelines apply See p IV-94	
	Improvement	1. Forest-wide Standards and Guidelines apply See p. IV-94 and 96	
	Administration and Management	1 Forest-wide Standards and Guidelines apply See p. IV- 94 and 95	
	Rights and Use Management	1 Forest-wide Standards and Guidelines apply. See p. IV-95 and 96	
<u>SOIL</u>	Planning and Inventory	1 Forest-wide Standards and Guidelines apply. See p IV-96	
	Improvement	1 Forest-wide Standards and Guidelines apply See p IV- 96	
	Administration and Management	1. Forest-wide Standards and Guidelines apply. See p IV-97	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>AIR</u>	<p>Planning</p> <p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-98</p> <p>1. Forest-wide Standards and Guidelines apply. See p IV-98</p>

<u>LANDS</u>	<p>Special Use Management</p> <p>Right-of-Way Grants for Roads and Trails</p> <p>Federal Energy Regulatory Commission License and Permits</p> <p>Property Line Location Property Boundary and Corner Maintenance</p> <p>Landownership Planning Land Adjustment Planning, and All Adjustment Activities</p> <p>Rights-of-Way Cost-Share Agreements</p>	<p>1. Transportation and utility corridors are permitted where suitable</p> <p>1 Grants will be made under then prevailing guidelines</p> <p>1. Recommend only compatible uses</p> <p>1 Property lines adjacent to timber production areas will be surveyed, marked and posted</p> <p>2 These property lines will have high priority in the use of available Land Line Location funds</p> <p>1 Use land exchange to facilitate resource management</p> <p>1 Maximize use of cost share process to reduce miles of road (acres out of production), costs, and assure that location and standard of roads within the National Forest portion of agreement areas are compatible with management goals.</p>	

MANAGEMENT PRESCRIPTION: MP-1

TITLE: Mather Memorial Parkway

GOAL STATEMENT: Manage area to maintain and enhance its outstanding scenic and recreation qualities.

DESCRIPTION: This is an area classified by executive order, encompassing a zone extending 1/2 mile either side of U.S. Highway 410, to be managed primarily for scenic and recreational purposes. Developments and management activities within the allocation generally are not visually evident. The natural existing or established landscape will generally have vegetation on forested lands that is composed of large old growth trees in the overstory or in groves intermixed with a variety of age classes in the understory. The general perception of the landscape is a natural appearing environment. Motorized use is permitted within these areas to the extent it is compatible with the management intent.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1 Visual Quality Objective. RETENTION</p> <p>2. Plan recreation activities in conformance with appropriate ROS class: Semi-primitive to Rural.</p>	<p>1. Dispersed sites may be modified to accommodate recreational facilities and uses</p> <p>2 Visual analysis is required to blend activities with the naturally established landscape.</p> <p>3 Structures within the area will be architecturally compatible with the naturally established landscape</p> <p>4 Rehabilitation measures are to be applied to the landscape where needed to improve visual setting</p> <p>5. Prescribed fire may be used to enhance visual quality and to maintain natural fire succession</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV- 66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1. Provide high quality recreation sites and facilities with development of activities and opportunities desired by the recreating public.</p>	
	<p>Facility and Site Management</p>	<p>1. Forest-wide Standards and Guidelines apply. See p. IV- 68</p>	
	<p>Use Administration</p>	<p>1. Forest-wide Standards and Guidelines apply. See p. IV- 68</p>	
	<p>Trail Reconstruction and Construction</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV- 68 and 69</p>	
	<p>Trail System Maintenance and Operation</p>	<p>1 Forest-wide Standards and Guidelines apply. See p. IV-69</p>	

MP-1

<u>MINERALS AND GEOLOGY</u>	<p>Locatable Minerals</p> <p>Leasable Energy Minerals</p> <p>Common Variety Minerals</p> <p>Recreational Mineral Activities</p>	<p>1 Continue the existing withdrawal along the highway (330 feet each side of the centerline), unless other existing laws and regulations will provide adequate protection</p> <p>2 Ensure that prior valid existing rights exist before approving any mining related activities within the withdrawn area.</p> <p>1. If leasable mineral related activities are incompatible with the management objectives for the withdrawn area, attach a no surface occupancy stipulation to the lease</p> <p>1. Allow mineral material sites when compatible with the goal</p> <p>1 Consider designating panning areas</p>	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		<p>1 Forest-wide Standards and Guidelines apply See p IV- 99 and 100</p>	
<u>LANDS</u>	<p>Special Use Management</p> <p>Right-of-Way Grants for Roads and Trails</p> <p>Federal Energy Regulatory Commission License and Permits</p> <p>Property Line Location Property Boundary and Corner Maintenance</p> <p>Landownership Planning, Land Adjustment Planning, and All Adjustment Activities</p> <p>Rights-of-Way Cost-Share Agreements</p>	<p>1 Permit transportation and utility corridors when compatible with the goal</p> <p>1 Provide appropriate access to inholders under then existing guidelines</p> <p>1 Recommend only compatible uses</p> <p>1. Survey, mark and post lines of all other ownerships within the area not planned for acquisition</p> <p>1 Use land exchange to facilitate resource management</p> <p>1. Forest-wide Standards and Guidelines apply See p IV- 101</p>	
<u>FACILITIES</u>	<p>Road Construction</p> <p>Road Operation</p> <p>FA&O Construction and Reconstruction</p>	<p>1 Provide and manage roads as needed to accomplish resource objectives</p> <p>1 Appropriate road use will be determined by project planning and design</p> <p>1 Forest-wide Standards and Guidelines apply. See p IV- 102 and 103</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>PROTECTION</u></p>	<p>Fire Prevention</p>	<p>1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan</p>	
	<p>Fire Suppression</p>	<p>1. Implement fire suppression strategies that emphasize the protection of recreation facilities and values or other special values of the area.</p> <p>2 Fire suppression tactics should emphasize the protection of life and property while minimizing the physical disturbance of the resources. The use of all fire suppression resources is appropriate</p>	
	<p>Fire Hazard Abatement</p>	<p>1 Treatment of both activity generated and natural fuels is appropriate when coordinated with the scenic, recreational, or other special management objectives of the area</p> <p>2 The protection of recreation values will be emphasized during the planning and implementation of these projects</p>	
	<p>Preattack Facilities Development</p>	<p>1 Develop only those preattack facilities that are compatible with the special scenic and recreational values of the areas</p>	
	<p>Law Enforcement</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV- 103</p>	
	<p>Forest Pest Management</p>	<p>1. Suppress insects and diseases when outbreaks threaten managed resources and/or users</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives</p>	

MANAGEMENT PRESCRIPTION: OG-1

TITLE: Old-Growth Management

GOAL: Manage for old growth habitat to achieve "ecosystem diversity, preservation of aesthetic qualities", and/or "wildlife and plant habitat".

DESCRIPTION: The Regional Guide for the Pacific Northwest Region directs all Forests to use a standard definition of old growth. Following are the descriptions of the characteristics needed to meet the requirements of this prescription.

1. **ECOSYSTEM DIVERSITY:** Ecosystem diversity is a representation of the variety that exists in biotic communities and is characterized by the number of species on a site and by the number of communities at all sites. The variety of management prescriptions will provide many and varied stand conditions and species, helping to maintain ecosystem diversity in managed, younger stands. However, enough of all types of old growth are required to maintain species dependent on old growth and preserve the various kinds of old growth communities found on the Forest.

2. **PRESERVATION OF AESTHETIC QUALITIES** People using the forest for recreation purposes enjoy old growth trees for their aesthetic and awe-inspiring qualities. Old trees represent a living link with the past and provide an important visual reference to the natural successional process of the forest environment.

Old growth stands are typically thought of as having an atmosphere that is peaceful, cathedral-like, and park-like or an atmosphere of being small, closed in, dominated and encompassed. The stand feels cool and refreshing, and smells musty from the decadent vegetation (rotting logs, snags, fruiting bodies of fungus and underbrush). The trees have deep furrowed bark, large diameters at the base of the tree (generally 21" in diameter or larger), tall and straight boles, (over 100 feet tall) rotten cracks, broken limbs, mosses, lichens, and rounded tops that create the illusion of being old.

3. **WILDLIFE AND PLANT HABITAT:** The indicator species for old growth and mature habitat is the spotted owl. Habitat for spotted owls includes mature and overmature trees dominant in the overstory, a multi-layered canopy, trees of several age classes, large amounts of standing dead trees and down material present, canopy crown closure of 45 percent or greater, and elevations between 1500 and 5000 feet.

The 2200 acres (more or less depending upon local circumstances) of suitable habitat may be contiguous, or scattered over a area of about 9000 acres. There is usually unsuitable habitat (either naturally occurring or from harvest) intermingled with the suitable habitat. It is common to find logging activities next to suitable spotted owl habitat. Road use and recreation activities will often be taking place within the habitat site.

Maintenance and reproduction of spotted owls is of high concern, therefore, limit activities that may affect reproduction.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RECREATION</u>	Recreation Planning and Inventory Cultural Resource Evaluation, Assessment and Protection	1 Visual Quality Objective Retention 2 Plan recreation activities and facilities that meet applicable ROS class criteria Semi-primitive non-motorized to Roaded natural 1 Forest-wide Standards and Guidelines apply See p IV- 66	1 Rehabilitation measures are to be applied to the landscape where needed to improve the visual setting

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u> (continued)</p>	<p>Facility and Site Reconstruction and Construction</p> <p>Facility and Site Management</p> <p>Use Administration</p> <p>Trail Reconstruction and Construction</p> <p>Trail System Maintenance and Operation</p>	<p>1 New facilities should be designed and managed such that they are consistent with the goals of the prescription</p> <p>1 Manage existing facilities so that they're consistent with the goals of the prescription</p> <p>1 Forest-wide Standards and Guidelines apply See p IV- 68</p> <p>1. Construct or reconstruct trails to conform with goals of old growth management and to enhance the recreation experience opportunities presented by old growth habitats</p> <p>2 As opportunities become available, build trails where appropriate, to provide viewing of old growth and old growth dependent species</p> <p>1 Manage recreation use to be compatible with the old growth setting Prohibit non-conforming activities and relocate uses outside this prescription</p>	
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p>	<p>1 For each spotted owl network site, maintain within 2 1 miles of the owl's center of activity (whichever is less) .</p> <ul style="list-style-type: none"> a. 2200 acres of high quality old growth and/or mature habitat, or b all suitable habitat <p>As suitable habitat becomes available, it will be added to these sites until there is 2200 acres at each site.</p> <p>2 Maintain the distribution of spotted owl habitat in a network that provides for all species dependent upon mature or old growth habitat (mature and old growth network) Distribution of sites in the network will meet the standards and guidelines established in the Supplemental Environmental Impact Statement on spotted owls</p> <p>3 Follow the Regional Monitoring Plan for spotted owls</p>

Forest-wide Standards and Guidelines apply See p IV-100</p> <p>1 National Forest ownership is most desirable</p> <p>1 Maximize use of the cost share program in control of road locations, numbers, standards, etc where these areas coincide with cost share areas</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>FACILITIES</u></p>	Road Construction	<p>1. No roads will be built if a reasonable alternative exists</p>	
	Road Operation	<p>1 Appropriate road use will be determined by project planning and design</p>	
	FA&O Construction and Reconstruction	<p>1 To the extent practical, locate structures outside this prescription</p>	
<p><u>PROTECTION</u></p>	Fire Prevention	<p>1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan</p>	
	Fire Suppression	<p>1 Implement fire suppression strategies commensurate with the habitat management objectives</p> <p>2 All fire suppression tactics and resources may be appropriate</p>	
	Fire Hazard Abatement	<p>1 Treatment of both activity generated and natural fuels is appropriate when coordinated with the habitat management objectives of the specific area</p>	
	Preattack Facilities Development	<p>1 Develop preattack facilities in coordination with the habitat management objectives of each specific area</p>	
	Law Enforcement	<p>1 Forest-wide Standards and Guidelines apply See p IV- 103</p>	
	Forest Pest Management	<p>1. Suppress insect and disease outbreaks to ensure protection of old-growth trees and other resources. Insects and disease are important components of old growth</p>	
		<p>2 Survey insects and diseases common to old growth that may threaten immediate and adjacent areas</p>	

MANAGEMENT PRESCRIPTION: OG-2

TITLE: Mature Habitat

GOAL STATEMENT: Manage for mature to old growth habitat for wildlife and plant species dependent upon this habitat.

DESCRIPTION: The indicator species for this prescription are the marten/northern three-toed woodpecker and pileated woodpecker. These indicators plus the spotted owl are designed to provide a mature and old growth network. The network is to provide habitat for all species dependent upon mature or old growth habitat. The habitat for the marten/northern three-toed woodpecker and pileated woodpecker is described as mature or overmature trees in the overstory, a three-layered canopy of trees in several age classes, large amounts of dead standing and down trees present, and a canopy closure of 95 percent or greater. Habitat for marten/northern three-toed woodpeckers is at elevations of about 2000 to 7000 feet, and for the pileated woodpecker, about 1500 to 5000 feet in elevation.

The marten/northern three-toed woodpecker habitat is a 160 acre contiguous habitat. One site will be found every 4000 to 5000 acres and it will be overlapped with spotted owl and pileated woodpecker sites when possible. An additional 160 acres of habitat is needed for developing future marten/northern three-toed woodpecker habitat. This additional acreage may be in any successional stages. The location of the 160 acres of mature habitat will change through time in the 320 acre site.

The pileated woodpecker habitat is 300 acres, made of stands of no less than 50 acres within a 1000 acre area. One site will be found every 12,000 acres and these sites should be overlapped with spotted owls when possible. An additional 300 acres of habitat is needed for pileated woodpecker sites that may be in any successional stage but must have a high number of snags to provide food. The location of the 300 acres of mature habitat will change through time in the 600 acre site.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RECREATION</u>	Recreation Planning and Inventory	1. Visual Quality Objective Partial Retention 2 Recreation Opportunity Spectrum Class Criteria Semi-primitive non-motorized to roaded natural.	
	Cultural Resource Evaluation, Assessment and Protection	1 Forest-wide Standards and Guidelines apply See p IV- 66	
	Facility and Site Reconstruction and Construction	1. New and reconstructed facilities should be consistent with the goals of the prescription	
	Facility and Site Management	1. Forest-wide Standards and Guidelines apply See p IV- 68	
	Use Administration	1 Forest-wide Standards and Guidelines apply See p IV- 68	
	Trail Reconstruction and Construction	1 As opportunities become available, build trails to provide viewing of indicator species and mature habitat	
	Trail System Maintenance and Operation	1 Forest-wide Standards and Guidelines apply See p IV- 69	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p>	<p>1 Maintain 160 acres of contiguous suitable mature or old growth habitat for marten and 300 acres of mature or old growth habitat for pileated woodpeckers at all times</p> <p>2 Maintain the distribution of habitat in a network that provides for all species dependent upon mature or old growth habitat (mature and old growth network) Follow Region 6 Management Requirement Guidelines for wildlife</p> <p>3 Pileated woodpecker areas will have a minimum of 60 percent potential population of primary cavity excavator habitat on the entire area The mature habitat component (160 acres for pine marten and 300 acres for pileated woodpecker) will strive to maintain 100 percent potential population of primary cavity excavators.</p> <p>4 Exact boundaries will be undetermined until site specific project analysis is completed Factors to consider in determining exact locations will be.</p> <p>a. Overlap with resource allocations that do not harvest timber b Provide mature or old growth habitat c Maintain habitat for the "mature and old growth network " d. Provide better management boundaries e Maintain suitable habitat after catastrophic events</p> <p>5 Part of the habitat in these stands will have decay, insects, and disease apparent</p>	
	<p>Non-Structural Habitat Improvement</p>	<p>1 Habitat improvements will be done to</p> <p>a Meet the management requirements for indicator species b Improve factors that may be limiting indicator species and dependent species from occupying network sites</p>	
	<p>Structural Habitat Improvement</p>	<p>1 Habitat improvements will be done to</p> <p>a Meet the management requirements for indicator species b Improve factors that may be limiting indicator species and dependent species from occupying network sites</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RANGE</u>	<p>Range Planning and Inventory</p> <p>Range Non-Structural and Structural Improvements</p> <p>Range Structural Improvement Maintenance</p> <p>Range Administration and Management</p>	<p>1 When areas occur within allotments, management will be at the same intensity as adjacent lands and compatible with the goal</p> <p>1 Forest-wide Standards and Guidelines apply See p IV- 89 and 92</p> <p>1 Forest-wide Standards and Guidelines apply See p IV- 89</p> <p>1 Forest-wide Standards and Guidelines apply. See p. IV- 89</p>	
<u>TIMBER</u>	<p>Regeneration Harvest</p> <p>Silvicultural Examination and Prescriptions</p> <p>Reforestation</p>	<p>1 Harvest will be to perpetuate the mature habitat characteristics and reduce the risk of loss of sites from natural events Habitat conditions will be achieved at about 120 years and be maintained until the stand is about 180 years old Final harvest is planned at about 180 years of age</p> <p>1. Leave primarily thrifty dominant trees when possible to maintain <i>timber production</i>, but <i>some</i> mistletoe infected and/or defective trees should be maintained to provide wildlife habitat</p> <p>2. Thin to maintain growth so that site productivity is utilized and to produce an economical harvest</p> <p>1. Use an appropriate mix of naturally occurring trees Regeneration will be by planting and natural seeding following harvest</p> <p>2 Perform site preparation as required by site specifications</p> <p>3 Protect plantations against animal damage</p> <p>4 Use reforestation methods, nursery stock, and stocking levels that help achieve the goals of the prescription</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>TIMBER</u> (continued)	Timber Stand Improvement Timber Sale Preparation, and Timber Harvest Administration Nursery Management and Genetic Tree Improvement	1 Manage stands to achieve large trees quickly. 1 Schedule activities to minimize harassment of wildlife 2 Make examination prior to any activity and as required for certification of reforestation and thinning 1 Use genetically superior tree stock when needed to achieve the goals of the prescription.	
<u>WATER</u>	Planning Improvement Administration and Management Rights and Use Management	1. Forest-wide Standards and Guidelines apply See p IV- 94 1. Forest-wide Standards and Guidelines apply See p IV-94 and 96 1 The riparian zones in this management prescription will be managed to provide mature habitat as well as meet the goals for the Riparian-Aquatic Habitat Protection Zone 1. Forest-wide Standards and Guidelines apply See p IV- 95 and 96	
<u>SOIL</u>	Planning and Inventory Improvement Administration and Management	1 Forest-wide Standards and Guidelines apply. See p IV-96 1. Forest-wide Standards and Guidelines apply See p IV- 96 1. Forest-wide Standards and Guidelines apply. See p IV- 97	
<u>AIR</u>	Planning Administration and Management	1 Forest-wide Standards and Guidelines apply See p IV-98 1. Forest-wide Standards and Guidelines apply See p IV- 98	
<u>MINERALS AND GEOLOGY</u>	Locatable Minerals	1 If the proposed activity will adversely impact nesting birds or other dependent species and it is reasonable, recommend mineral activities during pre-production stages not be conducted during the critical use period. Ensure all habitat-disturbing activities are essential for conducting the proposed mineral related activity	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>MINERALS AND GEOLOGY</u> (continued)</p>	<p>Leasable Minerals</p> <p>Common Variety Minerals</p> <p>Recreational Mineral Activities</p>	<p>1 Recommend that a stipulation be attached to leases which provides for the same reasonable restrictions as required for Locatable Minerals above</p> <p>1 Do not allow disposal of common variety minerals if removal will significantly and irreversibly impact old growth dependent species habitat, and alternative sources of these minerals are available</p> <p>1 Forest-wide Standards and Guidelines apply See p IV- 99</p>	
<p><u>RURAL COMMUNITY AND HUMAN RESOURCES</u></p>	<p>Not applicable to this prescription</p>

Recommend only compatible uses</p> <p>1. Forest-wide Standards and Guidelines apply See p IV- 100</p> <p>1 National Forest ownership is most desirable</p> <p>1 Maximize use of the cost share program in control of road locations, numbers, standards, etc. where these areas coincide with cost share areas.</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>FACILITIES</u></p>	Road Construction	<p>1 Provide and manage roads as needed to accomplish resource objectives</p>	
	Road Operation	<p>1 Appropriate road use will be determined by project planning and design</p>	
	FA&O Construction and Reconstruction	<p>1 Forest-wide Standards and Guidelines apply See p IV-102 and 103</p>	
<p><u>PROTECTION</u></p>	Fire Prevention	<p>1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan</p>	
	Fire Suppression	<p>1 Implement fire suppression strategies commensurate with the habitat management objectives</p> <p>2 All fire suppression tactics and resources may be appropriate</p>	
	Fire Hazard Abatement	<p>1 Treatment of both activity generated and natural fuels is appropriate when coordinated with the habitat management objectives of the specific area</p>	
	Preattack Facilities Development	<p>1 Develop preattack facilities in coordination with the habitat management objectives of each specific area</p>	
	Law Enforcement	<p>1 Forest-wide Standards and Guidelines apply See p IV-103</p>	
	Forest Pest Management	<p>1 Suppress insect and disease outbreaks to insure protection of old-growth timber and other resources</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damages and meet resource objectives</p> <p>3 Survey insects and diseases common to old-growth that may threaten immediate and adjacent areas</p>	

MANAGEMENT PRESCRIPTION: RE-1

TITLE: Developed Recreation

GOAL STATEMENT: Provide developed recreation in an Urban to Semi-Primitive Recreation Opportunity Spectrum (ROS) setting.

DESCRIPTION: This prescription is applicable to existing and potential developed recreation sites within the full spectrum of ROS settings. The areas allocated to this use include only the specific site on which development takes place. This prescription is also applicable to existing and potential Alpine (downhill) ski areas including runs, tows or lift facilities, shelters, lodges, services and parking lots. Associated developments such as skating rinks, toboggan runs, etc., may also be present. Potential sites allocated to this prescription will be managed to protect or enhance the future values and conditions desired.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p>RECREATION</p>	<p>Recreation Planning and Inventory</p>	<p>1 Visual Quality Objective Retention</p> <p>2 Plan recreation activities and facilities to provide a diverse range of recreation opportunities in ROS classes, semi-primitive to urban</p> <p>3 Develop partnerships and encourage recreation development through permits, joint ventures, and cooperative agreements</p> <p>4 Encourage development of recreation opportunities by the private providers</p> <p>5 Employ marketing strategies to determine wants and needs of recreation visitors Incorporate these wishes in recreation planning and development</p>	<p>1 A visual analysis is required to blend activities with the naturally established landscape</p> <p>2 Vegetative management plans are required prior to manipulation of vegetation</p> <p>3 Consistent with safety, retain the vegetative character of the area</p> <p>4 Manmade structures are to be architecturally compatible with the established landscape</p> <p>5 Sites may be modified to accommodate recreational facilities and uses</p> <p>6 Buildings should present naturally harmonious colors</p> <p>7 Trails will be located to take advantage of viewing opportunities</p> <p>8 Rehabilitation measures are to be applied to landscape where needed to improve the visual setting</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1 Provide high quality recreation sites and facilities with development of activities and opportunities desired by the recreating public</p> <p>2 Reconstruct all moderate to heavily used sites with high quality facilities</p> <p>3 Construct new recreation sites where demand is high and overuse problems are occurring at existing sites</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u> (continued)</p>	<p>Facility and Site Management</p> <p>Use Administration</p> <p>Trail Reconstruction and Construction</p> <p>Trail System Maintenance and Operation</p>	<p>1 Manage all recreation sites to provide high quality facilities and recreation opportunities</p> <p>2 Charge user fees in all facilities that can meet fee site requirements</p> <p>3 Provide interpretive facilities and programs in high use developed sites and where opportunities for public education are optimal</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-68</p> <p>1. Forest-wide Standards and Guidelines apply See p IV- 68 and 69</p> <p>1 Forest-wide Standards and Guidelines apply See p IV- 69</p>

MANAGEMENT PRESCRIPTION: RE-2

TITLE: Dispersed Recreation, Unroaded, Motorized

GOAL STATEMENT: Provide dispersed, unroaded recreation in a semi-primitive motorized recreation opportunity setting.

DESCRIPTION: This prescription is for application to unroaded areas in which trails are evident and maintained for the following types of uses.

RE-2a - Areas having existing or potential trails for motorbikes, hikers and horseback riders.

RE-2b - Areas having existing or potential 4x4 routes in addition to trails for motorbikes, hikers and horseback riders.

They are generally located in a natural appearing landscape setting. Winter motorized use is permitted where appropriate.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1 Visual Quality Objective RETENTION</p> <p>2 Plan recreation activities to conform to the ROS class criteria Semi-primitive motorized</p>	<p>1 A visual analysis is required to blend activities with the naturally established landscape</p> <p>2 Trails and routes will be located to take advantage of viewing opportunities and provide a variety of vegetative compositions, landscape character and viewing sequences</p> <p>3 Rehabilitation measures are to be applied to the landscape where needed to improve the visual setting</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 67 and 68</p>	
	<p>Facility and Site Management</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV- 68</p>	
	<p>Use Administration</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 68</p>	
	<p>Trail Reconstruction and Construction</p>	<p>1 Trails will be located or relocated to minimize substantial impacts to resource values also dependent upon semi-primitive conditions or settings</p>	
	<p>Trail System Maintenance and Operation</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 69</p>

Develop only those preattack facilities that are compatible with the unroaded nature and management objectives of the area</p> <p>1 Forest-wide Standards and Guidelines apply See p IV- 103</p> <p>1 Suppress insects and diseases when outbreaks threaten managed resources and/or users</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives</p>	

MANAGEMENT PRESCRIPTION: RE-3

TITLE: Dispersed Recreation, Unroaded, Non-Motorized

GOAL STATEMENT. Provide dispersed recreation in an unroaded, semi-primitive, non-motorized or primitive setting.

DESCRIPTION: This prescription is for application to unroaded areas in which trails are evident and maintained for non-motorized users. Landscape changes are generally not evident to those walking through the area. The area is essentially a natural or natural appearing environment. There is little evidence on-site of other users.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1 Visual Quality Objective RETENTION</p> <p>2 Plan recreation opportunities and activities to conform to ROS classes, primitive and semi-primitive non-motorized</p>	<p>1 A visual analysis is required to blend activities with the naturally established landscape</p> <p>2 Trails will be located to take advantage of opportunities to view scenery or special features present in the landscape</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 67 and 68</p>	
	<p>Facility and Site Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 68</p>	
	<p>Use Administration</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV- 68</p>	
	<p>Trail Reconstruction and Construction</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV-68 and 69</p>	
	<p>Trail System Maintenance and Operation</p>	<p>1. Forest-wide Standards and Guidelines apply. See p IV- 69</p>	
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p>	<p>1. Forest-wide Standards and Guidelines apply See p. IV- 80 through 83</p> <p>2 Manage primary cavity excavators near 100 percent of the potential population level.</p>	
	<p>Non-Structural Habitat Improvement</p>	<p>1. Habitat improvements will be done for management of wildlife species when not conflicting with the goals of the prescription</p>	
	<p>Structural Habitat Improvement</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 83 and 84</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RANGE</u></p>	<p>Range Planning and Inventory</p>	<p>1 Grazing of suitable range by livestock shall emphasize range management practices that favor dispersed recreation in an unroaded, semi-primitive, non-motorized or primitive setting</p> <p>2. Management of the range resource under this prescription will feature Level C scheme of management. There will be no increased range use</p>	<p>1 Level C Management - Management seeks full utilization of forage allocated to livestock</p> <p>1 Cost effective management systems and techniques including fences and water developments are designed and applied to obtain relatively uniform livestock distribution and use of forage, and to maintain plant vigor</p>
	<p>Range Non-Structural Improvements</p>	<p>1 Use only compatible species in range forage improvement projects</p> <p>2 Type conversion projects are not compatible</p>	
	<p>Range Structural Improvements</p>	<p>1 Utilize the National Forest Landscape Management Handbook (USDA No 484) "Range" in the design and application of improvements.</p>	
	<p>Range Structural Improvement Maintenance</p>	<p>1 Reconstruct, relocate, or eliminate range improvements that are not visually compatible</p>	
	<p>Range Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 89</p>	
<p><u>TIMBER</u></p>	<p>Sale Preparation</p>	<p>1 No harvest anticipated</p>	
	<p>Timber Stand Improvement</p>	<p>1 No precommercial thinning</p>	
<p><u>WATER</u></p>	<p>Planning</p>	<p>1 Existing and/or proposed trail construction, maintenance and use shall be designed to protect water resources.</p>	
	<p>Improvement</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 94 and 96</p>	
	<p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 94 and 95</p>	
	<p>Rights and Use Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 95 and 96</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>SOIL</u>	Planning and Inventory Improvement Administration and Management	1. Existing and/or proposed trail construction, maintenance and use shall be designed to protect soil resources. 2 Use soil information when locating and designing trails 1 Forest-wide Standards and Guidelines apply See p IV- 96 1 Forest-wide Standards and Guidelines apply See p IV- 97	
<u>AIR</u>	Planning Administration and Management	1 Forest-wide Standards and Guidelines apply. See p. IV- 98 1 Forest-wide Standards and Guidelines apply See p IV- 98	
<u>MINERALS AND GEOLOGY</u>	Locatable Minerals Leasable Energy Minerals Common Variety Minerals Recreational Mineral Activities	1 If roading and the use of motorized equipment is reasonably necessary for and incidental to mineral prospecting, exploration and development activities, approve the activity using Forest-wide Standards and Guidelines 2 If reasonable, limit access for pre-production prospecting and exploration activities to those methods that are most compatible with the objectives established for these areas (i.e., if helicopter access or packing are economically and technically reasonable, recommend they be used). 1 Recommend that a stipulation be attached to the lease which provides for the same restrictions as required for Locatable Minerals above 1 Forest-wide Standards and Guidelines apply See p IV- 98 and 99 1 Access, the use of motorized equipment, and the effects associated with conducting these activities will be limited to those that are in keeping the goals established for the area	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		1. Forest-wide Standards and Guidelines apply. See p IV- 99 and 100	
<u>LANDS</u>	Special Use Management Right-of-Way Grants for Roads and Trails Federal Energy Regulatory Commission License and Permits Withdrawals, Modifications, and Revocations Property Line Location Property Boundary and Corner Maintenance Landownership Planning, Land Adjustment Planning, and All Adjustment Activities Rights-of-Way Cost-Share Agreements	1. Avoid locating transportation and utility corridors in these areas 1 Provide appropriate access to inholders under then existing guidelines 1. Recommend only compatible use 1 Withdrawals from mineral entry are not appropriate in these areas 1. Survey, mark and post all National Forest property lines within these areas where private lands are not scheduled for acquisition 1 Retain National Forest lands Consolidate on a high priority basis 1 Limit participation to cooperating in determining the most appropriate means, location and standard for cooperator access to their lands Do not share cost	
<u>FACILITIES</u>	Road Construction Road Operation FA&O Construction and Reconstruction	1 No roads will be constructed or maintained except that a Reasonable access will be granted to inholders under then prevailing guidelines 1 Prohibit or eliminate road use 1 Forest-wide Standards and Guidelines apply See p IV- 102 and 103	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>PROTECTION</u>	Fire Prevention	1 Implement a moderate intensity fire prevention program as outlined in the Forest's Fire Management Action Plan	
	Fire Suppression	<p>1. Implement fire suppression strategies that emphasize the protection of recreation facilities and values or other special values of each management area</p> <p>2. Fire suppression tactics should emphasize the protection of life and property while minimizing the physical disturbance of the resources. The use of all fire suppression resources is appropriate</p>	
	Fire Hazard Abatement	<p>1. Treatment of both activity generated and natural fuels is appropriate when coordinated with the scenic, recreation, or other special management objectives of the area.</p> <p>2 The protection of recreation values will be emphasized during the planning and implementation of these projects</p>	
	Preattack Facilities Development	1. Develop only those preattack facilities that are compatible with the special visual and recreational values of the areas	
	Law Enforcement	1 Forest-wide Standards and Guidelines apply See p IV- 103	
	Forest Pest Management	<p>1 Suppress insects and diseases when outbreaks threaten managed resources and/or users where possible</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives.</p>	

MANAGEMENT PRESCRIPTION: RE-4

TITLE: Dispersed Recreation/Unroaded/Timber Harvest

GOAL STATEMENT: Provide for dispersed recreation, as well as long-term growth and production of commercially valuable wood products at a very low level of investment in timber cultural practices while maintaining the unroaded characteristics.

DESCRIPTION: Approximately 90 percent of future stands would come from natural regeneration. The remaining 10 percent would be regenerated by planting, after failure of natural regeneration to establish the stand. No stand improvements are planned between regeneration and harvest, future stands will closely resemble unmanaged conditions and will be typified by a tendency towards small irregularly spaced groups. Stands will generally have poor crown ratios and a wide range of age and height. Mortality due to tree competition, disease, and insects can be expected. Logging will generally be by aerial system to protect the unroaded characteristics of the area. Roads will not be constructed, except to protect adjacent resources.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
RECREATION	<i>Recreation Planning and Inventory</i>	<p>1. <i>Visual Quality Objective, Modification</i></p> <p>2 Plan recreation and timber harvest activities to meet appropriate ROS class Semi-primitive motorized</p>	<p>1. <i>A visual analysis is required to blend activities with the naturally established landscape</i></p> <p>2 Trails and routes will be located to take advantage of viewing opportunities and provide a variety of vegetative compositions, landscape character and viewing sequences</p> <p>3 Rehabilitation measures are to be applied to the landscape where needed to improve the visual setting</p> <p>4 Meet retention or partial retention from trails and viewpoints within the allocation, as appropriate</p>
	<i>Cultural Resource Evaluation, Assessment and Protection</i>	1 Forest-wide Standards and Guidelines apply See p IV-66	
	<i>Facility and Site Reconstruction and Construction</i>	1. Forest-wide Standards and Guidelines apply See p. IV-67 and 68	
	<i>Facility and Site Management</i>	1 Forest-wide Standards and Guidelines apply See p IV- 68	
	<i>Use Administration</i>	1 Forest-wide Standards and Guidelines apply See p IV-68	
	<i>Trail Reconstruction and Construction</i>	1 Forest-wide Standards and Guidelines apply. See p IV-68 and 69	
	<i>Trail System Maintenance and Operation</i>	1 Forest-wide Standards and Guidelines apply See p IV-69	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE

Treatment of both activity generated and natural fuels is appropriate when coordinated with the recreation management objectives of the area 2. The protection of recreation values will be emphasized 1 Develop only those preattack facilities that are compatible with the unroaded nature and management objectives of the area 1 Forest-wide Standards and Guidelines apply See p IV-103 1 Suppress insects and diseases when outbreaks threaten managed resources and/or users 2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives	

MANAGEMENT PRESCRIPTION: RM-1

TITLE: Intensive Range Management

GOAL STATEMENT: Provide for maximum forage production and utilization by commercial livestock with a high level of investment in range cultural practices

DESCRIPTION: Management seeks to optimize production and utilization of forage allocated for livestock use consistent with maintaining the environment and providing for multiple use of the range. Cultural practices such as brush control or seeding may be combined with fencing and water developments to implement complex grazing systems.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1 Visual Quality Objective Modification</p> <p>2 Plan recreation activities to conform to the appropriate ROS class criteria Roaded natural to Rural</p> <p>3 Plan and design recreation facilities in coordination with the development of range facilities and livestock management</p>	<p>1 A visual analysis is required to blend activities with the naturally established landscape</p> <p>2 Revegetate all disturbed areas to the extent compatible with the applicable visual quality objective</p> <p>3 Rehabilitation measures are to be applied to landscape where needed to meet the Visual Quality Objective where compatible with the range goal</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-67 and 68</p>	
	<p>Facility and Site Management</p>	<p>1 Forest-wide and Standards and Guidelines apply See p IV-68</p>	
	<p>Use Administration</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV-68</p>	
	<p>Trail Reconstruction and Construction</p>	<p>1 Construct or reconstruct trails to a standard which allows for trailing of livestock when desirable and identified in the Allotment Management Plan</p>	
	<p>Trail System Maintenance and Operation</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-69</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p>	<p>1 Manage primary cavity excavators at 20 percent of potential population level</p>	
	<p>Non-Structural Habitat Improvement</p>	<p>1 Maintain minimum forage and cover needs for big game diversity, especially adjacent to winter range</p> <p>2. Maintain existing hardwood components at a level compatible with the goal of this prescription</p>	
	<p>Structural Habitat Improvement</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-83 and 84</p>	
<p><u>RANGE</u></p>	<p>Range Planning and Inventory</p>	<p>1 Grazing of suitable range by livestock shall emphasize range management practices that favor livestock forage production</p> <p>2 Management of the range resource under this prescription will feature an intensive (Level D) management scheme</p> <p>3. Design range management system that will provide for reforestation needs</p>	<p>1. Level D Management - Management seeks to optimize production and utilization of forage allocated for livestock use consistent with maintaining the environment and providing for multiple use of the range</p> <p>2 Recognize potential of timber sales to create new forage producing areas</p> <p>3. Design silvicultural prescriptions to meet range objectives</p> <p>4 Utilize prescribed fire where appropriate to enhance forage production, palatability, and access</p>
	<p>Range Non-Structural Improvements</p>	<p>1 Use forage species and practices which will maximize or favor forage production for livestock</p>	<p>1. Where necessary, seed clearcuts to desirable forage to produce an average of 1000 pounds of forage (air dry) at the end of the first decade Forage levels will be noncompetitive with tree stocking</p> <p>2 Cultural practices such as brush control or seeding may be combined with fencing and water developments to implement complex grazing systems. Type conversions will not be practiced</p>
	<p>Range Structural Improvements</p>	<p>1 Utilize the National Forest Landscape Management Handbook (USDA No. 484) "Range" in the design and application of improvements</p>	<p>1 Cost effective management systems and techniques including fences and water developments are designed and applied to obtain relatively uniform livestock distribution and use of forage and to maintain plant vigor.</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE

MANAGEMENT | DESCRIPTION: RN-1

TITLE: Research Natural Areas

GOAL STATEMENT: Provide for; (1) Preservation of examples of all significant natural Ecosystems for comparison with those influenced by man, (2) educational research areas for ecological and environmental studies, and (3) preservation of gene pools for typical and rare and endangered plants and animals.

DESCRIPTION. Research Natural Areas (RNA) contain either examples of typical natural ecosystems or unique kinds of vegetation, animals, and land which are reserved for scientific and educational use. This use is restricted to non-manipulative and non-destructive research. On the Wenatchee National Forest there are two established RNAs: **Meeks Table** and **Thompson Clover**. Two additional areas have been studied and are candidates for addition to the system. They are: **Fish Lake**, a marsh-bog community, and **Eldorado Creek**, a montane serpentine community. Several new areas on the Forest are candidates as Research Natural areas to meet regional cell (ecosystem) needs. A Research Natural Area establishment report will be prepared for each recommended area when the Forest Plan is implemented. These reports will describe the boundaries of the areas. Until the reports are signed by the Chief of the Forest Service, the areas designated in this Plan are recommendations. They will be managed to maintain their suitability as RNAs.

<u>SOIL</u>	<p>Planning and Inventory</p> <p>Improvement</p> <p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-96</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-96</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-97</p>	
<u>AIR</u>	<p>Planning</p> <p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-98</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-98</p>	
<u>MINERALS AND GEOLOGY</u>	<p>Locatable Minerals</p>	<p>1 Propose that the area be withdrawn from entry under the 1872 Mining Law using the Forest-wide Standards and Guidelines for withdrawals</p> <p>2 After the area is withdrawn, determine if valid prior-existing rights to explore for or mine locatable minerals exist before approving such activities under Forest-wide Standards and Guidelines</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>FACILITIES</u></p>	<p>Road Construction</p>	<p>1. No roads will be constructed or maintained except that a reasonable access will be granted to landlocked inholders under the then prevailing guidelines</p>	
	<p>Road Operations</p>	<p>1 Prohibit or eliminate road use</p>	
<p><u>PROTECTION</u></p>	<p>Fire Prevention</p>	<p>1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan</p>	
	<p>Fire Suppression</p>	<p>1. Management of natural fires will be addressed in the Establishment Report for each specific Research Natural Area. All wildfires will be suppressed utilizing an appropriate suppression strategy. Suppression tactics which minimize physical disturbance will be used</p> <p>2 All human caused fires will be considered wildfires</p>	
	<p>Fire Hazard Abatement</p>	<p>1 Naturally occurring fires burning within prescription will be managed in an attempt to replicate the natural fire cycle if it is appropriate to the management objectives of the Research Natural Area</p> <p>2 Prescribed burning may be used to maintain ecologic conditions (Ref FSM 4063.41-4)</p>	
	<p>Preattack Facilities Development</p>	<p>1. The development of preattack facilities is not appropriate except on the exterior boundaries of the area where such facilities would supplement the protection of the adjacent lands</p>	
	<p>Law Enforcement</p>	<p>1 Use special closures when necessary to protect the RNA from actual or potential damage from public use when appropriate</p>	
	<p>Forest Pest Management</p>	<p>1 Suppress insect and disease outbreaks to meet RNA objectives</p> <p>2 Use these areas to observe insects and diseases in undisturbed areas</p> <p>3 Survey pest populations as a management strategy for adjacent resource areas</p>	

MANAGEMENT PRESCRIPTION: SI-1

TITLE: Classified Special Areas - Scenic and/or Recreation

GOAL STATEMENT: Manage Special Areas for recreation use, substantially in their natural conditions.

DESCRIPTION: These areas are classified under 36 CFR 294.1 and managed for recreation use substantially in their natural condition. The purpose of classifying these areas is to protect the natural beauty and, where appropriate, foster public use and enjoyment of the feature or environment (scenic areas possess outstanding or unique natural beauty). They occupy large areas of land where some multiple use activities may be compatible. Motorized use is permitted within these areas to the extent it is compatible with the management intent. Developments such as resorts, parking areas, campgrounds, etc., are located outside of the Special Area whenever possible

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1 Visual Quality Objective RETENTION</p> <p>2. Plan recreation activities in conformance with appropriate ROS class Primitive to Roaded natural</p>	<p>1 Dispersed sites may be modified to accommodate recreational facilities and uses.</p> <p>2 Visual analysis is required to blend activities with the naturally established landscape.</p> <p>3 Structures within the area will be architecturally compatible with the naturally established landscape.</p> <p>4. Rehabilitation measures are to be applied to the landscape where needed to improve visual setting</p> <p>5 Prescribed fire may be used to enhance visual quality and to maintain natural fire succession</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV-66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1. Construct new facilities outside this prescription when viable alternatives exist</p>	
	<p>Facility and Site Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-68</p>	
	<p>Use Administration</p>	<p>1 Forest-wide Standards and Guidelines apply. See p. IV-68</p>	
	<p>Trail Reconstruction and Construction</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-68 and 69</p>	
	<p>Trail System Maintenance and Operation</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV-69</p>

IV-92 and 93</p> <p>1. No precommercial thinnings</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>TIMBER</u> (continued)	Timber Sale Preparation and Timber Harvest Administration Nursery Management and Genetic Tree Improvement	1 Forest-wide Standards and Guidelines apply. See p IV-93 and 94 1 No special practice	
<u>WATER</u>	Planning Improvement Administration and Management Rights and Use Management	1 Forest-wide Standards and Guidelines apply. See p IV-94 1 Forest-wide Standards and Guidelines apply See p. IV-94 and 96 1. Forest-wide Standards and Guidelines apply See p. IV-94 and 95 1 Forest-wide Standards and Guidelines apply See p IV-95 and 96	
<u>SOIL</u>	Planning and Inventory Improvement Administration and Management	1 Forest-wide Standards and Guidelines apply See p IV-96 1. Forest-wide Standards and Guidelines apply See p IV-96 1 Forest-wide Standards and Guidelines apply See p IV-97	
<u>AIR</u>	Planning Administration and Management	1. Forest-wide Standards and Guidelines apply See p IV-98 1. Forest-wide Standards and Guidelines apply See p IV-98	
<u>MINERALS AND GEOLOGY</u>	Locatable Minerals	1 Determine where existing laws and regulations will not adequately protect areas classified Scenic Special Interest Areas, and propose that those areas be withdrawn from entry under the 1872 mining law 2 After an area has been withdrawn, ensure that prior valid existing rights exist before approving any mining related activities within the area	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>MINERALS AND GEOLOGY</u> (continued)	Leasable Energy Minerals Common Variety Minerals Recreational Mineral Activities	1 If leasable mineral related activities are incompatible with the management objectives for the area, and it is reasonable to do so, attach a no surface occupancy stipulation to the lease 2 If no surface occupancy is unreasonable, then propose the area be withdrawn 1 Where feasible, locate all mineral material sites out of these areas 1 Forest-wide Standards and Guidelines apply See p. IV-99	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		1 Forest-wide Standards and Guidelines apply See p. IV-99 and 100	
<u>LANDS</u>	Special Use Management Right-of-Way Grants for Roads and Trails Federal Energy Regulatory Commission License and Permits Property Line Location Property Boundary and Corner Maintenance Landownership Planning, Land Adjustment Planning, and All Adjustment Activities Rights-of-Way Cost-Share Agreements	1. Avoid locating transportation and utility corridors in these areas 1 Provide appropriate access to inholders under then existing guidelines 1 Recommend against these uses 1 Survey, mark and post lines of all other ownerships within the area not planned for acquisition 1 Retain existing National Forest land, and acquire lands in other ownerships within these areas to protect and promote public resource values 1 Forest-wide Standards and Guidelines apply See p IV-101	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>FACILITIES</u>	Road Construction	1. Provide and manage roads as needed to accomplish resource objectives.	
	Road Operation	1 Appropriate road use will be determined by project planning and design	
	FA&O Construction and Reconstruction	1 Forest-wide Standards and Guidelines apply See p IV-102 and 103	
<u>PROTECTION</u>	Fire Prevention	1. Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan	
	Fire Suppression	1 Implement fire suppression strategies that emphasize the protection of recreation facilities and values or other special values of each management area 2 Fire suppression tactics should emphasize the protection of life and property while minimizing the physical disturbance of the resources The use of all fire suppression resources is appropriate	
	Fire Hazard Abatement	1. Treatment of both activity generated and natural fuels is appropriate when coordinated with the scenic, recreational, or other special management objectives of the area 2 The protection of recreation and scenic values will be emphasized during the planning and implementation of these projects	
	Preattack Facilities Development	1 Develop only those preattack facilities that are compatible with the special visual and recreational values of the areas	
	Law Enforcement	1 Forest-wide Standards and Guidelines apply See p IV-103	
	Forest Pest Management	1 Suppress insects and diseases when outbreaks threaten managed resources and/or users	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p>RECREATION (continued)</p>	<p>Facility and Site Construction</p>	<p>1 Construction of new facilities should be limited to those which directly benefit and provide for appropriate public use of the feature or environment to which this prescription is directed</p>	<p>1 Design should be unobtrusive as possible and assure preservation of character-defining features of the site For historic sites, maintain the historic relationship between buildings, landscape features and open space</p>
	<p>Facility and Site Management</p>	<p>1. Provide maintenance to protect and preserve the values defined by this prescription</p>	<p>Minimize disturbance of the terrain. Design criteria should be developed that meet the sensitive values of this goal</p>
	<p>Use Administration</p>	<p>1 Manage recreation visitor use to prevent loss, damage, or displacement of resource values Prohibit uses in direct conflict with the goal of this prescription</p>	<p>1. Maintenance work should be in keeping with the Secretary of Interior's standards for rehabilitation of historic structures</p>
		<p>2. New permits for Recreational Special Use sites should be issued for compatible uses only Terminate or conform noncompatible uses on an opportunity basis</p>	<p>1 Pertinent protection clauses should be included in all special use permits to ensure preservation of the values to which this goal is directed</p>
	<p>Trail Reconstruction</p>	<p>1 Design and reconstruction should avoid specific features and characteristics of the environment to which the prescription is directed, and should correct existing conflicts between public use and the special features to be protected</p>	
	<p>Trail Construction</p>	<p>1 Provide access to those areas designated appropriate for public enhancement under this prescription Avoid construction where conflicts with the values of this prescription are unavoidable</p>	
	<p>Trail System Maintenance and Operation</p>	<p>1 Emphasize maintenance of those trails which provide appropriate public access to and use of the features defined by this prescription Consider closures where conflicts cannot be resolved.</p>	
<p>WILDERNESS</p>	<p>Wilderness Use Administration</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-70 through 78</p>	
<p>WILDLIFE AND FISH</p>	<p>Wildlife Surveys and Plans</p>	<p>1. Manage primary cavity excavators at 100 percent of the potential population level where snags do not pose threats to historical structures, features, facilities, or visitors</p>	
	<p>Non-Structural Habitat Improvement</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-83 and 84</p>	
	<p>Structural Habitat Improvement</p>	<p>1 Develop structural improvements only where compatible with the values of this prescription (i.e. to protect special botanical or zoological areas)</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RANGE</u>	Not Applicable to this Prescription		
<u>TIMBER</u>	<p><i>Regeneration Harvest</i></p> <p><i>Intermediate Harvest</i></p> <p>Silvicultural Examination and Prescription</p> <p>Reforestation</p> <p><i>Timber Stand Improvement</i></p> <p>Timber Sale Preparation and Timber Harvest Administration</p> <p>Nursery Management and Genetic Tree Improvement</p>	<p>1 No scheduled harvest. With the exception of the Tumwater Botanical Area, improvement cutting and salvage are allowed when compatible with, or to enhance the goal of this prescription. Unscheduled harvest may also take place to recover losses due to fire windthrow, insects or other catastrophes, where compatible with the prescription.</p> <p>1 Unscheduled harvest may take place to recover losses due to fire, windthrow, insects, or other catastrophes where compatible with the prescription.</p> <p>1 Forest-wide Standards and Guidelines apply See p. IV-92</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-92 and 93</p> <p>1 No precommercial thinning</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-93 and 94</p> <p>1 No special practice.</p>	
<u>WATER</u>	<p>Planning</p> <p>Improvement</p> <p>Administration and Management</p> <p>Rights and Use Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-94</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-94 and 96</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-94 and 95</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-95 and 96</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>AIR</u>	<p>Planning</p> <p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply. See p. IV-98</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-98</p>	
<u>MINERALS AND GEOLOGY</u>	<p>Locatable Minerals</p> <p>Leasable Energy Minerals</p> <p>Common Variety Minerals</p> <p>Recreational Mineral Activities</p>	<p>1 If cultural resources are encountered and it is determined that they are not presently owned or being used for mining or other purposes, assert public ownership by appropriately signing as Government Property</p> <p>2 Where legally permissible and logistically reasonable, remove unattached cultural resources to a visitor center for appropriate protection and interpretation</p> <p>1 Where existing laws and regulations do not adequately protect the area from entry and mining under the 1872 Mining Law, propose the area be withdrawn</p> <p>2 After the area has been withdrawn, confirm valid existing rights exist before approving any locatable mineral related activities</p> <p>1 If necessary to protect the resource and technically reasonable, recommend a no surface occupancy stipulation be attached to leases If the no-surface occupancy stipulation is unreasonable and significant unmitigatable impacts would occur from leasable mineral activity, recommend the area not be leased</p> <p>1 Do not permit the development of mineral material sites within these areas</p> <p>1 Allow only those uses that are compatible with the management objectives established for each individual site</p>	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		<p>1 Forest-wide Standards and Guidelines apply See p IV-99 and 100</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>LANDS</u>	<p>Special Use Management</p> <p>Right-of-Way Grants for Roads and Trails</p> <p>Federal Energy Regulatory Commission License and Permits</p> <p>Withdrawals, Modifications, and Revocations</p> <p>Property Line Location Property Boundary and Corner Maintenance</p> <p>Landownership Planning, Land Adjustment Planning, and All Adjustment Activities</p> <p>Rights-of-Way Cost-Share Agreements</p>	<p>1. Avoid locating transportation and utility corridors in these areas</p> <p>1. Provide appropriate access to inholders under then existing guidelines</p> <p>1 Recommend against these uses</p> <p>1 Consider withdrawal where mining activities may be detrimental to the resource and harmful effects cannot be avoided.</p> <p>1 Survey, mark, and post lines of all other ownerships within area not planned for acquisition</p> <p>1 Retain existing National Forest ownership, and acquire private inholdings within these areas to protect and promote public resource values</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-101</p>	<p>1 Consider impact to special values of the site and develop appropriate mitigation alternatives for that portion of the rights-of-way that is subject to Federal grant or cost sharing</p> <p>1 Make mineral classification investigation to support withdrawal.</p>
<u>FACILITIES</u>	<p>Road Construction</p> <p>Road Operation</p> <p>FA&O Construction and Reconstruction</p>	<p>1 Provide and manage roads as needed to accomplish resource objectives</p> <p>1 Encourage, accept, discourage, eliminate or prohibit road use as determined by project planning</p> <p>1. Maintenance and construction should be in keeping with the Secretary of Interior's standards for the rehabilitation of historic structures</p>	
<u>PROTECTION</u>	<p>Fire Prevention</p> <p>Fire Suppression</p>	<p>1. Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan.</p> <p>1. Implement fire suppression strategies that emphasize the protection of recreation facilities or other special values of each management area</p> <p>2 Fire suppression tactics should emphasize the protection of life and property while minimizing the physical disturbance of the resources The use of all fire suppression resources is appropriate</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>PROTECTION</u> (continued)</p>	<p>Fire Hazard Abatement</p>	<p>1 Treatment of both activity generated and natural fuels is appropriate when coordinated with the scenic, recreational, or other special values being emphasized in these management areas</p> <p>2. The protection of recreation values will be emphasized during the planning and implementation of these projects</p>	<p>1. Determine the occurrence and frequency of vandalism and theft at these areas, with corresponding investigations of any violations observed</p>
	<p>Preattack Facilities Development</p>	<p>1 Develop only those preattack facilities that are compatible with the special visual and recreational values of the areas</p>	
	<p>Law Enforcement</p>	<p>1 Provide law enforcement action as a means of protecting the special characteristics of the area</p>	
	<p>Forest Pest Management</p>	<p>1 Suppress insects and diseases when outbreaks threaten managed resources and/or users.</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives.</p>	

MANAGEMENT PRESCRIPTION: ST-1

TITLE: Scenic Travel - Retention

GOAL STATEMENT: To retain or enhance the viewing and recreation experiences along scenic travel routes.

DESCRIPTION: Development and permitted uses will meet the "Retention" Visual Quality Objective in foreground and middleground areas viewed from developed recreation sites and designated roads and trails. Developments and management activities within the allocation generally are not visually evident. The natural existing or established landscape will generally have vegetation on forested lands that is composed of large old growth trees in the overstory or in groves intermixed with a variety of age classes in the understory. The general perception of the landscape is a natural appearing environment.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1 Visual Quality Objective RETENTION</p>	<p>1 Landscape architectural input is recommended when planning an activity or constructing improvements</p> <p>2 Provide a diversity of vegetative species and age classes</p> <p>3 Where consistent with existing or predicted insect and disease conditions, strive to grow or maintain large (24-36" diameter) mature ponderosa pine, larch, and mixed conifer trees to an age of about 260 years. The number of trees left should retain form, line, color, and texture which are frequently found in the characteristic landscape. Changes in their qualities of size, amount, intensity, arrangement, and pattern should not be evident</p> <p>4 Regeneration cutting is generally by the extended shelterwood treatment. The design and viewing angle of created openings is more important than size. However, the seen area of openings will normally be three acres or less in foreground, and five acres or less in middleground</p> <p>5 Changes in form, line, color and texture resulting from management activities such as skid trails, landings, and prescribed burning should not be evident for more than one season</p> <p>6 New cutting units are designed to give the viewer the perception that not more than three percent of the foreground area in the viewshed (travel corridor) has been disturbed within any one decade</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u> (continued)</p>	<p>Recreation Planning and Inventory (continued)</p>	<p>1 Visual Quality Objective RETENTION (continued)</p> <p>2 Attempt to preserve indefinitely a few small patches of old growth timber for viewing by travelers Strive to retain a few scattered old growth or "character" trees throughout the corridor to add to visual variety</p> <p>3 Plan and develop recreation facilities and activities in conformity with applicable ROS class Semi-primitive motorized to Urban</p>	<p>7 New cutting units are designed to give the viewer the perception that not more than five percent of the middleground area in the viewshed has been disturbed</p> <p>8 Landings are to be located outside of seen areas or rehabilitated after the timber sale</p> <p>9 Utility right-of-way clearing are to blend with the natural vegetative pattern where possible</p> <p>10 Overhead utility lines are to be screened where possible, visible transmission towers will exhibit naturally harmonious colors</p> <p>11 Buildings shall exhibit natural harmonious colors</p> <p>12 Gravel, borrow, and stockpile areas are to be excluded from seen area, or rehabilitated after use</p> <p>13 Roads should not dominate natural patterns of form, line, color, and texture within clearcut areas one year after cutting</p> <p>14 Consider revegetating cut and fill slopes to the extent compatible with the surrounding area</p> <p>15 Landscape design should accompany all intersections of arterial and collector roads</p> <p>16 Fire protection measures should not dominate natural patterns of form, line, color, and texture</p> <p>17 Consider a level of prescribed fire, where appropriate, to maintain a natural appearance and enhance visual quality</p> <p>18 Rehabilitation measures are to be applied to landscapes where needed to improve the visual setting</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RECREATION</u> (continued)	<p>Cultural Resource Evaluation, Assessment and Protection</p> <p><i>Facility and Site Reconstruction and Construction</i></p> <p>Facility and Site Management</p> <p>Use Administration</p> <p>Trail Reconstruction and Construction</p> <p><i>Trail System Maintenance and Operation</i></p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-66</p> <p>1. <i>Forest-wide Standards and Guidelines</i> apply See p IV-67 and 68</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-68</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-68</p> <p>1 Plan and design trail construction and reconstruction projects to meet retention criteria when trails are viewed from roads and viewpoints</p> <p>2 Locate trails to take advantage of scenic viewpoints</p> <p>3 Issue permits and authorizations for activities or facilities compatible with the prescription goal</p> <p>1 <i>Maintain trail corridors</i> to provide a semiprimitive recreation experience</p>	
<u>WILDLIFE AND FISH</u>	<p>Wildlife Surveys and Plans</p> <p><i>Non-Structural and Structural Habitat Improvement</i></p>	<p>1 Develop openings or vistas where wildlife can be viewed in their natural habitat by the public.</p> <p>2 Manage primary cavity excavators at 60 percent of the potential population level.</p> <p>1. <i>Forest-wide Standards and Guidelines</i> apply See p IV-83 and 84</p>	
<u>RANGE</u>	<p>Range Planning and Inventory</p> <p><i>Range Non-Structural Improvements</i></p>	<p>1 Grazing of suitable range by livestock shall emphasize range management practices that favor scenic travel corridors</p> <p>2 Management of the range resource under this prescription will feature an intensive scheme of management</p> <p>1 Use only compatible species in range forage improvement projects</p>	<p>1 Management seeks to optimize production and utilization of forage allocated to livestock use consistent with maintaining the environment and providing for multiple use of the range</p> <p>1 Cultural practices may be selected and used to develop cost-effective methods for achieving improved forage supplies and uniform livestock distribution and forage use.</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RANGE</u> (continued)</p>	<p>Range Structural Improvements</p> <p>Range Structural Improvement Maintenance</p> <p>Range Administration and Management</p>	<p>1 Utilize the National Forest Landscape Management Handbook (USDA No 484) "Range" in the design and application of improvements</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-89</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-89</p>	<p>1. Fences and water developments are designed and applied to obtain relatively uniform livestock distribution and use of forage, and to maintain plant vigor</p>
<p><u>TIMBER</u></p>	<p>Regeneration Harvest</p> <p>Intermediate Harvest</p> <p>Silvicultural Examination and Prescription</p> <p>Reforestation</p> <p>Timber Stand Improvement</p> <p>Timber Sale Preparation and Timber Harvest Administration</p> <p>Nursery Management</p>	<p>1 Use shelterwood and small clearcuts subject to standards in Regional Plan, NFMA Regulations, and visual quality objectives</p> <p>1 Will generally use two commercial thinnings</p> <p>2. Remove dead and dying trees, as economical, from areas not scheduled for commercial harvest.</p> <p>1 Make examination prior to any activity and as required for certification of reforestation and thinning.</p> <p>1 Use compatible reforestation methods</p> <p>1 Use methods compatible with the goal</p> <p>1 Forest-wide Standards and Guidelines apply. See p IV-93 and 94</p> <p>1 Collect seed in sufficient quantities to meet program reforestation needs plus a sufficient reserve for natural disasters.</p>	<p>1 Extended shelterwood will be the predominant method</p> <p>2 Seed tree cut</p> <p>3 Small clearcuts</p> <p>1 Thin to maintain a minimum basal area that will utilize site potential and produce an economical harvest</p> <p>2 Salvage Sales.</p> <p>1 Stand examination</p> <p>1 Plant all nonstocked areas following regeneration harvest that are not expected to regenerate naturally within three years with desired species Use genetically superior stock as available. Interplant where needed Where feasible, use species suitable for long rotations (pine, larch, Douglas-fir)</p> <p>2 Perform site preparation compatible with the goal.</p> <p>3. Protect seedlings from animal damage where stocking level is threatened,</p> <p>1. Release regeneration overtopped by competing vegetation</p> <p>2. Fertilization will be used where needed to meet the objectives of this management</p> <p>1. Cone collection</p> <p>2 Seed certification.</p>

<u>SOIL</u>	Planning and inventory Improvement <i>Administration and Management</i>	1 Forest-wide Standards and Guidelines apply See p IV-96 1 Forest-wide Standards and Guidelines apply. See p IV-96 1. Forest-wide Standards and Guidelines apply See p IV-97	
<u>AIR</u>	Planning <i>Administration and Management</i>	1 Forest-wide Standards and Guidelines apply See p IV-98 1. Forest-wide Standards and Guidelines apply See p IV-98	
<u>MINERALS AND GEOLOGY</u>	Locatable Minerals	1 Withdrawals will be recommended in only a very few situations where it is determined that existing laws and regulations will not provide adequate protection for this prescription area 1 If existing laws and regulations do not provide adequate protection from mineral entry and mining under the 1872 mining law, propose the area be withdrawn 2 If the area is withdrawn, ensure valid existing rights exist before approving any locatable mineral related activities	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>MINERALS AND GEOLOGY</u> (continued)	Leasable Energy Minerals Common Variety Minerals Recreational Mineral Activities	1. If reasonable and necessary to maintain the integrity of the area, attach a no surface occupancy stipulation to leases 1 Allow mineral material disposal where removal of this resource is compatible with the objectives established for the area. 1. Forest-wide Standards and Guidelines apply See p IV-99	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		1. Forest-wide Standards and Guidelines apply See p IV-99 and 100	
<u>LANDS</u>	Special Use Management Right-of-Way Grants for Roads and Trails Federal Energy Regulatory Commission License and Permits Withdrawals, Modifications, and Revocations Property Line Location Property Boundary and Corner Maintenance Landownership Planning, Land Adjustment Planning, and All Adjustment Activities Rights-of-Way Cost-Share Agreements	1 Utility corridors are permitted subject to determination of need and requirements necessary to achieve visual objectives 1 Grant requests when necessary 1 Recommend only compatible uses 1. Withdrawals will be recommended only when necessary to meet the goal of the prescription 1 Survey, mark, and post all National Forest property lines 1. Make those land adjustments which will assist in achieving the goal of this prescription 1. Where applicable, use cost-share process to identify road location and standards compatible with the goal	
<u>FACILITIES</u>	Road Construction	1 Reduce the visual impact of roads 2 Fit the landscape with a minimum of landform and vegetation modification 3 Provide for flowing, rather than abrupt changes of grade and alignment Consolidate intersections	1 See National Forest Landscape Management Volume 2, Chapter 4, Roads, or revision.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>FACILITIES</u> (continued)</p>	<p>Road Construction (continued)</p>	<p>4 Provide viewing opportunities for a variety of landforms, waterforms, rockforms, and vegetation</p> <p>5 Provide viewing opportunities for the dominant landform feature</p> <p>6 Rehabilitate existing roads and material sources to meet the specified visual quality objective.</p> <p>7 To the extent practical, screen road from other viewing locations</p> <p>8. To the extent practical, locate roads on stable, fertile, and dark colored soils</p> <p>9 Reduce the visual contrasts of construction</p> <p>10 Utilize waste in positive ways.</p> <p>11 To the extent practical, shape borrow areas and abandoned roads</p> <p>12 Retain as many large rocks as practical within construction slopes.</p> <p>13 Conserve topsoil for revegetation areas</p> <p>14 Mulch with low contrast materials</p> <p>15. Strive for broken-faced rock cuts</p> <p>16 Retain the maximum amount of existing vegetation</p>	<p>1 Consider slope rounding</p> <p>2 Consider slope warping</p> <p>3. Use natural forms for ditches, swales, and channels</p> <p>1 Create screen and variety with mounds</p> <p>2 Fill depressions on uphill side of fills</p> <p>3 Fill cut sections of abandoned roads</p> <p>1 Minimal clearing beyond cut and fills</p> <p>2 Utilize treewells, retaining walls, and binwalls to reduce clearing width</p> <p>3 Allow for some fill over tree roots.</p> <p>4 Protect edges from equipment and blasting damage.</p> <p>5 Maintain the hydrologic regiment</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>PROTECTION</u>	Fire Prevention	1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan.	
	Fire Suppression	1. Implement fire suppression strategies that protect the scenic and recreational values being emphasized in the areas where these prescriptions are being used 2 Fire suppression tactics should minimize physical disturbance when feasible The use of water is preferred to physical disturbance of the site.	
	Fire Hazard Abatement	1. Treatment of both activity generated and natural fuels is appropriate when coordinated with the scenic and recreational values being emphasized in these management areas.	
	Preattack Facilities Development	1. Development of preattack facilities should occur only in areas of high fire frequency and when they do not detract from the scenic or recreational character of the landscape	
	Law Enforcement	1. Forest-wide Standards and Guidelines apply See p IV-103	
	Forest Pest Management	1 Suppress insects and diseases when outbreaks threaten managed resources and/or users. 2. Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives	

MANAGEMENT PRESCRIPTION: ST-2

TITLE: Scenic Travel - Partial Retention

GOAL STATEMENT: Provide a near natural appearing foreground and middleground along scenic travel corridors.

DESCRIPTION: Development and permitted uses will meet the "Partial Retention" Visual Quality Objective in the foreground and middleground viewed from developed recreation sites and designated roads and trails. The foreground of the main use routes will generally have vegetation that is composed of some large trees in the overstory or in groves intermixed with a variety of age classes in the understory. The middleground viewed areas from the main travel routes will generally have the perception of a slightly altered environment. The proposed uses and vegetation management within the allocation will be integrated with the natural landscape so that activities are visually subordinate to the characteristic landscape

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
RECREATION	Recreation Planning and Inventory	1 Visual Quality Objective. PARTIAL RETENTION	<p>1 Landscape architectural input is recommended on all planned activities or developments.</p> <p>2. Provide a diversity of vegetative species and age classes</p> <p>3 Where consistent with existing or predicted insect and disease conditions, strive to grow or maintain large mature ponderosa pine and larch to an age of about 260 years on dry ecosites. For mixed conifer trees to an age of about 180 years on wet ecosites. The number of trees left should retain form, line, color, and texture which are frequently found in the characteristic landscape. Changes in their qualities of size, amount, intensity, arrangement, and pattern must remain subordinate to the characteristic landscape.</p> <p>4 Regeneration cutting is generally by the extended shelterwood treatment. The design and viewing angle of created openings is more important than size. However, the seen area of openings will normally be 5 acres or less in foreground, and 15 acres or less in middleground.</p> <p>5 Changes in form, line color, and texture resulting from management activities such as skid trails, landings, and prescribed burning should not be evident for more than two seasons</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p>RECREATION (continued)</p>	<p>Recreation Planning and Inventory (continued)</p>	<p>1 Visual Quality Objective PARTIAL RETENTION (continued)</p>	<p>6 New cutting units are designed to give the viewer the perception that not more than five percent of the foreground area in the viewshed (travel corridor) has been disturbed within any one decade</p> <p>7 New cutting units are designed to give the viewer the perception that not more than seven and one-half percent of the seen middleground area in the viewshed has been disturbed within any one decade.</p> <p>8 Landings are to be located outside of seen areas or rehabilitated after timber sale.</p> <p>9. Utility right-of-way clearings are to blend with the natural vegetative pattern where possible.</p> <p>10.Overhead utility lines are to be screened where possible Visible transmission towers will exhibit naturally harmonious colors</p> <p>11 Buildings shall exhibit natural harmonious colors.</p> <p>12.Gravel, borrow, and stockpile areas are to be excluded from seen area or rehabilitated after use</p> <p>13 Roads should not dominate natural patterns of form, line, color, and texture within clearcut areas one year after cutting</p> <p>14 Consider revegetating cut and fill slopes to an extent compatible with the surrounding area</p> <p>15 Landscape design should accompany all intersections of arterial and collector roads.</p> <p>16 Fire protection measures should not dominate natural patterns of form, line, color, and texture</p> <p>17. Consider a level of prescribed fire where appropriate to maintain a natural appearance and enhance visual quality</p> <p>18 Rehabilitation measures are to be applied to landscapes where needed to improve the visual setting</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
RECREATION (continued)	Recreation Planning and Inventory (continued)	<p>2 Attempt to preserve indefinitely a few small patches of old-growth timber for viewing by travelers Strive to retain a few scattered old-growth or "character" trees throughout the corridor to add to visual variety.</p> <p>3 Plan recreation facilities and activities to conform to the Roaded natural ROS class criteria and harmonize with prescription goal</p>	
	Cultural Resource Evaluation, Assessment and Protection	1 Forest-wide Standards and Guidelines apply See p IV-66	
	Facility and Site Reconstruction and Construction	1 Forest-wide Standards and Guidelines apply See p IV-67 and 68	
	Facility and Site Management	1 Forest-wide Standards and Guidelines apply See p. IV-68	
	Use Administration	<p>1. Manage and maintain trail corridors to meet visual quality and recreation setting objectives of the prescription</p> <p>2 Issue permits when compatible with the goal.</p>	
	Trail Reconstruction and Construction	1. Plan and design trail construction and reconstruction projects to meet partial retention criteria as trail is viewed from roads or viewpoints	
	Trail System Maintenance and Operation	1 Forest-wide Standards and Guidelines apply See p IV-69	
<u>WILDLIFE AND FISH</u>	Wildlife Surveys and Plans	<p>1 Regulate human activities where necessary to prevent habitat degradation and wildlife harassment</p> <p>2 Develop openings or vistas where wildlife can be viewed in their natural habitat by the public</p> <p>3. Manage primary cavity excavators at 60 percent of the potential population level</p>	
Non-Structural and Structural Habitat Improvement	1 Forest-wide Standards and Guidelines apply See p IV- 83 and 84		

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RANGE</u></p>	<p>Range Planning and Inventory</p>	<p>1 Grazing of suitable range by livestock shall emphasize range management practices that are compatible with scenic travel corridors</p> <p>2 Management of the range resource under this prescription will feature an intensive scheme of management</p>	<p>1 Management seeks utilization of forage allocated to livestock. Cost effective management systems and techniques are designed and applied to obtain relatively uniform livestock distribution and use of forage, and to maintain plant vigor</p>
	<p>Range Non-Structural Improvements</p>	<p>1. Use only compatible species in range forage improvement projects</p>	<p>1. Cultural practices such as brush control, type conversion, fertilization, site preparation, and seeding of improved forage species may be used to improve quality and quantity of forage</p>
	<p>Range Structural Improvements</p>	<p>1. Utilize the National Forest Landscape Management Handbook (USDA No. 484) "Range" in the design and application of improvements</p>	<p>1. Cultural practices may be combined with fencing and water developments to implement complex grazing systems</p>
	<p>Range Structural Improvement Maintenance</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV-89</p>	
	<p>Range Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-89</p>	
<p><u>TIMBER</u></p>	<p>Regeneration Harvest</p>	<p>1 Use shelterwood and small clearcuts subject to standards in Regional Plan, NFMA Regulations, and visual quality objectives</p>	<p>1. Extended shelterwood will be the predominant method in the foreground</p>
	<p>Intermediate Harvest</p>	<p>1 Will generally use two commercial thinnings</p> <p>2. Remove dead and dying trees, as economical, from areas not scheduled for commercial harvest</p>	<p>1 Thin to maintain a minimum basal area that will utilize site potential and produce an economical harvest.</p> <p>1 Salvage Sales</p>
	<p>Silvicultural Examination and Prescription</p>	<p>1. Make examination prior to any activity and as required for certification of reforestation and thinning</p>	<p>1 Stand examination</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p>TIMBER (continued)</p>	<p>Reforestation</p>	<p>1. Use compatible reforestation methods.</p>	<p>1 Plant all nonstocked areas following regeneration harvest that are not expected to regenerate naturally within three years with desired species Use genetically superior stock as available. Interplant where needed. Where available, use species suitable for long rotations (pine, larch, Douglas-fir)</p> <p>2 Perform site preparation as required by site specifications.</p> <p>3. Protect seedlings from animal damage where stocking level is threatened</p>
	<p>Timber Stand Improvement</p>	<p>1 Use methods compatible with the goal.</p>	<p>1. Release regeneration overtopped by competing vegetation</p> <p>2 Fertilization will be used where needed to meet objectives of the management prescription</p>
	<p>Timber Sale Preparation and Timber Harvest Administration</p>	<p>1. Forest-wide Standards and Guidelines apply See p. IV- 93 and 94</p>	
	<p>Nursery Management</p>	<p>1. Collect seed in sufficient quantities to meet program reforestation needs plus a sufficient reserve for natural disasters</p>	<p>1 Cone collection</p> <p>2 Seed certification</p>
	<p>Genetic Tree Improvement</p>	<p>1 Implement the Forest Tree Improvement Program.</p>	<p>1 Select and maintain superior trees</p> <p>2 Collect seed from superior trees.</p>
<p>WATER</p>	<p>Planning</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 94</p>	
	<p>Improvement</p>	<p>1 Forest-wide Standards and Guidelines apply. See p. IV- 94 and 96</p>	
	<p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-94 and 95</p>	
	<p>Rights and Use Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV- 95 and 96</p>

Suppress insects and diseases when outbreaks threaten managed resources and/or users Use suppression methods that minimize site disturbance</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives</p>	

MANAGEMENT PRESCRIPTION: UC-1

TITLE: Utility Corridors

GOAL STATEMENT: Provide and manage utility corridors to accommodate energy transmission needs

DESCRIPTION: This prescription is applicable to existing and potential utility and transmission corridors. It includes the land directly under and adjacent to the pipeline or powerline facility (clearing limits). Compatible facilities are combined in the same corridor whenever possible. Resource uses, such as grazing, and dispersed recreation activities, such as camping, mushroom and berry picking, Christmas tree cutting, etc., may be compatible in some areas.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1. Visual Quality Objective MAXIMUM MODIFICATION</p> <p>2 Plan recreation activities to conform to the appropriate ROS class criteria within the range of Roaded modified to Urban</p>	<p>1 A visual analysis is required to blend activities with the naturally established landscape.</p> <p>2 Rehabilitation measures may be applied to the landscape where needed to improve the visual setting.</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV-67 and 68</p>	
	<p>Facility and Site Management</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV-68</p>	
	<p>Use Administration</p>	<p>1 Manage dispersed recreation activities to emphasize uses that are compatible with utility corridor objectives</p>	
	<p>Trail Reconstruction and Construction</p>	<p>1 Forest-wide Standards and Guidelines apply. See p. IV-68 and 69</p>	
	<p>Trail System Maintenance and Operation</p>	<p>1 Forest-wide Standards and Guidelines apply See p. IV-69</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>WILDLIFE AND FISH</u>	Wildlife Surveys and Plans Non-Structural and Structural Habitat Improvements	1 Management for primary cavity excavators is incompatible with this prescription 1 Forest-wide Standards and Guidelines apply See p. IV-83 and 84	
<u>RANGE</u>	Range Planning and Inventory Range Non-Structural and Structural Improvements Range Structural Improvement Maintenance Range Administration and Management	1 Suitable range will be available for allocation to livestock and managed at the same intensity level as adjoining prescription 1 Forest-wide Standards and Guidelines apply See p IV-89 and 92 1 Forest-wide Standards and Guidelines apply. See p IV-89 1 Forest-wide Standards and Guidelines apply. See p IV-89	
<u>TIMBER</u>	Regeneration Harvest Intermediate Harvest Silvicultural Examination and Prescription Reforestation Timber Stand Improvement Timber Sale Preparation and Timber Harvest Administration Nursery Management and Genetic Tree Improvement	1 No scheduled harvest. Use improvement and salvage cutting when compatible with the prescription goal 1 Forest-wide Standards and Guidelines apply See p IV-92 1. Forest-wide Standards and Guidelines apply See p IV-92 1 May be reforested to grow products compatible with the goal 1 Forest-wide Standards and Guidelines apply See p IV-93 1 Forest-wide Standards and Guidelines apply See p IV-93 and 94 1 No special practice	
<u>WATER</u>	Planning Improvement Administration and Management Rights and Use Management	1 Forest-wide Standards and Guidelines apply See p IV-94 1 Forest-wide Standards and Guidelines apply. See p IV-94 and 96 1 Forest-wide Standards and Guidelines apply. See p IV-94 and 95 1 Forest-wide Standards and Guidelines apply See p IV-95 and 96	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>SOIL</u>	Planning and Inventory Improvement Administration and Management	1. Forest-wide Standards and Guidelines apply See p IV-96 1 Forest-wide Standards and Guidelines apply See p IV-96 1. Forest-wide Standards and Guidelines apply See p IV-97	
<u>AIR</u>	Planning Administration and Management	1. Forest-wide Standards and Guidelines apply. See p IV-98 1. Forest-wide Standards and Guidelines apply See p IV-98	
<u>MINERALS AND GEOLOGY</u>	Locatable Minerals Leaseable Energy Minerals Common Variety Minerals Recreational Mineral Activities	1. Ensure permittee's improvements are appropriately protected or impacts are mitigated 1. Same as for Locatable Minerals 1. Same as for Locatable Minerals 1 Forest-wide Standards and Guidelines apply See p IV-99	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		1. Forest-wide Standards and Guidelines apply. See p. IV-99 and 100	
<u>LANDS</u>	Special Use Management Right-of-Way Grants for Roads and Trails Federal Energy Regulatory Commission License and Permits Property Line Location Property Boundary and Corner Maintenance	1 Forest-wide Standards and Guidelines apply See p IV-100 1. Provide appropriate access to inholders under then existing guidelines 2 Utility right-of-way clearing is to blend with the natural vegetative pattern where possible 1 These areas will have priority for new applications 2 Overhead utility lines are to be screened where possible, visible transmission towers require naturally harmonious colors 1 Forest-wide Standards and Guidelines apply See p. IV-100	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>LANDS</u> (continued)</p>	<p>Landownership Planning, Land Adjustment Planning, and All Adjustments Activities</p> <p>Rights-of-Way Cost-Share Agreements</p>	<p>1. Forest-wide Standards and Guidelines apply See p. IV-100 and 101</p> <p>1. Proposed cost share access road locations and standards will be coordinated with corridor managers</p>	
<p><u>FACILITIES</u></p>	<p>Road Construction</p> <p>Road Operation</p> <p>FA&O Construction and Reconstruction</p>	<p>1 Provide and manage roads as needed to accomplish resource objectives</p> <p>1. Encourage, accept, discourage, eliminate or prohibit road use as determined by project planning and design</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-102 and 103</p>	
<p><u>PROTECTION</u></p>	<p>Fire Prevention</p> <p>Fire Suppression</p> <p>Fire Hazard Abatement</p> <p>Preattack Facilities Development</p> <p>Law Enforcement</p> <p>Forest Pest Management</p>	<p>1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan.</p> <p>1 Implement fire suppression strategies that emphasize the protection of the facilities associated with the utility transmission corridors</p> <p>2. Fire suppression tactics should emphasize the protection of life and property The use of all fire suppression resources is appropriate.</p> <p>1 Treatment of both activity generated and natural fuels is appropriate when the activities enhance the management objectives of the utility corridor</p> <p>1. Forest-wide Standards and Guidelines apply. See p IV-103</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-103</p> <p>1 Suppress insects and diseases when outbreaks threaten managed resources and integrity of structures</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource objectives</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Facility and Site Management</p>	<p>1 Facilities and campsites, where appropriate, will be managed to minimize social and biological resource impacts</p>	<p>1 Campsites with fire rings may be retained and managed to provide campsite opportunities and help direct users to specific sites capable of withstanding use impacts</p> <p>2 Sites in excess of user need or sites showing unacceptable change in social or biological condition may be obliterated and rehabilitated. Appropriate management actions to correct the situation are described in Appendix E</p>
	<p>Use Administration</p>	<p>1 Management actions will be implemented to control or restrict visitor use when user impacts result in a change in biological or social resource conditions that approach limits of acceptable change. Appropriate management actions are explained in Appendix E</p> <p>2 Wilderness Ranger contacts with recreation visitors for educational, instructive and informative purposes will generally be made outside wilderness or in high visitor use areas. Contacts inside wilderness will be in accord with the managerial setting for each WROS class</p> <p>3 Permits or authorizations to providers of commercial recreation opportunities will be issued when appropriate to the goals of wilderness management and where compatible with the WROS class and existing visitor use of an area</p>	<p>1. Monitoring will measure the specific parameters of key indicators of biological or social conditions</p> <p>2 Monitoring measurements will be conducted in areas receiving significant visitor use, at least every five years to record trends of change</p>
	<p>Trail Reconstruction and Construction</p>	<p>1 Trail construction and reconstruction will occur to protect biological resource values and to meet wilderness management objectives</p> <p>2 Trail reconstruction or construction specifications will meet trail objectives and conform with specifications of the appropriate WROS class in which the trail is located</p>	<p>1 Trail location and design standards will be compatible with WROS class criteria.</p> <p>2 No trails will be constructed in pristine WROS Class areas</p> <p>3 Trails may be relocated into Primitive WROS class areas if necessary to solve resource management problems. However, the solitude and remoteness of a primitive area will not be sacrificed to distribute or accommodate more use</p> <p>1 Specific trail objectives identifying the role, purpose, destination, level, and type of use and expectations of the users will be established for each trail.</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RECREATION</u> (continued)	Trail System Maintenance and Operation	1 The trail system will be maintained and operated as appropriate to trail objectives and the appropriate WROS class for the area accessed by the trail	
<u>WILDLIFE AND FISH</u>	Wildlife Surveys and Plans Non-Structural and Structural Habitat Improvement	1 Manage primary cavity excavators at 100 percent of the potential population level 1 Forest-wide Standards and Guidelines apply See p. IV-83 and 84	
<u>RANGE</u>	Range Planning and Inventory Range Non-Structural Improvements Range Structural Improvements Range Structural Improvement Maintenance Range Administration and Management	1. Allotment Management Plans will define the specific allocation of forage resources, the grazing management system, and the monitoring necessary to achieve wilderness management objectives and maintain range conditions within acceptable limits of change 2 Management of the range resource under this prescription will feature a stewardship (Level B) management scheme There will be no increased range use. 3 Where conflicts are identified on suitable range, these will be minimized through range management practices that emphasize management needs 1. Manage existing plants only 1 Utilize the National Forest Landscape Management Handbook (USDA No 484) "Range" in the design and application of improvements. 1 Reconstruct, relocate, or eliminate range improvements that are not compatible 1. Forest-wide Standards and Guidelines apply See p IV-89	1 Monitoring will be conducted in allotment management at frequencies that will record and document vegetative conditions and trends 1 Level B Management - Management controls livestock numbers so that livestock use is within present grazing capacity Distribution is achieved through riding, herding and/or salting. 1. Improvements are minimal and constructed only to the extent needed to cost effectively maintain stewardship of the range resource in the presence of grazing.
<u>TIMBER</u>	Not applicable to this prescription		

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>WATER</u>	<p>Planning</p> <p>Improvement</p> <p>Administration and Management</p> <p>Rights and Use Management</p>	<p>1. Educate visitors to maintain water quality</p> <p>2. Water resource improvements shall be consistent with the Wilderness Act.</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-94 and 96</p> <p>1 Forest-wide Standards and Guidelines apply. See p IV-94 and 95</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-95 and 96</p>	
<u>SOIL</u>	<p>Planning and Inventory</p> <p>Improvement</p> <p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV-96</p> <p>1 Rehabilitate degraded sites caused by management activities or visitor use.</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-97</p>	<p>1 Rehabilitation will utilize only materials and techniques that are compatible with the wilderness</p>
<u>AIR</u>	<p>Planning</p> <p>Administration and Management</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-98</p> <p>1 Protect air quality related values (AQRV's) within all Class I areas</p>	<p>1. Management activities which are ongoing within the area will be conducted in a manner which protects Air Resource quality to a standard that meets or exceeds the guidance provided by the Clean Air Act.</p>
<u>MINERALS AND GEOLOGY</u>		<p>1 Even though these areas are withdrawn, allow prospecting in accordance with Section 4(d)(2) of the Wilderness Act. This may include private parties, State Agencies, the US Geological Survey or the US Bureau of Mines</p> <p>2 If recently located mining claims are encountered, inform the claimant that the area is no longer subject to location</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>FACILITIES</u>	Road Construction	1 No roads will be constructed or maintained except that reasonable access will be granted to landlocked Inholders under the then prevailing guidelines	
<u>PROTECTION</u>	<p>Fire Prevention</p> <p>Fire Suppression</p> <p>Fire Hazard Abatement</p> <p>Preattack Facilities Development</p> <p>Law Enforcement</p> <p>Forest Pest Management</p>	<p>1. Implement a low intensity fire prevention program as outlined in the Forest's Fire Management Action Plan.</p> <p>1. All naturally occurring fires will initially be considered prescribed fires. A timely analysis will be conducted and if the situation does not comply with all elements of the prescription it will be declared a wildfire.</p> <p>2. All wildfires will be suppressed utilizing an appropriate suppression strategy. Suppression tactics that minimize physical disturbance will be used.</p> <p>3. All human caused fires will be considered wildfires.</p> <p>1. Naturally occurring fires burning within prescription will be managed in an attempt to replicate the natural fire cycle.</p> <p>2. Management ignited fire may be used to replicate the natural fire cycle where ignitions are infrequent or to protect adjacent values.</p> <p>1. The development of Preattack facilities is not appropriate.</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-103</p> <p>1. Suppress insects and diseases when outbreaks threaten resources in adjacent areas. Favor biological controls when available.</p> <p>2. Survey pest populations as a management strategy for adjacent resource areas.</p>	

WS-1 AND WS-2

MANAGEMENT PRESCRIPTION: WS-1

TITLE: Scenic River (Proposed)

GOAL STATEMENT: Preserve the Scenic River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

DESCRIPTION: This prescription is for application to those river segments on the Forest that are free of impoundments, and have largely primitive watersheds or shorelines but are accessible by road in places.

MANAGEMENT PRESCRIPTION: WS-2

TITLE: Recreational River (Proposed)

GOAL STATEMENT: Preserve the Recreational River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System

DESCRIPTION: This prescription is for application to those river segments on the Forest that are readily accessible by road or railroad, may have some development along their shorelines, and may have undergone some impoundment or diversion in the past.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RECREATION</u>	Recreation Planning and Inventory	1 Visual Quality Objective RETENTION	<p>1 Landscape architectural input is required when planning an activity or constructing improvements</p> <p>2 Provide a diversity of vegetative species and age classes.</p> <p>3 Where consistent with existing or predicted insect and disease conditions, strive to grow or maintain large (24-36" diameter) mature ponderosa pine, larch, and mixed conifers to an age of about 260 years. The amount of trees left should retain form, line, color, and texture which are frequently found in the characteristic landscape. Changes in their qualities of size, amount, intensity, direction, and pattern should not be evident</p> <p>4 Regeneration cutting is generally by the extended shelterwood treatment. The design and viewing angle of created openings is more important than size. However, the seen area of openings generally should not exceed three acres in the foreground, and five acres in the middleground</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u> (continued)</p>	<p>Recreation Planning and Inventory (continued)</p>	<p>1. Visual Quality Objective. RETENTION (continued)</p>	<p>5 Activities creating form, line, color, and texture changes such as slid trails, red needles, and black ground from burning, should not be evident for more than one season</p> <p>6. New cutting units are designed to give the viewer the perception that not more than three percent of the foreground area in the viewshed has been disturbed within any one decade.</p> <p>7 New cutting units are designed to give the viewer the perception that not more than five percent of the middleground area in the viewshed has been disturbed</p> <p>8 Landings are to be located outside of seen areas or rehabilitated after timber sales</p> <p>9 Utility right-of-way clearings are to blend with the natural vegetative pattern</p> <p>10 Overhead utility lines are to be screened where possible, visible transmission towers will exhibit naturally harmonious colors</p> <p>11 Buildings shall exhibit natural harmonious colors</p> <p>12 Gravel, borrow and stockpile areas are to be excluded from the seen area or be rehabilitated after use</p> <p>13. Roads must not dominate natural patterns of form, line, color, texture within clearcut areas one year after cutting</p> <p>14 Revegetate cut and fill slopes to the extent compatible with the surrounding area</p> <p>15 Landscape design is to accompany all intersections of arterial and collector roads</p> <p>16 Fire protection measures shall not dominate natural patterns of form, line, color, and texture.</p> <p>17 Consider a level of prescribed fire where appropriate to maintain natural appearance and enhance visual quality</p> <p>18 Rehabilitation measures are to be applied to the landscape where needed to improve the visual setting</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u> (continued)</p>	<p>Recreation Planning and Inventory (continued)</p> <p>Cultural Resource Protection</p> <p>Facility and Site Reconstruction</p> <p>Facility and Site Construction</p> <p>Facility and Site Management</p> <p>Use Administration</p> <p>Trail Reconstruction</p> <p>Trail Construction</p> <p>Trail System Maintenance and Operation</p>	<p>2. Plan recreation activities and facility development to conform to the appropriate ROS class criteria within the range of Roded natural to urban.</p> <p>3 Motorized use is appropriate when compatible with the management goal.</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-66</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-67 and 68</p> <p>1 New facilities should be screened from scenic rivers</p> <p>1 Forest-wide Standards and Guidelines apply. See p IV-68</p> <p>1 Encourage recreation use and activities to the setting of the Recreational or Scenic River designation</p> <p>2. Issue permits for land uses and activities that are compatible with the prescription goal</p> <p>1. Forest-wide Standards and Guidelines apply See p. IV-68</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-68 and 69</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-69</p>	
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p> <p>Non-Structural Habitat Improvement</p> <p>Structural Habitat Improvement</p>	<p>1. Manage primary cavity excavators at 60 percent of the potential population level.</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-83 and 84</p> <p>1 Forest-wide Standards and Guidelines apply See p. IV-83 and 84</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>RANGE</u>	<p>Range Planning and Inventory</p> <p>Range Non-Structural Improvements</p> <p>Range Structural Improvements</p> <p>Range Structural Improvement Maintenance</p> <p>Range Administration and Management</p>	<p>1. Grazing of suitable range by livestock shall emphasize range management practices that favor potential Recreational and Scenic Rivers</p> <p>2 Management of the range resource under this prescription will feature a Level C scheme of management</p> <p>3. Intensive cultural practices will not be used</p> <p>1. Use only compatible species in range forage improvement projects</p> <p>1 Utilize the National Forest Landscape Management Handbook (USDA No 484) "Range" in the design and application of improvements</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-89</p> <p>1 Forest-wide Standards and Guidelines apply See p IV-89</p>	<p>1 Level C Management - Management seeks utilization of forage allocated to livestock</p> <p>1 Cost effective management systems and techniques including fences and water developments are designed and applied to obtain relatively uniform livestock distribution and use of forage and to maintain plant vigor</p>
<u>TIMBER</u>	<p>Planning and Inventory</p> <p>Regeneration Harvest</p> <p>Intermediate Harvest</p> <p>Silvicultural Examination and Prescription</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-92</p> <p>1 Use shelterwood and small patchcuts subject to standards in Regional Plan, NFMA Regulations and visual quality objectives</p> <p>2 Entiat River from Cottonwood trailhead to Wilderness boundary will have no scheduled harvest</p> <p>1 Remove dead and dying trees, as economical, from areas not scheduled for commercial harvest</p> <p>2 Will generally use two commercial thinnings</p> <p>3 Entiat River from Cottonwood trailhead to Wilderness boundary will have no scheduled harvest</p> <p>1 Make examination prior to any activity and as required for certification of reforestation and thinning</p>	<p>1 Extended shelter wood will be the predominant method.</p> <p>2 Seed tree cut</p> <p>3 Small clearcuts</p> <p>1 Salvage Sales</p> <p>2 Thin to maintain a minimum basal area that utilize site potential and produce an economical harvest</p> <p>1 Stand examination</p>

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>TIMBER</u> (continued)</p>	Reforestation	1 Use compatible reforestation methods	<p>1. Plant all nonstocked areas following regeneration harvest, unless natural regeneration is expected within 3 years. Use genetically superior stock as available. Interplant where needed. Use species suitable for long rotations (pine, larch, Douglas-fir)</p> <p>2 Perform site preparation as required by site specifications.</p> <p>3 Protect seedlings from animal damage.</p>
	Timber Stand Improvement	1. Use methods compatible with the goal	
	Timber Sale Preparation and Timber Harvest Administration	1 Forest-wide Standards and Guidelines apply See p IV-93 and 94	
	Nursery Management	1 Collect seed in sufficient quantities to meet program reforestation needs plus a sufficient reserve for natural disasters.	<p>1 Cone collection</p> <p>2 Seed certification</p>
	Genetic Tree Improvement	1 Implement the Forest Tree Improvement Program	<p>1. Select and maintain superior trees</p> <p>2. Collect seed from superior trees</p>
	Reforestation Animal Control	1. Forest-wide Standards and Guidelines apply. See p IV-92 and 93	
<p><u>WATER</u></p>	Planning	1 Forest-wide Standards and Guidelines apply. See p IV-94	
	Improvement	1 Forest-wide Standards and Guidelines apply See p IV-94 and 96	
	Administration and Management	1 Forest-wide Standards and Guidelines apply See p IV-94 and 95

<u>MINERALS AND GEOLOGY</u>	<p>Locatable Minerals</p> <p>Leaseable Energy Minerals</p> <p>Common Variety Minerals</p> <p>Recreation Minerals Activities</p>	<p>1. Forest-wide Standards and Guidelines apply until the river component is designated part of the Wild and Scenic River system Mining activities shall then be subject to such regulations as the Secretary of Agriculture may prescribe</p> <p>1 Same as Locatable Minerals</p> <p>1. Same as Locatable Minerals</p> <p>1 Same as Locatable Minerals</p>	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		<p>1. Forest-wide Standards and Guidelines apply. See p IV-99 and 100</p>	
<u>LANDS</u>	<p>Special Use Management</p> <p>Right-of-Way Grants for Roads and Trails</p> <p>Federal Energy Regulatory Commission License and Permits</p> <p>Withdrawals, Modifications, and Revocations</p> <p>Property Line Location Property Boundary and Corner Maintenance</p> <p>Landownership Planning, Land Adjustment Planning, and All Adjustment Activities</p>	<p>1 Avoid locating transportation and utility corridors in these areas</p> <p>1 Provide appropriate access to inholder under then existing guidelines</p> <p>1. Recommend only compatible uses</p> <p>1 Mineral withdrawal will not be recommended upon classification.</p> <p>1 Property lines of those inholdings not to be acquired will be surveyed, marked and posted to full standard</p> <p>1 Identify those lands needed in National Forest ownership to meet management goals</p> <p>2 Identify those lands which can be left in other ownerships, or would contribute to the proposed management goals in other ownership</p> <p>3 Use partial takings to maximum extent consistent with management goals</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<u>LANDS</u> (continued)	Rights-of-Way Cost-Share Agreements	1 Forest-wide Standards and Guidelines apply See p IV-101	
<u>FACILITIES</u>	Road Construction	1 Provide and manage roads to accomplish resource objectives	1. Scenic Rivers Roads may occasionally bridge the rivers Short stretches of conspicuous roads or longer stretches of inconspicuous or well screened roads are allowed 2 Recreational Rivers' Roads may parallel on one or both river banks There can be several bridge crossings and numerous river access points
	Road Operation	1 Appropriate road use will be determined by project planning and design	
	FA&O Construction and Reconstruction	1. Forest-wide Standards and Guidelines apply See p IV-102 and 103	
<u>PROTECTION</u>	Fire Prevention	1 Implement a high intensity fire prevention program as outlined in the Forest's Fire Management Action Plan	
	Fire Suppression	1 Implement fire suppression strategies that attempt to protect the scenic and recreationa values being emphasized in the areas where these prescriptions are being used 2. Fire suppression tactics should minimize physical disturbance when feasible The use of water is preferred to physical disturbance of the site	
	Fire Hazard Abatement	1 Treatment of both activity generated and natural fuels is appropriate when coordinated with the scenic and recreational values being emphasized in these management areas	
	Preattack Facilities Development	1. Development of preattack facilities should occur only in areas of high fire frequency and when they do not detract from the scenic or recreational character of the landscape	
	Law Enforcement	1 Forest-wide Standards and Guidelines apply. See p IV-103	
	Forest Pest Management	1 Suppress insect and disease outbreaks to preserve recreational character and adjacent resources. Avoid degradation of water quality 2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource goals. 3. Inspect defective trees for unacceptable hazard to users and facilities.	

MANAGEMENT PRESCRIPTION: WS-3

TITLE: Wild River (proposed)

GOAL STATEMENT: Preserve the Wild River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

DESCRIPTION. This prescription is applicable to those river segments that are free of impoundments and generally inaccessible except by trail, with watersheds or shoreline essentially primitive and waters unpolluted. These represent vestiges of primitive America.

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>RECREATION</u></p>	<p>Recreation Planning and Inventory</p>	<p>1. Visual Quality Objective. PRESERVATION</p> <p>2 Plan recreation activities that conform to the primitive and Semi-primitive non-motorized ROS classes</p> <p>3 Motorized use may be appropriate depending upon current uses and adjacent allocations</p>	<p>1 Fire protection measures should not dominate natural patterns of form, line, color, and texture</p> <p>2 Consider a level of prescribed fire where appropriate to maintain natural appearance and enhance visual quality</p> <p>3 Rehabilitation measures are to be applied to the landscape where needed to improve the visual setting</p>
	<p>Cultural Resource Evaluation, Assessment and Protection</p>	<p>1 Forest-wide Standards and Guidelines apply. See p IV-66</p>	
	<p>Facility and Site Reconstruction and Construction</p>	<p>1 Where practical locate new structures outside of the zone</p>	
	<p>Facility and Site Management</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV-68</p>	
	<p>Use Administration</p>	<p>1 Forest-wide Standards and Guidelines apply See p IV-68</p>	
	<p>Trail Reconstruction and Construction</p>	<p>1. Forest-wide Standards and Guidelines apply See p IV-68 and 69</p>	
<p><u>WILDERNESS</u></p>	<p>Wilderness and Wild River Mgmt</p>	<p>1 In case of conflict between wilderness management and Wild River management, the more restrictive prescription shall apply</p>	

WS-3

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>WILDLIFE AND FISH</u></p>	<p>Wildlife Surveys and Plans</p> <p>Non-Structural and Structural Habitat Improvement</p>	<p>1. Manage primary cavity excavators at 100 percent of the potential population level</p> <p>1. Forest-wide Standards and Guidelines apply. See p. IV-83 and 84</p>

<u>MINERALS AND GEOLOGY</u>	<p>Locatable Minerals</p> <p>Leasable Energy Minerals</p> <p>Common Variety Minerals</p> <p>Recreational Minerals</p>	<p>1. Forest-wide Standards and Guidelines apply until the component is designated part of the system Upon designation the river segment and one-quarter mile of the bank of the river are withdrawn from all forms of appropriation under the mining laws and mineral leasing laws</p> <p>2 After inclusion in the system as a Wild segment, ensure prior valid existing rights exist before approving mining claim activities</p> <p>1 Same as Locatable Minerals</p> <p>2. After inclusion in the system as a Wild segment, do not issue any mineral leases Ensure prior valid existing rights exist before approving any leasable mineral activities.</p> <p>1 Same as Locatable Minerals</p> <p>2. After inclusion as part of the system, do not allow disposal of common variety minerals.</p> <p>1 Meet Forest-wide Standards and Guidelines until the area is designated a Wild River, then allow only those activities that are in keeping with the management objectives of the river.</p>	
<u>RURAL COMMUNITY AND HUMAN RESOURCES</u>		<p>1 Forest-wide Standards and Guidelines apply See p IV-99 and 100</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>LANDS</u></p>	<p>Special Use Management</p> <p>Right-of-Way Grants for Roads and Trails</p> <p>Federal Energy Regulatory Commission License and Permits</p> <p>Withdrawals, Modifications, and Revocations</p> <p>Landownership Planning, Land Adjustment Planning, and All Adjustment Activities</p> <p>Rights-of-Way Cost-Share Agreements</p>	<p>1 Avoid locating transportation and utility corridors in these areas</p> <p>2 Issue permits when compatible with the goal</p> <p>1 Provide appropriate access to inholders under then existing guidelines</p> <p>1. Section 7 of the Wild and Scenic Rivers Act of Oct 2, 1968 (P L 90-542, 82 Statue 906, as amended), prohibits the licensing of the construction of any project works within a Wild, Scenic, or Recreational River area</p> <p>1 Lands classified as "Wild" segments will be withdrawn from mineral entry under the Wild and Scenic Rivers Act</p> <p>1. Identify those lands needed in National Forest ownership to meet management goals</p> <p>2 Identify those lands which can be left in other ownerships, or would contribute to the proposed management goals in other ownership.</p> <p>3 Use partial takings to maximum extent consistent with management goals</p> <p>1. Forest-wide Standards and Guidelines apply See p IV-101</p>	
<p><u>FACILITIES</u></p>	<p>Road Construction</p> <p>Road Operation</p> <p>FA&O Construction and Reconstruction</p>	<p>1 No roads will be constructed or maintained except that reasonable access will be granted to landlocked inholders under the then prevailing guidelines</p> <p>1. Appropriate road use will be determined by project planning and design</p> <p>1 Not applicable to this prescription</p>	

RESOURCE ELEMENT	MANAGEMENT ACTIVITY	STANDARDS AND GUIDELINES	MANAGEMENT PRACTICE
<p><u>PROTECTION</u></p>	<p>Fire Prevention</p>	<p>1. Implement a low intensity fire prevention program as outlined in the Forest's Fire Management Action Plan</p>	
	<p>Fire Suppression</p>	<p>1 All naturally occurring fires will initially be considered prescribed fires. A timely analysis will be conducted and if the situation does not comply with all elements of the prescription it will be declared a wildfire.</p>	
		<p>2 All wildfires will be suppressed utilizing an appropriate suppression strategy. Suppression tactics which minimize physical disturbance will be used.</p>	
	<p>Fire Hazard Abatement</p>	<p>3 All human caused fires will be considered wildfires</p> <p>1. Naturally occurring fires burning within prescription will be managed in an attempt to replicate the natural fire cycle</p> <p>2 Management ignited fire may be used to replicate the natural fire cycle where ignitions are infrequent or to protect adjacent values</p>	
	<p>Preattack Facilities Development</p>	<p>1 The development of Preattack facilities is not appropriate.</p>	
	<p>Law Enforcement</p>	<p>1. Forest-wide Standards and Guidelines apply See p. IV-103</p>	
	<p>Forest Pest Management</p>	<p>1. Suppress insect and disease outbreaks when necessary to protect river character or adjacent resources.</p> <p>2 Utilize Integrated Pest Management strategies to prevent unacceptable pest damage and meet resource goals</p>	

CHAPTER V

IMPLEMENTATION OF THE FOREST PLAN

A. INTRODUCTION

Implementation of the Wenatchee National Forest Plan requires moving from an existing management program, with a budget and “targets” for accomplishment, to a new management program with a budget, goals, and objectives that provide a different way of addressing the issues and concerns people have voiced about management of the Wenatchee National Forest. This Forest Plan establishes the direction for the Forest for the next ten to fifteen years, when used *in conjunction with Forest Service Manuals and the Pacific Northwest Regional Guide*

This chapter explains how management of the Wenatchee National Forest moves from the Current Direction and Existing Situation to the Proposed Action, all described in the Final Environmental Impact Statement. The following sections describe aspects of implementation that are influenced by previous management activities and objectives, the relationship between project planning and this Forest Plan, the goals of and requirements for monitoring and evaluation, and the circumstances which could require the Plan to be amended or revised.

B. IMPLEMENTATION DIRECTION

Implementation of the Forest Plan occurs through identification, selection, scheduling and execution of management practices to meet management direction provided in the Plan. Implementation also involves responding to proposals by others for use and/or occupancy of National Forest System lands.

Project Planning

Implementation and action plans designed to give implementation guidance for management, protection, and development activities may be developed under the “umbrella” of this Forest Plan. These may become part of the implementation package for the Forest.

Examples of these plans include:

- Forest Trail Plan**
- Wilderness Action Plans**
- Range Allotment Management Plans**
- Fire Management Action Plans**
- Municipal Watershed Plans**
- Land Adjustment Action Plans**
- Corridor Viewshed Plans**
- Tree Improvement Plan**
- Best Management Practices**
- Forest Development Transportation Plan**
- Pacific Crest National Scenic Trail
Comprehensive Plan**
- Off Road Vehicle Plan**
- Law Enforcement Plan**
- Noxious Weed Action Plan**
- Species Management Guides**

Project Scheduling

The schedule of proposed projects is contained in Appendix A of this document. This appendix contains activity schedules. These activity schedules represent a pool of possible projects from which implementation schedules (specific, funded projects) are developed in conjunction with funding approvals. Listings of possible projects to meet or accelerate the ten-year management activities schedules are maintained by the unit managers. These listings will routinely change as projects are implemented, or are removed from the listings for other reasons and as new projects take their place. Projects are scheduled in response to the planned outputs of goods and services and the annual budgeting process.

Consistency with Other Instruments

This Forest Management Plan serves as the single land management plan for the Wenatchee National Forest with the exception of the Alpine Lakes Management Plan, which is incorporated into this Forest Plan by reference. All other land management plans are replaced by the direction in this plan; a list of plans superseded by this plan are:

Land Management Plans

- The Chelan Unit Plan 1976
- The Kittitas Unit Plan 1979

Ranger District Multiple Use Plans

- Naches Ranger District Multiple Use Plan 11/10/61
- Tieton Ranger District Multiple Use Plan

Timber Management Plans

- Wenatchee National Forest 12/16/63 as amended
- Snoqualmie National Forest 3/3/69 as amended (Naches-Tieton Working Circle)

If direction in this Plan is found not to agree with the direction contained in the Alpine Lakes Management Plan, the Alpine Lakes Management Plan will take precedence for the Alpine Lakes Management Unit.

All outstanding and future permits, contracts, cooperative agreements and other instruments for occupancy and use of lands included in the Forest Plan will be brought into compliance with this Plan, subject to the valid existing rights of the parties involved; this will be done within three years of the date of this plan.

Budget Proposals

The Plan's scheduled projects are translated into multi-year program budget proposals that identify needed expenditures. The schedule is used for requesting and allocating the funds needed to carry out the planned management direction. Upon approval of a final budget for the Forest, the annual program of work is finalized and carried out. Accomplishment of the annual program is the incremental implementation of the management direction of the Forest Plan. Outputs and activities in individual years may be significantly different from those shown in Chapter IV depending on final budgets.

Environmental Analysis

Projects and activities permitted through this Forest Plan are subject to analysis to assure compliance with the National Environmental Policy Act (NEPA), as they are planned for implementation. If the environmental analysis for a project shows that: (1) the management area prescriptions, standards and guidelines can be complied with and (2) little or no environmental effect is expected beyond that identified and documented in the Forest Plan Final EIS, the analysis will probably result in a finding of no significant impact. An analysis file and/or a project file will be available for public review. The analysis will not necessarily be documented in the form of an environmental assessment or environmental impact statement. If the analysis shows neither the activity nor the resulting impacts to be significant, and the activity conforms to the list of categories in the Forest Service Manual, then it can result in a Categorical Exclusion.

The environmental analysis process provides a tie between implementation and monitoring of this Forest Plan. Reviews of Environmental Assessments and Environmental Impact Statements assure that the Standards and Guidelines contained in the Plan are identified in the formulation of alternatives for permitted activities (Implementation Monitoring).

C. MONITORING AND EVALUATION PROGRAM

The Monitoring Plan, Table V-1, identifies the key activities and outputs to be tracked during implementation of this plan to ensure that activities reasonably conform to the Management Area direction, and that outputs satisfy the objectives of the Plan.

It is not intended to spell out all monitoring that is occurring or may occur on the Forest in the future. Currently, many activities are being monitored to comply with administrative and legal responsibilities. However, this monitoring is not essential for the purposes mentioned above. Only those items that are essential and sensitive enough for the purposes of this plan will be addressed in the monitoring plan.

The specific objectives of the Monitoring and Evaluation Program are to determine whether:

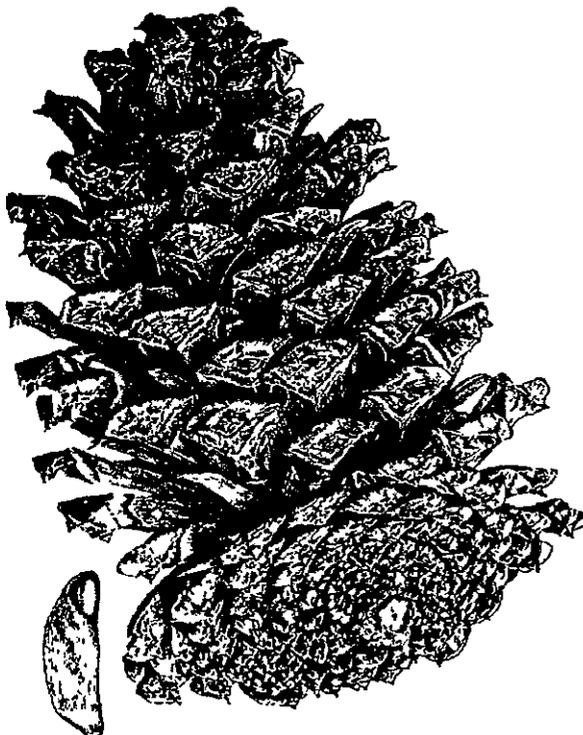

1. Planned goals and objectives are achieved.
2. Programs and activities address existing and emerging public issues and management concerns.
3. Management Standards and Guidelines are being followed.
4. Management Standards and Guidelines effectively maintain environmental quality.
5. Workforce, resource and cost assumptions used in projecting output and impacts are correct.
6. Activities on intermingled and adjacent lands managed by other agencies or land owners are affecting management of the Forest.
7. Research and information needs beyond that identified in Chapter II of this Plan is needed.
8. The Forest Plan needs to be amended or revised.
9. Intensity of monitoring is commensurate with the risks, costs and values involved in meeting Plan objectives.

Monitoring and evaluation each have a distinctly different purpose and scope. In general, monitoring is designed to gather the data necessary for evaluation. During evaluation, data provided through monitoring are analyzed and interpreted. This process will provide periodic summary data necessary to determine if implementation is within the bounds of the Forest Plan.

At intervals established in this Plan, implementation will be evaluated to determine how well objectives have been met, how accurate effects and cost projections are, and how closely management standards and guidelines have been applied. Based upon this evaluation of the monitoring results, the Interdisciplinary Team shall recommend to the Forest Supervisor such changes in management direction, revisions, or amendments to the Forest Plan as deemed necessary. The action prescribed by the Forest Supervisor will depend upon the significance of the monitoring results. The magnitude of the change from predicted conditions is an important factor, as is the risk associated with the change. Procedures prescribed by the National Environmental Policy Act will be followed by the Forest Supervisor in determining the appropriate action.

The data collected during monitoring will be evaluated using the Decision Flow Diagram shown in Figure V-1. As indicated in the diagram the results of the evaluation lead to recommendations of the following types:

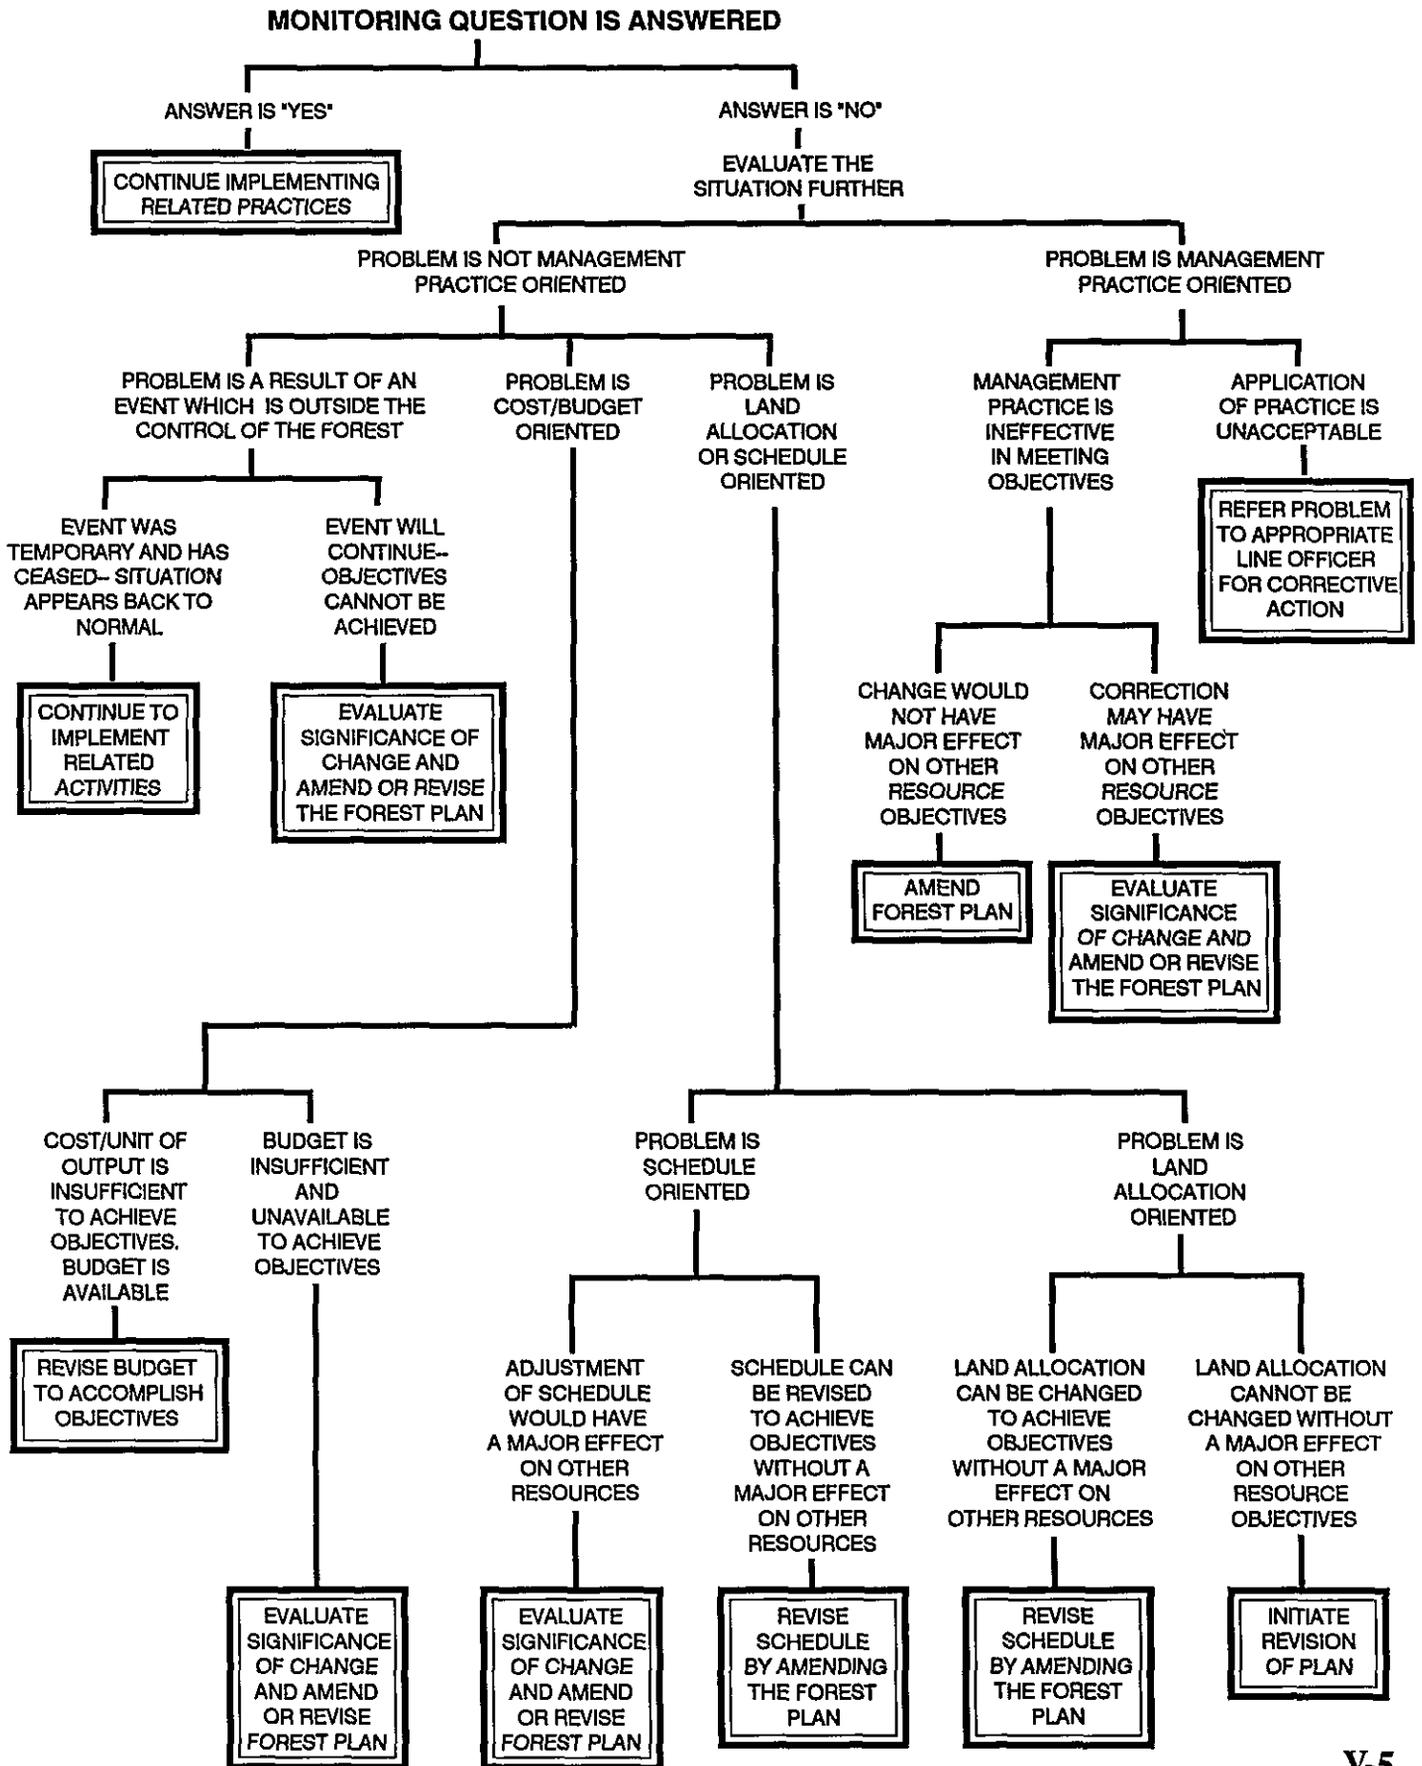

1. Referring problems to the appropriate line officer for action.
2. Modifying the management practice or direction as a plan amendment.
3. Modifying the land allocation as a plan amendment.
4. Revising the schedule of outputs.
5. Revising the cost/unit output.
6. Initiating revision of the Plan.

The document resulting from the use of the Decision Flow diagram constitutes the evaluation report. As applicable, the following will be included in each evaluation report:

1. A quantitative estimate of performance comparing outputs and services with those projected in the Forest Plan.
2. Documentation of measured effects, including any changes in productivity of the land.
3. Unit costs associated with carrying out the planned activities as compared with unit costs estimated during Forest Plan development.
4. Recommendations for changes.
5. A list of needs for evaluation of management systems and for alternative methods of management.
6. A list of additional research needed to support the management of the Forest.
7. Identification of additional monitoring needs to facilitate achievement of the monitoring goals.

**FIGURE V-1
DECISION FLOW DIAGRAM**

The Monitoring Plan consists of the following components:

1. **Monitoring Item** - Identification of the item or resource component being monitored.
2. **Actions/Effects** - A specific statement of what will be examined.
3. **Units** - Units to be measured or produced.
4. **Variability Permitted** - The variation from the expected outputs, or activities that is permitted before corrective action or further evaluation is taken.
5. **Suggested Methods** - The specific method on how the monitoring will be accomplished.
6. **Who will Monitor** - The person or persons responsible for evaluating or coordinating the monitoring activity.
7. **Frequency** - The time period showing how often the item will be monitored.
8. **Location of Data** - The file or data storage system in which the monitoring results will be kept.
9. **Annual Cost** - The cost included is the minimum anticipated cost of conducting the monitoring for that item. Amount in () indicates the amount currently being spent on the monitoring item.

Appendix F displays detailed Monitoring Worksheets which are summarized in the following Table V-1.

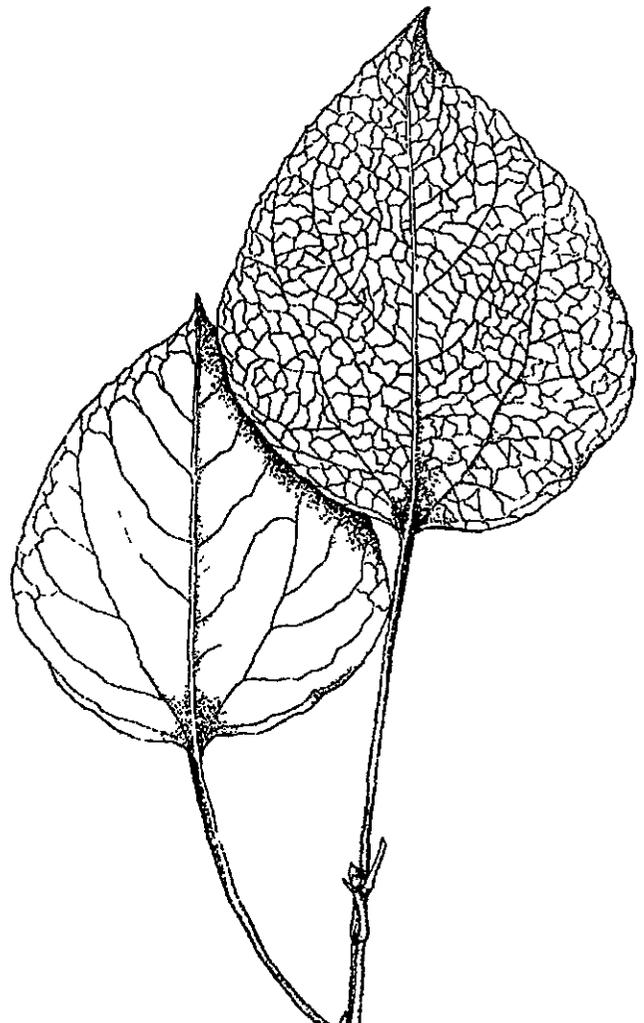

TABLE V-1
MONITORING PLAN

MONITORING ITEM	ACTIONS/EFFECTS TO BE MONITORED	UNITS	VARIABILITY PERMITTED	SUGGESTED METHODS	WHO WILL MONITOR	FREQUENCY AND REPORT	LOCATION OF DATA	ANNUAL COST
Standards & Guidelines, General	Are S&G being implemented? Do S&G achieve expectations?	All Forest Acres	No deviation See other worksheets	2 stage Mgt. Team review Comparisons w/ stage 2	Planning Staff	Annual w/ 5-yr rpt.	S O. Files	\$10,000 (5,000)
ROS Classes & Semi-prim Setting	Compliance with Prescribed ROS Direction	All Forest Acres	Change to a more dev set than Plan	Review random proj. in field	Rec. Staff, DRs.	Annual w/ 5-yr rpt	District & S O. Files	\$ 3,500 (1,000)
Forest trails, inc. ORV	Trails give variety of experiences. Use w/o impair. Trails w/ mixed use meet user expectations	Miles of Trail	Miles const. w/in 25% ann & 10% decade Features on stable to improv. trend Inc. trend of letters w/ conflict.	Project accomp rpts Review of Use Records & Public Comments	Rec. Staff, DRs Rec. Staff	Annual w/ 5-yr rpt	Project Files & RIM District & SO files	\$15,000 (7,500)
Developed Recreation Facilities	Available Facilities meet demand Site mgt serves public & protect resource	Acres in RE-1 trend	Exceeds 60% of PAOT Declining sites	Estimate use at sites Inspect rec	Rec Staff, DRs	Annual w/ 5-yr rpt	RIM Reports	\$18,000 (12,000)
Dispersed Areas	Dispersed sites meet visitor expectations Sites across ROS	All Forest Acres	Declining trend ROS not met	Field Review	Rec Staff, DRs	Annual w/ 5-yr rpt	District & S.O. Files	\$12,000 (6,000)
Wild, Scenic and Rec Rivers	Maintain suitability of recom. rivers	All WS-1 WS-2, & WS-3 River Acres	No Loss of eligibility	Project Reviews	Rec. Staff DRs	Annual w/ 5-yr rpt	Project Files	\$ 7,000 (0)
Visual Resource Objectives	Cumulative activities meet desired obj.	Total Forest Acres	Met in all	NEPS & field review Viewshed analysis	Timber, Visual Res. Staff	Annual 5-yr	EAs & files	\$14,000 (5,000)
Wilderness	Maintain LAC Standard	All Wilderness	Various depending on LAC	Field Monitoring & Photopoint	Rec. Staff	Annually w/ 5-yr rpt	District and S.O. Files	\$33,000 (10,000)
Protection of Cultural Resources	Protect characteristics Find reasonably locatable sites	Number of Sites	10% damaged Significant find during project	Field inspect Proj. Surv.	Rec.Staff	Annual Ongoing	Project Files	\$10,000 (3,000)
Rehab of Cultural sites	Rehab & stable sites	Number of Sites	Significant site damaged	Field review	Rec Staff	Annual	SO files	\$ 3,750 (0)

D. AMENDMENT AND REVISION

The Forest Plan incorporates legal mandates, professional judgement and the public's stated concerns into a future vision of the Forest. It charts a path for getting there by developing management goals and objectives and translating them into management direction in the form of standards and guidelines for management areas on the Forest. National Forest planning is a dynamic process, and the products -- Forest Plans -- are similarly dynamic. Forest Plans can and should be modified if conditions warrant. As management goals are applied on the ground or as new information is learned about resources, the Plan's goals and objectives, or activities the goals generate, may no longer be appropriate. In such instances, activities may be tailored to fit the resource, or planning objectives as stated in the Plan may be amended. Plans do not apply direction in site-specific management activities. It would be unrealistic to try to identify, analyze and schedule the numerous diverse projects or activities that occur on a National Forest. Instead, this type of site-specific planning occurs at the project-level planning stage, such as allotment management planning.

The Forest Supervisor may amend the Forest Plan. Based on an analysis of the objectives, standards, and other contents of the Forest Plan, the Forest Supervisor shall determine whether a proposed amendment would result in a significant change in the Plan. If the change resulting from the proposed amendment is determined to be significant, the Forest Supervisor shall follow the same procedure as that required for development and approval of a Forest Plan. If the change resulting from the amendment is determined not to be significant for the purposes of the planning process, the Forest Supervisor may implement the amendment following appropriate public notification and satisfactory completion of NEPA procedures.

The Forest Plan shall ordinarily be revised on a ten-year cycle or at least every 15 years. It also may be revised whenever the Forest Supervisor determines that conditions or demands in the area covered by the Plan have changed significantly or when changes in Resource Planning Act policies, goals, or objectives would have a significant effect on Forest level programs. In the monitoring and evaluation process, the interdisciplinary team may recommend a revision of the Forest Plan at any time. Revisions are not effective until considered and approved in accordance with the requirements for the development and approval of the Forest Plan. The Forest Supervisor shall review the conditions on the land covered by the Plan at least every five years to determine whether conditions or demands of the public have changed significantly.

GLOSSARY

ACRE EQUIVALENT - When applied to habitat improvement or improvement structures this term reflects overall habitat benefits derived. It reflects the zone of influence of the habitat improvement for the target species. For example, a single water development for upland game birds occupies very little space but has an acre equivalent of 160 because it serves 160 acres of bird habitat. A single water structure for big game has a value of 640 because it has a larger zone of influence for the more mobile big game animals.

ACRE-FOOT (AF) - A water measurement term equal to the amount of water that would cover an area of one acre to a depth of one foot (43,560 cubic feet).

ACTIVITY - Actions, measures, or treatments undertaken which directly or indirectly produce, enhance, or maintain forest outputs and rangeland outputs, or achieve administrative and environmental quality objectives. Forest Service activity definitions, codes, and units of measure are contained in the Management Information Handbook (FSM 1309.11).

AIRSHED - A geographical area that, because of topography, meteorology, and climate, shares the same air

ALLOCATED FUNDS - Funds from sources other than Congressionally appropriated funds. Allocated funds include the Senior Community Service Program, brush disposal (BD), Knutson-Vandenberg cooperative deposits (K-V), and State of Washington funds for trails from the Interagency Committee for Outdoor Recreation

ALLOWABLE SALE QUANTITY (ASQ) - The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan for a time period specified by the plan. This quantity is usually expressed on an annual basis as the "average annual allowable sale quantity." (36 CFR 219.3)

ALTERNATIVE - One of several policies, plans, or projects proposed for decision making

AMENITY - An object, feature, quality, or experience that gives pleasure or is pleasing to the mind or senses. Amenity value is typically used in land use planning to describe those resource properties for which market values (or proxy values) are not or cannot be established.

AMS - An abbreviation of Analysis of the Management Situation.

ANADROMOUS FISH - Those species of fish that mature in the ocean and migrate into streams to spawn. Salmon, steelhead, and shad are examples.

ANALYSIS AREA - A delineated area of land subject to analysis of (1) responses to proposed management practices in the production, enhancement, or maintenance of forest and rangeland outputs and environmental quality objectives and (2) economic and social impacts.

ANALYSIS OF THE MANAGEMENT SITUATION (AMS) - A determination of the ability of the planning area to supply goods and services in response to society's demand for those goods and services.

ANIMAL UNIT MONTH (AUM) - The quantity of forage required by one mature cow (1,000 pounds), or the equivalent for one month, based upon average daily forage consumption of 26 pounds of dry matter per day (800 pounds/month).

APPROPRIATE SUPPRESSION RESPONSE - The planned strategy for suppression action (in terms of kind, amount, and timing) on a wildfire which most efficiently meets fire management direction under current and expected burning conditions. It may range in objective from prompt control to one of containment or confinement.

APPROPRIATED FUNDS - Funds from the U. S. Treasury, which Congress has authorized the Forest Service to obligate. This is the sum of operational, capital investment, and backlog costs.

AQUATIC ECOSYSTEMS - Streams, channels, lakes, marshes or ponds, and the plant and animal communities they support.

ASQ - An abbreviation of Allowable Sale Quantity.

AREA OF SPECIES MANAGEMENT GUIDES - A contiguous area where management direction is the same.

ARTERIAL ROADS - See Roads.

AUM'S - An abbreviation of Animal Unit Months.

BACKGROUND - In visual management terminology, refers to the visible terrain beyond the foreground and middleground where individual trees are not visible but are blended into the total fabric of the forest stand (also see Foreground and Middleground).

BASAL AREA - The cross-sectional area of a stand of trees measured at breast height. The area is expressed in square feet.

BASE TIMBER SALE SCHEDULE - A Timber Sale Schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and this planned sale and harvest for any decade is not greater than long-term sustained yield capacity. (36 CFR 219.3).

BASIN - The largest regional hydrologic unit for the Wenatchee National Forest (Columbia River Basin)

BENCHMARK LEVELS - The outputs and costs for managing the Forest at certain levels of management so that a comparison could be made on costs, values, and effects.

BENEFIT - (Value) Inclusive terms used to quantify the results of a proposed activity, program or project expressed in monetary or nonmonetary terms.

BENEFIT-COST RATIO - Measure of economic efficiency computed by dividing total discounted primary benefits by total discounted economic costs.

BEST MANAGEMENT PRACTICES (BMP's) - A practice or combination of practices determined by the state that are the most effective and practical (including technological, economic and institutional considerations) means of preventing or reducing the amount of pollution generated by non-point sources to a level compatible with water quality goals.

BF - An abbreviation of board feet.

BIG GAME - Those species of large mammals normally managed for sport hunting.

BIOLOGICAL CONTROL - A method to control wildlife or insect populations and noxious weeds or tree diseases through the use of applied biology.

BIOLOGICAL GROWTH POTENTIAL - The average net growth attainable in a fully stocked natural forest stand. (36 CFR 2193)

BIOLOGICAL POTENTIAL - The maximum production of a selected organism that can be attained under optimum management.

BIOMASS - The total quantity (at a given time) of living organisms of one or more species per unit of space (species biomass), or the total quantity of all the species in a biotic community (community biomass).

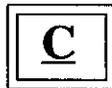

BOARD FOOT - The amount of wood equivalent to a piece of wood one foot by one foot by one inch thick.

BRITISH THERMAL UNIT (BTU) - The amount of heat required to raise the temperature of one pound of water one degree Fahrenheit.

BROADCAST BURN - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for a reduction of fuel hazard or as a silvicultural treatment, or both.

BRUSH - A growth of shrubs or small trees usually of a type undesirable to livestock or timber management.

BUREAU OF LAND MANAGEMENT (BLM) - An agency within the Department of the Interior with land management responsibility for the Public Domain lands.

CAPABILITY - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices at a given level of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, soils and geology, as well as the application of management practices, such as silviculture or protection from fire, insects, and disease. (36 CFR 219.3)

CEQ - An abbreviation of Council on Environmental Quality.

CF - An abbreviation of cubic feet.

CHARGEABLE TIMBER VOLUME - The timber removed from regulated forest land that contributes to meeting the allowable sale quantity.

CLASS I (II & III) STREAMS - See Stream Class.

CLEARCUTTING - The harvesting in one cut of all trees in an area for the purpose of creating a new, even-aged stand. The area harvested may be a patch, stand, or strip large enough to be mapped or recorded as a separate age class in planning for sustained yield.

CLIMAX - The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition.

CLIMAX SPECIES - Those species that dominate the forest stand in either numbers per unit area or biomass at climax.

CODE OF FEDERAL REGULATIONS (CFR) - The listing of various regulations pertaining to management and administration of the National Forest

COLLECTOR ROAD SYSTEM - See Roads.

COMMERCIAL FOREST LAND (CFL) - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn from timber management by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils, productivity, or watershed conditions; and (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking of young trees can be attained within 5 years after final harvest.

COMMERCIAL THINNING - Cutting by mean of sales of products (poles, posts, pulpwood, etc.) in immature forest stands to improve the quality and growth of the remaining stand.

COMMODITY - A transportable resource product with commercial value; all resource products which are articles of commerce.

COMPACTION - The packing together of soil particles by forces at the soil surface, resulting in increased soil density.

CONCERN - A point, matter, or question raised by management that must be addressed in the planning process.

CONFINE - To restrict the fire spread within a predetermined area principally by use of natural or preconstructed barriers or environmental conditions. Suppression action may be minimal and limited to surveillance under appropriate conditions.

CONGRESSIONALLY CLASSIFIED AND DESIGNATED AREAS - Areas that require Congressional enactment for their establishment, such as National Wilderness Areas, National Wild, Scenic, and Recreational Rivers, and National Recreation Areas.

CONIFER - A group of cone-bearing trees, mostly evergreen, such as pine, spruce, fir, etc.

CONSUMPTIVE USE - Those uses of a resource that reduce its supply.

CONTAIN - To surround a fire, and any spot fires therefrom, with control line as needed, which can reasonably be expected to check the fire's spread under prevailing and predicted conditions. The normal suppression tactic is indirect attack, allowing the fire to burn to human-made or natural barriers with little or no mop-up.

CONTROL - To complete the control line around a fire and around any spot fires therefrom and any interior islands of vegetation to be saved. Firefighters will also burn out any unburned area adjacent to the fire side of the control line, and cool down all hot spots that are immediate threats to the control line until the line can reasonably be expected to hold under foreseeable conditions. The normal tactic is direct attack on the fire, if possible, and mop-up to extinguish all fire.

CORE AREA - (As related to spotted owl.) An area encompassing at least 300 contiguous acres of old growth forest suitable for nesting and reproduction. The area consists of a portion of the territory required by a pair of owls, the nest site, and principal roost areas.

CORRIDOR - A linear strip of land identified for the present or future location of transportation or utility rights-of-way. (36 CFR 219.3)

COST EFFICIENCY - The usefulness of specified inputs (costs) to produce specified outputs (benefits). In measuring cost efficiency, some outputs, including environmental, economic, or social impacts, are not assigned monetary values but are achieved at specified levels in the least cost manner. Cost efficiency is usually measured using present net value, although use of benefit-cost ratios and rates of return may be appropriate. (36 CFR 219.3)

COST, CAPITAL INVESTMENT - The cost of man made structures, facilities, or improvements in natural resources used as inputs in production processes to produce outputs over one or more planning periods.

COST-EFFECTIVE - Achieving specified outputs or objectives under given conditions for the least cost.

COST, FIXED - A cost that is committed for the time horizon of planning or the decision being considered. Fixed costs include fixed ownership requirements, fixed protection, short-term maintenance and long-term planning and inventory costs.

COST, OPERATIONAL - Costs associated with administering and maintaining National Forest facilities and resource programs. This includes appropriated funds only.

COST, VARIABLE - A cost that varies with the level of controlled outputs in the time horizon covered by the planning period or decisions being considered.

COUNCIL ON ENVIRONMENTAL QUALITY (CEQ) - An advisory council to the President established by the National Environmental Policy Act of 1969. It reviews Federal programs for their effect on the environment, conducts environmental studies, and advises the President on environmental matters

COVER/FORAGE RATIO - The mixture of cover and forage areas on a unit of land expressed as a ratio (e.g. deer summer range goal may be a 60/40 ratio).

CREATED OPENING - Created openings are openings in the Forest created by the silvicultural practices of shelterwood regeneration cutting at the final harvest, clearcutting, seed tree cutting, or group selection cutting.

CRITICAL HABITAT - For threatened or endangered species, the specific areas within the geographical area occupied by the species (at the time it is listed, in accordance with provisions of Section 4 of the Endangered Species Act) on which are found those physical or biological features essential to the conservation of the species. This habitat may require special management considerations or protecting. Protection may also be required for additional habitat areas outside the geographical area occupied by the species at the time it is listed based upon a determination of the Secretary of the Interior that such areas are essential for the conservation of the species.

CRITICAL MINERALS - Minerals essential to the national defense, but whose procurement, while difficult in case of war, is less serious than those of Strategic Minerals.

CUBIC FOOT (CF) - A unit of measure with the dimensions of one foot by one foot by one foot thick

CULMINATION OF MEAN ANNUAL INCREMENT (CMAI) - The point where the mean annual growth of a timber stand ceases to increase prior to decline. Mean annual increment is expressed in cubic feet measure and is based upon expected growth according to the management intensities and utilization standards assumed in accordance with 36 CFR 219.16.

CULTURAL RESOURCES - Any site, structure, or object, or group of sites, structures, or objects that have been made, modified, or used by man in the past.

CUMULATIVE EFFECTS - The combined effects of two or more management activities. The effects may be related to the number of individual activities, or to the number of repeated activities on the same piece of ground. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

DECISION CRITERIA - Essentially the rules or standards used to evaluate alternatives. They are measurements or indicators that are designed to assist a decision maker in identifying a preferred choice from an array of possible alternatives.

DEFERRED ROTATION - Any grazing system which provides for a systematic rotation of the delay or discontinuance of livestock grazing on an area to provide for plant reproduction establishment or restoration of vigor

DEMAND - The amount of output that users are willing to take at specific price, time period, and conditions of sale.

DEPARTURE - A schedule which deviates from the principle of nondeclining flow of timber harvest by exhibiting an increase in cutting levels above sustainable levels followed by a planned decrease below sustainable levels in the timber sale and harvest schedule at some time in the future.

DESIGNATED AREA (AIR QUALITY) - Those areas delineated in the Oregon and Washington Smoke Management Plans as principal population centers of air quality concern.

DESTINATION RESORT - A recreation resort designed for multi-day use in contrast to single day use

DEVELOPED RECREATION SITE - Distinctly defined area where facilities are provided for concentrated public use, e.g. campgrounds, picnic areas, boating sites, and ski areas.

DIAMETER BREAST HIGH (DBH) - The diameter of a standing tree at a point 4 feet, 6 inches from ground level.

DISCOUNT RATE - An interest rate that represents the cost or time value of money in determining the present value of future costs and benefits.

DISCOUNT RATE, REAL - A discount rate adjusted to exclude the effects of inflation

DISCOUNTING - An adjustment, using a discount rate, for the value of money over time so that costs and benefits occurring in the future are reduced to a common time, usually the present, for comparison.

DISPERSED RECREATION - Outdoor recreation that takes place outside developed recreation sites or the Wilderness.

DIVERSITY - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan. (36 CFR 219.3)

DRAINAGE PATTERN - The configuration or arrangement of streams within a drainage basin or other area.

ECONOMIC EFFICIENCY - The usefulness of inputs (costs) to produce outputs (benefits) and effects when all costs and benefits that can be identified and valued are included in the computations. Economic efficiency is usually measured using present net value, though use of benefit/cost ratios and rates of return may sometimes be appropriate

ECONOMIC IMPACT - The positive or negative change in economic conditions, including distribution and stability of employment and income in affected local, regional, and national economies, which directly or indirectly results from an activity, project or program.

ECOSYSTEM - An interacting system of organisms considered together with their environment; for example, marsh, watershed, and lake ecosystems.

EDGE - The boundary between two or more elements of the environment; e.g. field and woodland.

EDGE CONTRAST - A qualitative measure of the difference in structure of two adjacent vegetated areas; for example, low, medium, or high edge contrast.

EFFECTS - Environmental consequences as a result of a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and are later in time or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include population growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems.

The terms "Effects" and "Impacts" as used in this statement are synonymous. Effects may be ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems),

aesthetic quality, historic, cultural, economic, social, or health related, whether direct, indirect, or cumulative Effects resulting from actions may have both beneficial and detrimental aspects, even if on balance the agency believes that the overall effects will be beneficial (40 CFR 1508 8).

ENDANGERED SPECIES - Any species of animal or plant which is in danger of extinction throughout all or a significant portion of its range. An endangered species must be designated by the Secretary of Interior as endangered in accordance with the Endangered Species Act of 1973.

ENVIRONMENTAL ANALYSIS - An analysis of alternative actions and their predictable short and long-term environmental effects, incorporating the physical, biological economic, social, and environmental design factors and their interactions.

ENVIRONMENTAL ASSESSMENT - A concise public document required by the regulations implementing the National Environmental Policy Act.

EROSION - The wearing away or detachment of the land surface by running water, wind, ice, or other geological agents, including such processes as gravitation creep.

EROSION (ACCELERATED) - Erosion much more rapid than normal, primarily as a result of the influence or the activities of man.

EROSION (NATURAL) - Wearing away of the earth's surface by water, ice, or other natural agents under natural environmental conditions of climate, vegetation, etc., undisturbed by human activity.

ESCAPED FIRE - A fire which has exceeded, or is anticipated to exceed, preplanned initial action capabilities or the fire management direction

ESCAPE COVER - Usually vegetation dense enough to hide an animal; used by animals to escape from potential enemies.

ESSENTIAL HABITAT - Areas designated by the Forest Service Regional Forester that possess the same characteristics of critical habitat as those designated by the Secretary of the Interior or Commerce

EVEN-AGED MANAGEMENT - The application of a combination of actions that results in the creation of forest stands composed of trees of essentially the same age Managed even-aged forests are characterized by a distribution of stands of varying ages (and, therefore, tree sizes throughout the forest area). The difference in age between trees forming the main canopy level of a stand usually does not exceed 20 percent of the age of the stand at harvest rotation age. Regeneration in a particular stand is obtained in a short period at or near the time that a stand has reached the desired age or size for regeneration and is harvested. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands. (36 CFR 219.3)

EVEN-FLOW - Maintaining a relatively constant supply of timber from decade to decade.

EXCLUSION AREA - An area having a statutory prohibition to rights-of-way for linear facilities or corridor designation.

EXPECTED BURNED ACREAGE - The expected annual number of acres burned by fire size class and intensity level for a given program option or budget level.

EXTENDED SHELTERWOOD - This is a variation of the shelterwood system design to provide for other resources such as wildlife or scenery considerations. The term extended is used to denote the retention of the old stand for a longer period than is necessary or, in many cases, desirable for maximum growth of the new stand.

EXTIRPATION - Extermination.

FINAL REMOVAL - The removal of the last seed bearers or shelter trees after regeneration is established under a shelterwood system.

FIRE MANAGEMENT ANALYSIS ZONE - The geographically delineated areas into which the planning unit is divided for the purpose of fire management analysis. The delineation is based upon common fire-behavior characteristics which is the “corner stone” for fire planning and evaluation of fire effects.

FIRE MANAGEMENT DIRECTION - The direction provided by an interdisciplinary team for each separate management area on the Forest. It includes guides by management area for long-term maximum burn acreages, specifying fire size and intensity, which would not adversely affect attainment of resource targets or outputs. In addition, it provides guidelines on desired residue profiles and the use of fire to meet resource prescriptions.

FIRE PROGRAM OPTION - A given program mix funded at a given program level. Options are developed in response to specific fire management direction established for the Forest Plan. The objective is to identify the most cost-efficient option meeting resource protection and management objectives.

FLOOD PLAINS - Lowland and relatively flat areas adjoining inland and coastal water including, as a minimum, that area subject to one percent or greater chance of flooding in any given year

FORAGE - All browse and non woody plants available to livestock or wildlife for grazing or harvestable for feed.

FORB - Any herb other than grass.

FORDRY - That forested ecotype where the climax conifer species is Douglas-fir or ponderosa pine.

FOREGROUND - A term used in visual (scenery) management to describe the stand of trees immediately adjacent to a high-value scenic area, recreation facility, or forest highway (see “Background”, “Middleground”).

FOREST LAND - Land at least 10 percent occupied by forest trees of any size or formerly having had such cover and not currently developed for non-forest use. Lands developed for non-forest use include areas devoted to crops, improved pasture, residential or administrative areas, improved roads of any width and adjoining road clearing and powerline clearing of any width (36 CFR 219.3)

FOREST AND RANGELAND RENEWABLE RESOURCES PLANNING ACT (RPA) 1974 - An act of Congress requiring the preparation of a program for the management of the National Forest’s renewable resources and preparation of land and resource management plans for units of the National Forest System. It also requires a continuing inventory of all National Forest System lands and renewable resources.

FOREST-WIDE STANDARD - A principle requiring a specific level of attainment; a rule to measure against. The Forest-wide Standards apply to all areas of the Forest regardless of the other prescriptions applied.

FORPLAN - A linear programming system used for developing and analyzing Forest Planning Alternatives.

FORWET - That forested ecotype where conifer trees other than Douglas-fir or ponderosa pine are climax species over time. Characterized by more available moisture than the forested dry (FORDRY) zone.

FREE-TO-GROW - A term used by silviculturists to indicate that trees are free of growth restraints, the most common of which is competing overtopping vegetation.

FUELBREAK - Any natural or constructed barrier utilized to segregate, stop, or control the spread of fire

FUELS - Any material that will carry and sustain a forest fire, primarily natural materials, both live and dead.

FUEL TREATMENT - The rearrangement or disposal of natural or activity fuels to reduce the fire hazard

G

GAME - Wildlife that are hunted for sport and regulated by State Game regulations.

GENERAL DISTRIBUTION - The geographic area presently occupied, often on a seasonal basis, by a species within the planning area. Distribution is not to be confused with present occupancy of specific habitat(s). Resource management activities will create changes in habitat which will force local shifts in occupancy.

GENERAL FOREST (GF) - The portion of the Forest where timber management and other consumptive uses are emphasized.

GENETIC INTEGRITY - Refers to a normal healthy genetic pool (foundation) within a biological population to provide for long-term maintenance and survival of the species. Of specific concern in management direction is the prevention of loss of genetic variance (heterozygosity) and the avoidance of inbreeding depression, an important part of a given population's genetic integrity within the gene pool.

GOAL - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad general terms and is timeless in that it has no specific date by which it is to be completed. Goal statements form the principle basis from which objectives are developed. (36 CFR 219.3)

GOODS AND SERVICES - The various outputs, including on-site uses, produced from forest and rangeland resources. (36 CFR 219.3)

GRADIENT - Change of elevation, velocity, pressure or other characteristics per unit length of slope.

GROUP SELECTION CUTTING - Removal of tree groups ranging in size from a fraction of an acre up to about 2 acres in area that is smaller than the minimum feasible for even-aged management of a single stand.

GUIDELINE - An indication or outline of policy or conduct; i.e. any issuance that assists in determining the course of direction to be taken in any planned action to accomplish a specific objective.

GULLY - A channel or miniature valley cut by concentrated runoff but through which water commonly flows only during and immediately after heavy rains or during the melting of snow.

GULLY EROSION - The erosion process whereby water accumulates in narrow channels and, over short periods, removes the soil from this narrow area to considerable depths, ranging from one to two feet to as much as 75 to 100 feet.

H

HABITAT - The place where a plant or animal naturally or normally lives and grows.

HABITAT CAPABILITY - The estimated ability of an area, given existing or predicted habitat conditions, to support a wildlife, fish or plant population. It is measured in terms of potential population numbers.

HARVEST CUTTING METHOD - A combination of interrelated actions whereby forests are tended, harvested, and replaced. The combination of management practices used to manipulate the vegetation in forests. Harvest cutting methods are classified as even-aged and uneven-aged.

HEAVING - The partial lifting of plants out of the ground, frequently breaking their roots, as a result of freezing and thawing of the surface soil during the winter.

HIDING COVER - Vegetation capable of hiding 90 percent of a standing deer or elk from the view of a human at a distance of 200 feet.

HIGH QUALITY HABITAT - Habitat which completely satisfies a species existence requirement

HORIZONTAL DIVERSITY - The distribution and abundance of plant and animal communities or successional stages across an area of land; the greater the number of communities, the higher the degree of horizontal diversity. This concept is close to, but not exactly the same as, "even-aged management," although each may influence the other. Application of even-aged management, for example, can be designed to accomplish horizontal diversity objectives.

HUMAN RESOURCE PROGRAMS - Providing human and natural resource benefits through administering and hosting programs in work, training, and education for the unemployed, the underemployed, the elderly, the young and others with special needs.

HYDRAULIC GRADIENT - The slope of the hydraulic grade line. The slope of the free surface of water flowing in an open channel

INDICATOR SPECIES - A wildlife management scheme in which the welfare of a selected species is presumed to indicate the welfare of other species. The condition of the selected species can be used to assess the impacts of management actions on a particular area.

INITIAL ACTION - The prompt, preplanned response to a wildfire.

INTEGRATED PEST MANAGEMENT - A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are studied and weighed. The information considered in selecting appropriate strategies includes the impact of the unregulated pest population on various resources values, alternative regulatory tactics and strategies, and benefit/cost estimates for these alternative strategies. Regulatory strategies are based on sound silvicultural practices and ecology of the pest-host system and consist of a combination of tactics such as timber stand improvement plus selective use of pesticides. A basic principle in the choice of strategy is that it be ecologically compatible or acceptable (36 CFR 219.3)

INTEGRATED RESOURCE MANAGEMENT - A management strategy which emphasizes no resource element to the exclusion or violation of the minimum legal standards of others.

INTENSIVE FOREST MANAGEMENT - A high investment level of timber management that includes regeneration with genetically improved seedling stock, control of competing vegetation, fill-in planting, precommercial thinning as needed for stocking control, and one or more commercial thinnings.

INTERDISCIPLINARY TEAM (ID TEAM) - A team of people that collectively represent several disciplines and whose duty it is to coordinate and integrate the planning activities

INTERMITTENT STREAM - A stream that runs water in most months, but does not run water during dry seasons of most years.

INVENTORIED ROADLESS AREA - Areas of undeveloped Federal land, greater than 5,000 acres in size, within which there are no improved roads maintained for travel by means of motorized vehicles intended for highway use. Exceptions are those areas less than 5,000 acres manageable in their natural condition, contiguous to existing wilderness, or are of issue to the public.

IRRETRIEVABLE - Applies to losses of production, harvest, or use of renewable natural resources. For example, some or all of the timber production from an area is irretrievably lost during the time an area is used as a winter sports site. If the use is changed, timber production can be resumed. The production lost is irretrievable, but the action is not irreversible.

IRREVERSIBLE - Applies primarily to the use of nonrenewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long time periods. Irreversible also includes loss of future options.

ISSUE - A point, matter, or question of public discussion or interest to be addressed or decided through the planning process.

K

KNUTSON-VANDENBERG ACT (KV) - Legislation authorizing the collection of money from timber sale receipts for reforestation, stand improvements, and other resource improvement or mitigation projects on timber sale areas.

KV - An abbreviation of Knutson-Vandenberg.

L

LAND ALLOCATION - The assignment of a management emphasis to particular land areas with the purpose of achieving the goals and objectives of that alternative.

LANDINGS - Those designated areas within a timber sale where logs are temporarily stored before transport to a mill.

LANDTYPE - A portion of the landscape resulting from geomorphic and climatic processes with defined characteristics having predictable soil, hydrologic, engineering productivity, and other behavior.

LEASABLE MINERALS - Coal, oil, gas, phosphate, sodium, potassium, oil shale, sulphur, geothermal steam
Also includes other minerals on acquired National Forest lands

LIMITING HABITAT - Habitat which restricts the distribution, numbers, or condition of an organism

LOCATABLE MINERALS - Generally includes those hardrock minerals which are mined and processed for the recovery of metals, but may also include certain non-metallic minerals and uncommon varieties of mineral materials.

LONG-TERM SUSTAINED YIELD TIMBER CAPACITY - The highest uniform wood yield from lands being managed for timber production that may be sustained under a specified management intensity consistent with multiple-use objectives. (36 CFR 219.3)

M

M - Thousand

MANAGEMENT AREA - An area with similar management objectives and a common management prescription

MANAGEMENT CONCERN - An issue, problem, or a condition which constrains the range of management practices identified by the Forest Service in the planning process. (36 CFR 219.3)

MANAGEMENT DIRECTION - A statement of multiple-use and other goals and objectives, the associated management prescriptions, and standards and guidelines for attaining them (36 CFR 219.3)

MANAGEMENT INTENSITY - The management practice or combination of management practices and associated costs designed to obtain different levels of goods and services. (36 CFR 219.3)

MANAGEMENT PRACTICE - A specific activity, measure, course of action, or treatment. (36 CFR 219.3)

MANAGEMENT PRESCRIPTION - Management practices and intensity of management selected and scheduled for application on a specific area to attain multiple-use and other goals and objectives. (36 CFR 219.3)

MANAGEMENT REQUIREMENT (MR) - Minimum standards for resource protection, vegetation manipulation, silvicultural practices, even-aged management, riparian areas, and soil and water resources, to be met in accomplishing National Forest System goals and objectives.

MARGINAL TIMBER COMPONENT - Timber on which the income just equals or could just equal the costs of production under a given form of management.

MARKET RESOURCES - Products derived from renewable and nonrenewable resources that have a well-established market value; for example, forage, timber, water, and minerals.

MARKET VALUE - The unit price of an output normally exchanged in a market after at least one stage of production, expressed in terms of what people are willing to pay

MASS MOVEMENT - A general term for any of the variety of processes by which large masses of earth material are moved down slope by gravitational forces, either slowly or quickly.

MATURE TIMBER - Trees that have attained full development, particularly in height, and are in full seed production.

MAXIMUM MODIFICATION - A visual quality objective meaning man's activity may dominate the characteristic landscape but should appear as a natural occurrence when viewed as background.

MBF - Thousand board feet. A measure of wood volume

MCF - Thousand cubic feet. A measure of wood volume. The conversion ratio for the Wenatchee National Forest is 5.45 board feet per one cubic foot of wood

MEAN ANNUAL INCREMENT OF GROWTH - The total increase in girth, diameter, basal area, height, or volume of individual trees or a stand up to a given age, divided by that age.

MIDDLEGROUND - A term used in visual management to describe the visible terrain beyond the foreground where individual trees are still visible but do not stand out distinctly from the stand

MINERAL SOIL - Weathered rock materials usually containing less than 20 percent organic matter.

MINERAL WITHDRAWAL - The exclusion of locatable mineral deposits from mineral entry on areas required for administrative sites by the Forest Service and other areas highly valued by the public. Public lands withdrawn from entry under the General Mining Laws and/or the Mineral Leasing Laws.

MINIMUM VIABLE POPULATION - The low end of the viable population range

MINING CLAIMS - That portion of the public estate held by law for mining purposes in which the right of exclusive possession of locatable mineral deposits is vested to the locator of a deposit.

MITIGATION - Actions to avoid, minimize, reduce, eliminate, or rectify the impact of a management practice

MM - Million.

MMBF - Million board feet.

MMCF - Million cubic feet.

MONITORING - The periodic evaluation of Forest Plan management practices on a sample basis to determine how well objectives have been met.

MODIFICATION - A visual quality objective meaning man's activity may dominate the characteristic landscape but must, at the same time, utilize natural established form, line, color, and texture. It should appear as a natural occurrence when viewed in foreground or middleground.

MULTIPLE USE - The management of all the various renewable surface resources of the National Forests so that they are utilized in the combination that will best meet the needs of the American people. The concept also includes making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in the use to conform to changing needs and conditions. Some lands will be used for less than all of the resources. There will be harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land. Consideration will be given to the relative values of the various resources, and management will not necessarily favor the combination of uses that will give the greatest dollar return or the greatest unit output.

MUNICIPAL SUPPLY WATERSHED - A watershed that provides water for human consumption where Forest Service management could have a significant effect upon the quality of water at the point of intake. The watershed must provide water utilized by a community or any other public water system regularly serving 25 individuals at least 60 days out of the year or provide at least 15 service connections. This definition can include such facilities as campgrounds, organization camps, resorts, residential areas, etc.

NAAQS - National Ambient Air Quality Standards

NATIONAL ENVIRONMENTAL POLICY ACT OF 1969 (NEPA) - An Act, to declare a National policy which will encourage productive and enjoyable harmony between man and his environment; to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man, to enrich the understanding of the ecological systems and natural resources important to the nation; and to establish a Council on Environmental Quality.

NATIONAL FOREST MANAGEMENT ACT OF 1976 (NFMA) - An Act amending the Forest and Rangeland Renewable Resources Planning Act. NFMA requires the preparation of Regional and Forest Plans and the preparation of regulations to guide that development.

NATIONAL FOREST SYSTEMS - All National Forest lands reserved or withdrawn from the public domain of the United States, all National Forest lands acquired through purchase, exchange, donation, or other means, the National Grasslands and land utilization projects administered under Title III of the Bankhead-Jones Farm Tenant Act (50 Stat. 525, 7 U.S.C. 1010-1012), and other lands, waters or interests therein which are administered by the Forest Service or are designated for administration through the Forest Service as a part of the system (16 U.S.C. 1608)

NATURAL FOREST - The condition of a forest environment at any point in time including its associated plant and animal communities, which has been reached essentially through the process of natural succession. This process would include the effects of natural catastrophic occurrences.

NDF - An abbreviation of Non-Declining Flow.

NEPA - An abbreviation of National Environmental Policy Act.

NET PUBLIC BENEFITS - An expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index. The maximization of net public benefits to be derived from management of the units of the National Forest System is consistent with the principles of multiple-use and sustained-yield. (36 CFR 219.3)

NET VALUE CHANGE - The estimation process carried out by an interdisciplinary team to assess positive and negative effects of individual resource allocation or management area designation. An estimation of physical effects and economic consequences of various fire intensity levels.

NFMA - An abbreviation of the National Forest Management Act of 1976.

NON-CHARGEABLE TIMBER HARVEST - Timber harvest that is not chargeable to the allowable sale quantity.

NON-CONSUMPTIVE USE - That use of a resource that does not reduce the supply

NON-DECLINING FLOW (NDF) - A level of timber production assigned so that the planned timber sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade.

NON-GAME - Any species of wildlife or fish which is not managed or otherwise controlled by hunting, fishing, or trapping regulations.

NON-MARKET - Products derived from National Forest resources that do not have a well-established market value, for example, recreation, wilderness, wildlife.

NON-POINT SOURCE POLLUTION - Pollution whose source is general rather than specific in location.

NON-PRICED OUTPUTS - Outputs for which there is no available market transaction evidence and no reasonable basis for estimating a dollar value. Subjective non-dollar values are given to non-priced outputs.

NOXIOUS WEEDS - A plant considered to be extremely destructive or harmful to agriculture and designated by law. An undesirable species that conflicts with, restricts, or otherwise causes problems with the management objectives.

NPB - An abbreviation of net public benefits.

OBJECTIVE - A concise, time-specific statement of measurable planned results that respond to pre-established goals. An objective forms the basis for further planning to define the precise steps to be taken and the resources to be used in achieving identified goals. (36 CFR 219.3)

OCCUPANCY TRESPASS - The illegal occupation or possession of National Forest land or property

OFF-ROAD VEHICLE (ORV) - Any motorized vehicle designed for or capable of cross-country travel on or immediately over land, water, snow, ice, or other natural terrain.

OLD GROWTH STAND - An old-growth stand is defined as any stand of trees 10 acres or greater generally containing the following characteristics: 1) stands contain mature and overmature trees in the overstory and are well into the mature growth stage; 2) stands will usually contain a multilayered canopy and trees of several age classes, 3) standing dead trees and down material are present; and 4) evidence of man's activities may be present but does not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand

OLIGOTROPHIC - Lakes having low nutrient supplies which are poor producers of organic matter.

OPPORTUNITY COSTS - The values of a resource's foregone net benefits in its most economically efficient alternative use.

OPTIMUM DENSITY - For wildlife, the maximum rate of animal stocking possible without inducing damage to vegetation or related resources, may vary from year to year because of environmental and/or population factors.

ORV - An abbreviation for off-road vehicles.

OUTPUT - A good, service, or on-site use that is produced from forest and rangeland resources. See FSH 1309.11 for forest and rangeland outputs, codes and units of measure. Examples: X06 - Softwood Sawtimber production - MCF; X80 - Increased Water Yield - Acre feet; W01 - Primitive Recreation Use - RVD's

OVERSTORY - That portion of the trees in a forest of more than one story, forming the upper or uppermost canopy layer.

PAOT - Persons At One Time - Public recreational measurement term. The number of people in an area or using a facility at one time

PARENT MATERIAL - The unconsolidated and more or less chemically weathered mineral or organic matter from which the upper horizons of the soil profile are developed

PARTIAL CUT - Covers a variety of silvicultural practices where a portion of the stand is removed and a portion is left.

PARTIAL RETENTION - A visual quality objective where man's activities may be evident but subordinate to the characteristic landscape.

PARTICULATES - Small particles suspended in the air and generally considered pollutants

PATENTED MINING CLAIMS - A patent is a document which conveys a title. Public law provides that when patented, a mining claim becomes private property and is land over which the United States has no property rights, except as may be reserved in the patent. After a mining claim is patented, the owner does not have to comply with requirements of the General Federal Mining law, but is required to meet State regulations

PAYMENT IN LIEU OF TAXES - Payments to local or State governments based on ownership of Federal land and not directly dependent on production of outputs or receipt sharing. Specifically, they include payments made under the Payments in Lieu of Taxes Act of 1976 by U S Department of the Interior.

PERENNIAL STREAMS - A stream that runs water year around.

PERSONS-AT-ONE-TIME (PAOT) - A recreation capacity measurement term indicating the number of people that can use a facility or area at one time.

PLANNING AREA - The area of the National Forest System covered by a regional guide or Forest Plan (36 CFR 219.3)

PLANNING HORIZON - The overall time period considered in the planning process that spans all activities covered in the analysis or plan and all future conditions and effects of proposed actions which would influence the planning decisions. (36 CFR 219.3)

PLANNING PERIOD - One decade The time interval within the planning horizon that is used to show incremental changes in yields, costs, effects, and benefits. (36 CFR 219 3)

PLANT COMMUNITIES - A vegetation complex unique in its combination of plants which occur in particular locations under particular influences. A plant community is a reflection of integrated environmental influences on the site - such as soils, temperature, elevation, solar radiation, slope, aspect, and rainfall.

PNV - An abbreviation of present net value.

POTENTIAL YIELD - (This term is in reference to the Timber Management plans only.) Optimum sustained yield of timber harvest volume attainable with intensive forestry on available commercial forest land (forest lands able to produce 20 cubic feet of timber per acre per year or more) while considering the interrelationship with other forest resources and uses. Programmable net salvage volume and volume from marginally economical lands are also included.

PRACTICES - Those management activities that are proposed or expected to occur.

PRECOMMERCIAL THINNING - The selective felling or removal of trees in a young stand, primarily to accelerate diameter increment on the remaining stems, maintain a specific stocking or stand density range, and improve the vigor and quality of the trees that remain.

PRESCRIBED FIRE - A wildland fire burning under preplanned specified conditions which will accomplish certain planned objectives. The fire may result from either planned or unplanned ignitions.

PRESCRIBED NATURAL FIRE - The use of unplanned natural ignitions to meet management prescriptions.

PRESENT NET VALUE (PNV) - The difference between the discounted values (benefits) of all outputs to which monetary values or established market prices are assigned, and the total discounted costs of managing the planning area (36 CFR 219.3)

PRESERVATION - A visual quality objective that allows only ecological changes to take place.

PRESUPPRESSION - Activities required in advance of fire occurrence to ensure an effective suppression action. It includes (1) recruiting and training fire forces, (2) planning and organizing attack methods, (3) procuring and maintaining fire equipment, and (4) maintaining structural improvements necessary for the fire program.

PRICE - The unit value of an output expressed in dollars.

PRIMARY CAVITY EXCAVATOR - Wildlife species that digs or chips out cavities in wood to provide itself or its mate with a site for nesting or roosting.

PRIMITIVE RECREATION - Those recreation activities which occur in areas characterized by an essentially unmodified natural environment of fairly large size (2,500 acres or greater).

PRODUCTION POTENTIAL - The capability of the land or water to produce a given resource

PRODUCTIVE FOREST LANDS - Forest lands that are capable of producing crops of industrial wood and have not been reserved or deferred from timber management.

PROGRAM DEVELOPMENT AND BUDGETING - The process by which forest management activities are proposed and funded

PROGRAM ELEMENT - An individual Forest Service area of responsibility, which in combination with other elements, comprises the statutory or Executive directed mission of the Forest Service. Specific Forest Service program elements are defined in the Management Information Handbook (FSH 1309 11)

PROGRAMMED HARVEST - The amount of timber that is scheduled for harvesting. Includes salvage and cull timber volumes. It is based on current demand, funding, and multiple use considerations.

PUBLIC ACCESS - Usually refers to a road or trail route over which a public agency claims a right-of-way for public use

PUBLIC ISSUE - A subject or question of widespread public interest relating to management of the National Forest System. (36 CFR 219.3)

PURCHASER CREDIT - Credit earned by the purchaser of a National Forest timber sale in return for construction of contract-specified roads. Earned purchaser credit may be used by the purchaser as payment for National Forest timber removed.

RANGE ALLOTMENT - A designated area containing land suitable and available for livestock grazing use upon which a specified number and kind of livestock are grazed under an approved allotment management plan. It is the basic management unit of the range resource on National Forest System lands administered by the Forest Service.

RANGER DISTRICT - An administrative subdivision of the Forest, supervised by a District Ranger who reports to the Forest Supervisor.

RAPTORS - Any predatory bird - such as a falcon, hawk, eagle or owl - that has feet with sharp talons or claws adapted for seizing prey and a hooked beak for tearing flesh.

RARE II - An abbreviation of Roadless Area Review and Evaluation II

REAL DOLLAR VALUE - A monetary value that compensates for the effects of inflation. (36 CFR 219.3)

RECORD OF DECISION (ROD) - A document separate from but associated with an Environmental Impact Statement which states the decision, identifies all alternatives, specifying which were environmentally preferable, and states whether all practicable means to avoid environmental harm from the alternative have been adopted, and if not, why not. (40 CFR 1505.2)

RECREATION CAPACITY - The number of people that can take advantage of recreation opportunity at any one time without substantially diminishing the quality of the experience or the biophysical resources.

RECREATION INFORMATION MANAGEMENT (RIM) - The Forest Service system for recording recreation facility condition and use.

RECREATION OPPORTUNITY - An opportunity for a user to participate in a preferred activity within a preferred setting, in order to realize those satisfying experiences which are desired

RECREATION OPPORTUNITY SPECTRUM (ROS) - Land delineations that identify a variety of recreation experience opportunities categorized into six classes on a continuum from primitive to urban. Each class is defined in terms of the degree to which it satisfies certain recreation experience needs. This is measured based on the extent to which the natural environment has been modified, the type of facilities provided, the degree of outdoor skills needed to enjoy the area, and the relative density of recreation use. The seven classes are.

1. **Primitive**--Area is characterized by an essentially unmodified natural environment of fairly large size. Interaction between users is very low, and evidence of other users is minimal. The area is managed to be essentially free from evidence of management restrictions and controls. Motorized use within the area is not permitted.

2. **Semi-primitive Non-motorized**--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Interaction between users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but subtle. Motorized recreation use is not permitted, but local roads used for other resource management activities may be present on a limited basis. Use of such roads is restricted to minimize impacts on recreational experience opportunities.

3. Semi-primitive Motorized--Area is characterized by a predominantly natural or natural-appearing environment of moderate to large size. Concentration of users is low, but there is often evidence of other users. The area is managed in such a way that minimum onsite controls and restrictions may be present, but subtle Motorized recreation use of local primitive or collector roads with predominantly natural surfaces and trails suitable for motor bikes is permitted.

4. Roaded Natural--Area is characterized by predominantly natural-appearing environments with moderate evidence of the sights and sounds of man. Such evidence usually harmonizes with the natural environment. Interaction between users may be moderate to high, and evidence of other users prevalent. Resource modification and utilization practices are evident but harmonize with the natural environment. Conventional motorized use is allowed and incorporated into construction standards and design of facilities.

5. Roaded Modified--Area is generally natural appearing, but has significant vegetation management and resource modification. Modifications generally harmonize with the natural environment. A moderate opportunity exists for isolation and undisturbed activities but some interaction with other visitors can be expected. Conventional motorized use is allowed and incorporated into construction standards and designs of facilities.

6. Rural--Area is characterized by a natural environment that has been substantially modified by development of structures, vegetative manipulation, or pastoral agricultural development. Resource modification and utilization practices may be used to enhance specific recreation activities and to maintain vegetative cover and soil. Sights and sounds of humans are readily evident, and the interaction between users is often moderate to high. A considerable number of facilities are designed for use by a large number of people. Facilities are often provided for special activities. Moderate user densities are present away from developed sites. Facilities for intensified motorized use and parking are available.

7. Urban--Area is characterized by a substantially urbanized environment, although the background may have natural-appearing elements. Renewable resource modification and utilization practices are often used to enhance specific recreation activities. Vegetative cover is often exotic and manicured. Sights and sounds of humans are predominant on site and in nearby areas. Facilities for highly intensified motor use and parking are available with forms of mass transit often available to carry people throughout the site.

RECREATION VISITOR DAY (RVD) - A unit for measuring recreation use, with 12 visitor hours in a visitor day. This may consist of one person for 12 hours, 12 persons for one hour, or any equivalent combination of continuous or intermittent recreation use by individuals or groups.

REFORESTATION - The natural or artificial restocking of an area with forest trees; most commonly used in reference to artificial restocking.

REGENERATION - The actual seedlings and saplings existing in a stand; or the act of establishing young trees naturally or artificially.

REGENERATION CUT - Any removal of trees to make regeneration possible.

REGION - An area covered by a Regional guide. See FSM 1221.3 for organizational definitions.

REGIONAL FORESTER - The official responsible for administering a single Forest Service region.

REGIONAL GUIDE - The guide developed to meet the requirements of the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended. It guides all natural resource management activities, and establishes management standards and guidelines for the National Forest System lands within a given region, it also disaggregates the assigned Regional RPA objectives to the Forests within that Region.

REGULATED VOLUME - Same as Allowable Sale Quantity.

REHABILITATION - A short-term management alternative used to return existing visual impacts in the natural landscape to a desired visual quality.

RELEASE - Freeing a tree or group of trees from competition by cutting or otherwise eliminating vegetation that is overtopping or closely surrounding them.

REMOVAL CUT (Final Cut) - The removal of the last seed bearing or shelter trees after regeneration is established under a shelterwood method.

RESEARCH NATURAL AREA - An area of land in as near a natural condition as possible that exemplifies typical or unique vegetation and associated biotic, soil, geologic, and aquatic features. The area is set aside to preserve a representative sample of an ecological community primarily for non-manipulative scientific and education purposes.

RESERVED FOREST LAND - Public forest land withdrawn from timber utilization through statute or administrative regulations (e.g. Wilderness, Research Natural Areas).

RESIDENT FISH - Generally refers to trout and char which are not anadromous. However, some Forest reservoirs contain warmwater resident fish species such as bass.

RESIDUAL STAND - The trees remaining standing after some form of selection cutting is performed on a stand

RESIDUE - Material which includes both desired and unwanted vegetative residues which result from an activity or natural event.

RESOURCE PLANNING ACT (RPA) - The Forest and Rangeland Renewable Resources Planning Act of 1974 Also refers to the National Assessment and Recommended Program developed to fulfill the requirements of the Act.

RESPONSIBLE LINE OFFICER - For land management planning purposes, the Forest Service employee who has been delegated the authority to carry out a specific planning action. (36 CFR 219.3)

REST-ROTATION - A system of grazing management which defines systematically recurring periods of grazing and deferment for two or more pastures or management units.

RETENTION - A visual quality objective where human activities are not evident to the casual forest visitor.

RILL EROSION - An erosion process in which numerous small channels only several inches deep are formed, occurs mainly on recently cultivated or disturbed soils.

RIPARIAN - Pertaining to acres of land directly influenced by water. Riparian areas usually have visible vegetative or physical characteristics reflecting this water influence. Stream sides, lake borders, or marshes are typical riparian areas.

RIPARIAN-AQUATIC PROTECTION ZONE - A geographically delineated area with distinctive resource values and characteristics that is comprised of aquatic and riparian ecosystems. This includes floodplains, wetlands, and all areas within a variable horizontal distance from the normal line of high water of a stream channel or from the shoreline of a standing body of water

RISK - The degree and probability of loss based on chance.

RUNOFF - That part of the water which travels over the soil surface to the nearest outlet or channel

RNA - An abbreviation of Research Natural Area.

ROAD - A general term denoting a way for purposes of travel by vehicles greater than 40 inches in width

a. **Forest Arterial Road**. Provides services to large land areas and usually connects with public highways or other Forest arterial roads to form an integrated network of primary travel routes. The location and standard are often determined by a demand for maximum mobility and travel efficiency rather than specific resource management service. It is usually developed and operated for long-term land and resource management purposes and constant service (FSM 7710.51).

b. **Forest Collector Road**. Serves smaller land areas than a Forest arterial road and is usually connected to a Forest arterial or public highway. Collects traffic from Forest local roads and/or terminal facilities. The location and standard are influenced by both long-term multiresource service needs as well as travel efficiency. May be operated for either constant or intermittent service, depending on land use and resource management objectives for the area served by the facility (FSM 7710.51).

c. **Forest Local Road**. Connects terminal facilities with Forest collector or Forest arterial roads or public highways. The location and standard are usually controlled by specific resource activity requirements rather than travel efficiency needs (FSM 7710.51).

ROADLESS AREA - See Inventoried Roadless Area.

ROADLESS AREA REVIEW AND EVALUATION II (RARE II) - The national inventory of roadless and undeveloped areas within the National Forest and grasslands. This refers to the second such assessment, which was documented in the Final Environmental Impact Statement of the Roadless Area Review and Evaluation, January 1979.

ROS - An abbreviation of Recreation Opportunity Spectrum.

ROTATION - Planned number of years, between the formation of a generation of trees and its final harvest of a specified stage of maturity.

ROTATION AGE - The age of a stand when harvested.

ROUNDWOOD - Commercially valuable wood that is generally too small to be made into boards.

RPA - The Forest and Rangeland Renewable Resources Planning Act of 1974 Also refers to the National Assessment and Recommended Program developed to fill the requirements of the Act.

RPA RESOURCE TARGETS - Quantified resource goals stated in the Forest Service Region 6 plan.

RVD's An abbreviation of Recreation Visitor Days.

SALE SCHEDULE - The quantity of timber planned for sale by time period from an area of suitable land covered by a forest plan. The first period (usually a decade) of the selected sale schedule provides the allowable sale quantity. Future periods are shown to ensure that long term sustained yield will be achieved and maintained. (36 CFR 219.3)

SALVAGE CUTTING - Intermediate cuttings made to remove trees that are dead or in imminent danger of being killed by injurious agents

SANITATION CUTTING - The removal of dead, damaged or susceptible trees primarily to prevent the spread of insect pests or diseases.

SATURATION DENSITY - (Same as tolerance density.) This term relates to the requirement of many wildlife species for living space. This condition is most marked in territorial species. Space is the limiting factor to the further increases of the population density of these species

SCENIC AREAS - Places of outstanding or matchless beauty which require special management to preserve these qualities. They may be established under 36 CFR 294.1 whenever lands possessing outstanding or unique natural beauty warrant this classification.

SCENIC RIVERS - See Wild and Scenic Rivers

SCHEDULED TIMBER HARVEST - Timber harvest that is chargeable to the annual allowable sale quantity for the Forest.

SCOPING PROCESS - A part of the National Environmental Policy Act (NEPA) process; early and open activities used to determine the scope and significance of the issues; and the range of actions, alternatives, and impacts to be considered in an Environmental Impact Statement (40 CFR 1501.7).

SCORP - Statewide Comprehensive Outdoor Recreation Plan.

SECOND GROWTH - Forest growth that has become established following some interference with the previous forest growth (e.g., cutting, serious fire, or insect attack).

SECONDARY USER SPECIES - Wildlife that occupies a site (cavity in a snag or a den) created by another species.

SEDIMENT - Solid material, both mineral and organic, that is in suspension, and is being transported from its site of origin by air, water, gravity, or ice, or has come to rest on the earth's surface either above or below sea level.

SEDIMENT YIELD - the total sediment outflow from a drainage basin in a specified period of time.

SEED TREE CUTTING - Removing all mature trees from a stand except for selected seed-bearing trees retained on site to provide a seed source for stand regeneration.

SELECTION CUT - Selection cutting is the periodic removal of mature trees individually or in small groups from an uneven-aged forest. By this method, both regeneration cutting and tending of immature stand components are accomplished at each entry.

SEMI-PRIMITIVE MOTORIZED ROS CLASS - See RECREATION OPPORTUNITY SPECTRUM

SEMI-PRIMITIVE NON-MOTORIZED ROS CLASS - See RECREATION OPPORTUNITY SPECTRUM

SENSITIVE SPECIES - Those species of plants or animals that have appeared in the Federal Register as proposed for classification and are under consideration for official listing as endangered or threatened species, that are on an official State list, or that are recognized by the Regional Forester as needing special management to prevent their being placed on Federal or State lists.

SERAL - A biotic community which is a developmental, transitory stage in an ecological succession.

SERAL STAGE--See "successional stage"

SHELTERWOOD CUTTING - Any regeneration cutting in a stand designed to establish a new stand under the protection (overhead or side) of the old stand. Usually the shelterwood involves two separate harvest operations. The first harvest (seed cut) is designed to create space and seed production to establish new trees. The second cut (removal cut) is designed to remove the remainder of the old stand before it begins to compete with the new stand for light and nutrients. This is usually within 10 years. (See also EXTENDED SHELTERWOOD.)

SHEET EROSION - The removal of a fairly uniform layer of soil from the land surface by runoff water.

SILVICULTURAL SYSTEM - A management process whereby forests are tended, harvested, and replaced resulting in a forest of distinctive form. Systems are classified according to the logging method that removes the mature crop and provides for regeneration and according to the type of forest thereby produced (36 CFR 219.3)

SILVICULTURE - The art and science of controlling the establishment, composition and growth of forests

SITE INDEX - A numerical evaluation of the quality of land for plant productivity which uses height growth as a function of age.

SITE PRODUCTIVITY - Production capability of specific areas of land to produce defined outputs such as AUMs, cubic feet/acre/yr., etc.

SIZE CLASS - For purposes of Forest planning, size class refers to the three intervals of tree stem diameter used for classification of timber in the Forest Plan data base:

less than five-inch diameter = seedling/sapling

five to eight-inch diameter = pole timber

greater than eight-inch diameter = sawtimber

SLASH - The wood residue left on the ground after timber cutting and/or accumulating there as a result of storm, fire, or other damage. It includes unused logs, uprooted stumps, broken or uprooted stems, branches, twigs, leaves, bark, and chips.

SMALL GAME - Birds and small mammals typically hunted or trapped.

SMOLT HABITAT CAPABILITY - Smolt habitat capability is a measure of the productive capability of aquatic habitat to produce smolts of a given species.

SNAG - A standing dead tree.

SOCIOECONOMIC - Pertaining to, or signifying the combination or interaction of, social and economic factors.

SOHA - An abbreviation for Spotted Owl Habitat Area

SOIL - The unconsolidated mineral and organic material on the immediate surface of the earth.

SOIL and WATER CONSERVATION PRACTICES (SWCP) -- The set of practices which ensures that soil productivity is maintained, soil loss and water quality impacts are minimized, and water related beneficial are protected during implementation of a project. These practices include the following: (1) State recognized Best Management Practices, (2) Forest-wide standards and guidelines (3) Management Area standards and guidelines, and (4) practices identified at the area and project levels based on on-site specific evaluation.

SOIL DISTURBANCE - Soil disturbance is the mixing of duff material or other woody material into the surface horizon or horizons without significant movement of the soil from one spot to another.

SOIL RESOURCE COMMITMENT - Soil resource commitment is a conversion of a productive site to an essentially nonproductive site for a period of more than 50 years.

SOIL SURVEYS - Systematic examinations of soils in the field and in laboratories which are then interpreted according to their adaptability for various crops, grasses and trees.

SOUND WOOD - Timber that is free from defect, damage, or decay, i.e., in solid, whole, good condition

SPECIAL TIMBER COMPONENT - (obsolete term) That part of the planned timber harvest area and volume where timber production may require special harvest methods, production rates, or other requirements to benefit or mitigate resources other than timber.

SPECIES MANAGEMENT GUIDE - A guide for management of an indicator species in a particular area. The guide includes management direction, schedules for utilization, inventories, research, monitoring, and optimum cover/forage relationships for the long term.

SPECIES RICHNESS MANAGEMENT - A wildlife management strategy to maintain viable populations of all resident species.

SPOTTED OWL HABITAT AREA (SOHA) - A habitat area designated to support one pair of owls. A dedicated SOHA does not allow scheduled timber harvest on otherwise suitable timber lands.

SPRING BREAK-UP - Time of year when roads are damaged or "break up" due to melting frost and ice, generally from first of March to middle of April

STAND - Timber possessing uniformity as regards to type, age class, risk class, vigor, size class, and stocking class

STANDARD - A principle requiring a specific level of attainment, a rule to measure against.

STANDARD TIMBER COMPONENT - That part of the planned timber harvest area and volume of normal or "standard" sawlog production Used in Timber Management Plans.

STOCKING - The degree of occupancy of land by trees as measured by basal area or number of trees as compared to a stocking standard.

STORET - The acronym for a computerized water quality data base operated nationwide by the U.S. Environmental Protection Agency.

STRATEGIC MINERALS - Those minerals of which the U.S. imports 50 percent or more from foreign sources (based on 1978 U.S. Bureau of Mines figures).

STREAM CLASS - Classification of streams based on the present and foreseeable uses made of the water, and the potential effects of on-site changes on downstream uses. Four classes are defined

Class I - Perennial or intermittent streams that provide a source of water for domestic use; are used by large numbers of fish for spawning, rearing or migration; and/or are major tributaries to other Class I streams.

Class II - Perennial or intermittent streams that are used by moderate though significant numbers of fish for spawning, rearing or migration; and/or may be tributaries to Class I streams or other Class II streams.

Class III - All other perennial streams not meeting higher class criteria.

Class IV - All other intermittent streams not meeting higher class criteria.

STREAMSIDE MANAGEMENT UNIT (SMU) - An area of varying width adjacent to a stream where practices that might affect water quality, fish and other aquatic resources are modified to meet water quality goals, for each class of stream.

SUB-BASIN - Further subdivision of the Columbia Basin for the Wenatchee N F (Chelan, Entiat, Wenatchee and Yakima Sub-basins).

SUBWATERSHED - A part of a whole watershed As used in this Forest plan: the part of a WATERSHED that lies within the boundary of the Wenatchee National Forest.

SUBSTANTIVE COMMENT - A comment that provides factual information, professional opinion, or informal judgement germane to the action being proposed

SUCCESSIONAL STAGE - A stage or recognizable condition of a plant community that occurs during its development from bare ground to climax For example, coniferous forests in the Blue Mountains progress through six recognized stages grass-forb; shrub-seedling; pole-sapling, young; mature, old growth.

SUITABILITY - The appropriateness of applying certain resource management practices to a particular area of land, as determined by an analysis of the economic and environmental consequences and the alternative uses foregone. A unit of land may be suitable for a variety of individual or combined management practices. (36 CFR 219.3)

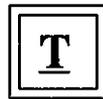

SUPPLY - The amount of an output that producers are willing to provide at a specific price, time period, and condition of sale.

SUPPRESSION - The action of extinguishing or confining a fire.

SURFACE RESOURCES - Renewable resources located on the earth's surface in contrast to ground water and mineral resources located below the earth's surface.

SURFACE RUNOFF - Water that flows over the ground surface and into streams and rivers.

SUSTAINED YIELD OF PRODUCTS AND SERVICES - The achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forest System without impairment of the productivity of the land. (36 CFR 219.3)

TARGETS - Output accomplishments assigned to the Forest by the Forest Service Regional Forester. A statement used to express planned results to be achieved within a stated period of time.

TEMPORARY ROAD --Any short-lived road not intended to be a part of the Forest development transportation system and not necessary for future resource management.

TENTATIVELY SUITABLE FOREST LAND - Forest land that is capable of producing crops of industrial wood and: (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soil productivity or watershed conditions, (c) existing technology and knowledge provides reasonable assurance that it is possible to restock adequately within five years after final harvest; and (d) adequate information is available to project responses to timber management activities.

THERMAL COVER - Cover used by animals to lessen the effects of weather; for elk, a stand of coniferous trees 12 meters (40 feet) or more tall with an average crown closure of 70 percent or more, for deer, cover may include saplings, shrubs, or trees at least 1.5 meters (5 feet tall) with 75 percent crown closure.

THREATENED SPECIES - Any species of animal or plant which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range and which has been designated in the Federal Register by the Secretary of Interior as a threatened species.

TIERING - The coverage of general matters in broader environmental impact statements with subsequent, narrower statements or environmental analyses incorporating by reference the general discussions and concentrating solely on specific issues.

TIMBER CLASSIFICATION - Forest land is classified under each of the land management alternatives according to how it relates to the management of the timber resource. The following are definitions of timber classifications used for this purpose.

1. **Nonforest**--Land that has never supported forests and land formerly forested where use for timber production is precluded by development or other uses.

2. **Forest**--Land at least 10-percent stocked (based on crown cover) by forest trees of any size, or formerly having had such tree cover and not currently developed for nonforest use.

3. Suitable--Commercial forest land identified as appropriate for timber production in the Forest planning process.

4 Unsuitable--Forest land withdrawn from timber utilization by statute or administrative regulation (for example, wilderness), or identified as not appropriate for timber production in the Forest planning process.

5. Commercial Forest--Forest land tentatively suitable for the production of continuous crops of timber and that has not been withdrawn from timber utilization.

TIMBER MANAGEMENT PLANS (TM PLANS) - Functional resource plans completed in 1963 for the Wenatchee Working Circle and 1969 for the Naches-Tieton Working Circle, which established a timber sale volume to be sold each year. They were not integrated resource plans which considered impacts to all other resources on the Forest.

TIMBER PRODUCTION - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees to be cut into logs, bolts, or other round sections for industrial or consumer use. For planning purposes, the term "timber production" does not include production of fuelwood (36 CFR 219.3)

TIMBER STAND IMPROVEMENT (TSI) - The elimination or suppression of the less desirable vegetation in favor of the more desirable tree growth. It includes thinning, cleaning, weeding, and release cuttings.

TOLERANT SPECIES - Plants that grow well in shade.

TOTAL SUSPENDED PARTICULATES (TSP) - Any finely divided material (solid or liquid) that is airborne with an aerodynamic diameter smaller than a few hundred micrometers.

TRANSITORY RANGE - Land that is suitable for grazing use of a nonenduring nature over a period of time. For example, on particular disturbed lands, grass may cover the area for a period of time before being replaced by trees or shrubs not suitable for forage.

TURBIDITY - The degree of opaqueness, or cloudiness, produced in water by suspended particulate matter, either organic or inorganic. Measured by light filtration or transmission and expressed in Nephelometric Turbidity Units (NTU).

UNCERTAINTY - Whenever a variety of outcomes are possible and a probability of any specific outcome cannot be assigned with any degree of accuracy.

UNDERSTORY - Vegetation growing under a higher canopy.

UNEVEN-AGED MANAGEMENT - The application of a combination of actions needed to simultaneously maintain continuous high forest cover, recurring regeneration of desirable species, and the orderly growth and development of trees through a range of diameter or age classes. This management must provide a sustained yield of forest products. Cutting is usually regulated by specifying the number or proportion of trees of particular sizes to retain within each area, thereby maintaining a planned distribution of size classes. Cutting methods that develop and maintain uneven-aged stands are single-tree selection and group selection. (36 CFR 219.3)

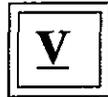

UNIFORM FLOW - A state of steady water flow where the mean velocity and cross sectional area are equal at all sections.

UNREGULATED TIMBER MANAGEMENT - Timber cut from those lands that are not organized to provide sustained yields of timber.

UNROADED ACRES - Those areas of undeveloped Federal land within which there are no improved roads maintained for travel by means of vehicles intended for highway use.

UTILIZATION STANDARDS - Standards guiding the use and removal of timber which is measured in terms of diameter at breast height (d.b.h.), top diameter inside the bark (top d.i.b.), and percent "soundness" of the wood.

UTILITY AND TRANSPORTATION CORRIDORS - A strip of land designated for the transportation of energy, commodities, and communications by railroad, state highway, electrical power transmission (69 KV and above), oil and gas and coal slurry pipelines 10 inches in diameter and larger, and tele-communication cable and electronic sites for interstate use. Transportation of minor amounts of power for short distances, such as short feeder lines from small power projects including geothermal or wind, or to serve customer subservice substations along the line, are not to be treated within the Forest Plan effort.

VARIETY CLASS - A classification system for establishing three visual landscape categories according to the relative importance of the visual features. Those with the most variety of diversity have the greatest potential for high scenic value. The three variety classes are distinctive, common and minimal.

VERTICAL DIVERSITY - The diversity in a stand that results from the complexity of the above ground structure of the vegetation; the more tiers of vegetation or the more diverse the species make up (or both), the higher the degree of vertical diversity. This concept is close to but not exactly the same as "uneven-aged management," although each may influence the other. Application of even-aged management, for example, can be designed to accomplish vertical diversity objectives.

VIABLE POPULATION - A population which has adequate numbers and dispersion of reproductive individuals to ensure the continued existence of the species population on the planning area.

VIEWSHED - The total landscape seen or potentially seen from all or a logical part of a travel route, use area, or water body.

VISITOR INFORMATION SERVICE (VIS) - Activities which interpret for visitors, in layman's language, Forest management, protection, utilization, and research. It also includes interpretation of local botany, geology, ecology, zoology, history, and archaeology.

VISUAL MANAGEMENT SYSTEM - The management system used to protect and enhance the visual resource.

VISUAL QUALITY OBJECTIVES (VQO's) - Categories of acceptable landscape alteration measured in degrees of deviation from the natural-appearing landscape. These categories include Preservation, Retention, Partial Retention, Modification, and Maximum Modification.

VISUAL RESOURCE (FOREST SCENERY) - The composite of basic terrain, geologic features, water features, vegetative patterns, and land-use effects that typify a land unit and influence the visual appeal the unit may have for visitors.

VQO - An abbreviation of visual quality objective.

WATER QUALITY - The biological, physical, and chemical properties of water that make it suitable for given specified uses. Different instream conditions of levels of water quality are needed to support different beneficial uses.

WATER YIELD - The measured output of the Forest's streams.

WATER YIELD INCREASE - Additional water released to Forest streams as a result of Forest management activities.

WATERSHED - The entire land area that contributes water to a drainage system or stream.

WETLANDS - Areas that are inundated by surface or ground water with a frequency sufficient to support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction. (Executive Order 11990.) Under normal circumstances the area does or would support a prevalence of vegetative or aquatic life.

WFUD'S - An abbreviation of Wildlife and Fish User Days.

WILD AND SCENIC RIVERS - Those rivers or sections of rivers designated as such by congressional action under the 1968 Wild and Scenic Rivers Act, as supplemented and amended, or those sections of rivers designated as wild, scenic, or recreational by an act of the Legislature of the State or States through which they flow. Wild and scenic rivers may be classified and administered under one or more of the following categories:

1. **Wild River Areas**--Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.
2. **Scenic River Areas**--Those rivers or sections of rivers that are free of impoundments, with watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.
3. **Recreational River Areas**--Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

WILDERNESS - Areas designated by congressional action under the 1964 Wilderness Act. Wilderness is defined as undeveloped Federal land retaining its primeval character and influence without permanent improvements or human habitation. Wilderness areas are protected and managed to preserve their natural conditions, which generally appear to have been affected primarily by the forces of nature, with the imprint of human activity substantially unnoticeable; have outstanding opportunities for solitude or for a primitive and unconfined type of recreation; include at least 5,000 acres or are of sufficient size to make practical their preservation, enjoyment, and use in an unimpaired condition; and may contain features of scientific, educational, scenic, or historical value as well as ecologic and geologic interest.

WILDERNESS RECREATION OPPORTUNITY SPECTRUM (WROS) --The Wilderness Recreation Opportunity Spectrum is an extension of the Recreation Opportunity Spectrum into Wilderness. There are four classes; Pristine, Primitive, Semi-Primitive and Transition. The Primitive and Semi-Primitive WROS classes correspond very closely to the Primitive and Semi-Primitive Non-Motorized classes in ROS. The Pristine WROS class is the most undisturbed, natural portion of a primitive area. The Transition WROS class is essentially a Semi-Primitive WROS class area with greater allowances for social and biological influences of humans.

WILDFIRE - Any wildland fire not designated and managed as a prescribed fire within an approved prescription.

WILDLIFE AND FISH USER DAY (WFUD) - One WFUD consists of 12 hours of recreation use that is the result of fish or wildlife.

WINTER RANGE - The area available to and used by big game through the winter season.

WITHDRAWAL - An order removing specific land areas from availability for certain uses.

WORKING CIRCLE - A geographic division of the Forest created for administrative or marketing purposes. The Wenatchee Working Circle in the Timber Management (TM) plans includes Chelan, Entiat, Lake Wenatchee, Leavenworth, and Cle Elum Ranger Districts. The Naches-Tieton Working Circle includes the Naches Ranger District.

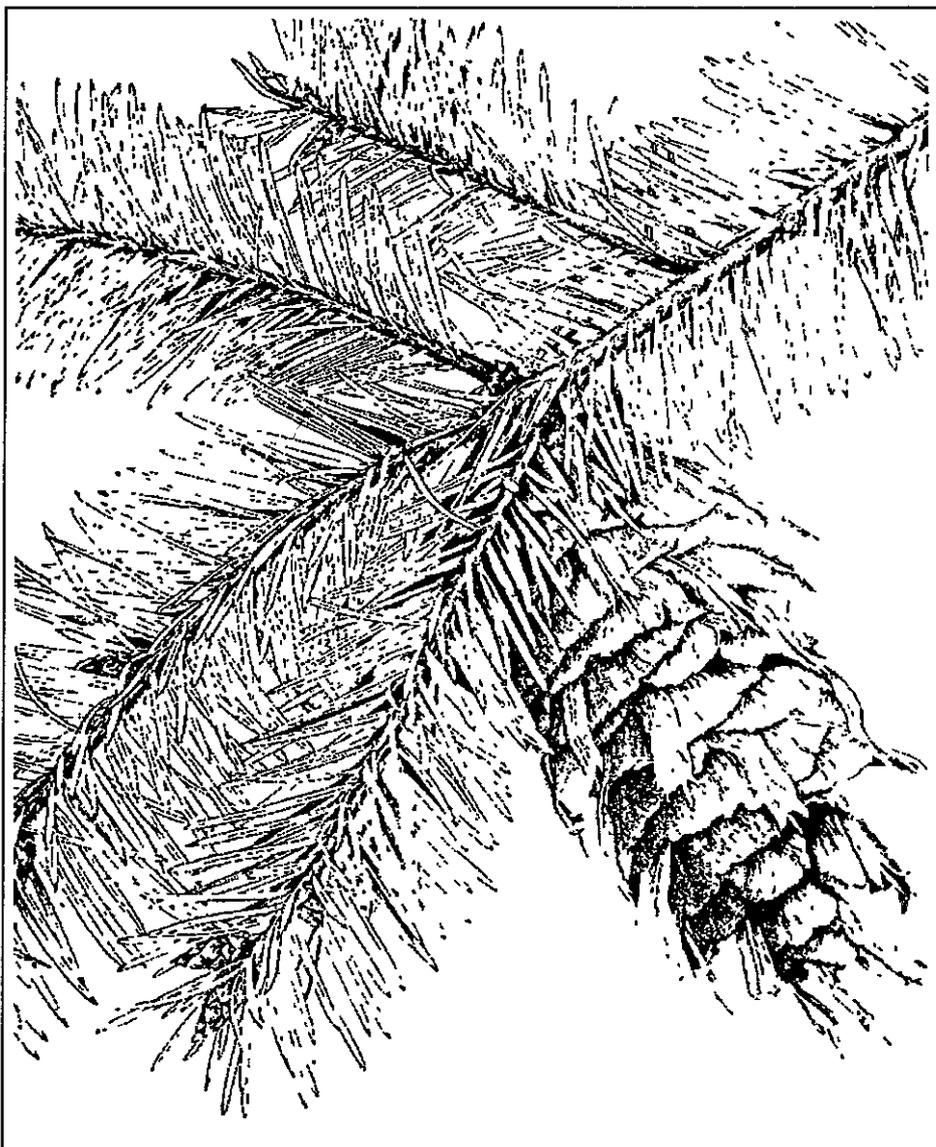

Y

YAKIMA INDIAN TREATY RIGHTS AREA - Those lands on the Wenatchee National Forest where the Yakima Indian Nation retained certain use rights under Article 3 of the Yakima Indian Treaty of 1855.

YIELD TABLES - Tables that estimate the level of outputs that would result from implementing a particular activity, yield tables can be developed for timber volumes, range production, soil and water outputs, and other resources.

Z

ZONE OF INFLUENCE - The geographic area whose social, economic and/or environmental condition is significantly affected by changes in Forest resource production or management.

APPENDIX A

The following activity schedules represent a pool of possible projects necessary to achieve the outputs contained in Table IV-2 of Chapter IV. You may note that the outputs projected are not always exactly identical to those in Table IV-1 of this Plan and Alternative C in the FEIS. The differences result from the approximations of the FORPLAN Model as compared to the reality of implementing the objectives of the preferred alternative on-the-ground. However, the schedules do approximate the outputs over the ten year period.

The cost of implementation of these projects in addition to General Administration and monitoring costs approximate the budget required to implement this Plan. If budgets are significantly different than those contained in this Plan, some projects will not be accomplished, which will result in a reduction in expected outputs, and the corresponding objectives of the Plan will not be met.

The project schedules were derived from existing action plans and inventories, and most are accurate for the first three to five years. In some cases, the project list calls for new inventories or resource plans, which will result in new projects and in new priorities. This will necessitate updating the schedules periodically as new inventories and analysis are completed. It is expected that the detailed schedules will require updating annually as a result of the budget process and new action plans.

RECREATION CONSTRUCTION PROJECTS

Region Capital Investment Program 1/

Project Name	District	Construction Cost (in Thousands)	
		First Five Yrs	Second Five Yrs
Boat Launch Extensions	Chelan	356.0	
Cottonwood Campground	Entiat	253.0	
Fields Point Phase III	Chelan	200.0	
Icicle/Lake Wenatchee	Leaven/Lake	117.0	
Kachess Campground	Cle Elum	1,080.0	
Lake Chelan Rec. Sites	Chelan	1,000.0	
Pleasant Valley/Bumping/ Halfway/Lodgepole	Naches	669.0	
Rimrock/Bumping Boat Ramps	Cle Elum	114.0	
Speelyii Beach	Cle Elum	56.0	
Three Creeks Campground	Entiat	162.0	
Wenatchee River Campground	Lake Wenatchee	750.0	
Kaner Flat ORV (IAC)	Naches	240.2	
Rock Creek Horse Camp	Lake Wenatchee	150.0	
Campground Paving	Leavenworth		92.0
Fish Lake Campground	Lake Wenatchee		249.0
Handicapp Facilities	Cle Elum		107.5
River Bend Campground	Lake Wenatchee		100.0
West End Group Site	Leavenworth		222.5
Clear Lake Rec. Site	Naches		325.0
South Navarre Campground	Chelan		57.0
Pine Flat Campground	Entiat		376.0
North Fork Campground	Entiat		318.0
Salmon La Sac Campground	Cle Elum		1,000.0
Tronson/Bonanza	Leavenworth		200.0
Crow Creek Campground	Naches		108.0
Little Naches Campground	Naches		150.0
Longmire Meadow Campground	Naches		125.0
Lost Meadow Campground	Naches		705.5
Quartz Creek Campground	Naches		75.0
South Shore Campground	Chelan		50.0
Antilon Lake Campground	Chelan		50.0
Owhi Campground	Cle Elum		50.0
Peninsula Campground	Naches		50.0
Dog Lake Campground	Naches		125.0
White Pass Horse Camp	Naches		100.0
Milk Pond Campground	Naches		50.0

1/ Does not include cultural resource projects or wilderness rehabilitation projects.

RECREATION CONSTRUCTION PROJECTS

Region Capital Investment Program 1/

Project Name	District	Construction Cost (in Thousands)

- 1/ Surveys in support of timber should precede, by at least two years, the anticipated timber sell date to allow time to complete any mitigation needed Use 10 year timber sale action plan to schedule surveys and District targets.
- 2/ Surveys are in support of trail construction/reconstruction and construction or expansion of developed recreation sites. Trail corridors include survey of 250 feet either side of centerline Refer to the 10 year schedule of recreation projects to schedule surveys and District targets
- 3/ Surveys are in support of the land exchange program To the extent possible, these should be scheduled 2 years in advance of any particular exchange to allow time to complete any mitigation needed.
- 4/ Surveys that are not tied to project support should emphasize Wilderness and roadless areas since inventory here has been limited to date
- 5/ Surveys are in support of fish habitat improvements, range improvements minerals and special use permit administration
- 6/ This category includes either the recordation of new sites or the revision of currently inadequate site inventories to Regional standards
- 7/ Where functional administrative buildings are involved plans will be coordinated with the District facility operations and maintenance plans
- 8/ Evaluation priorities will be based on a) sites falling within or adjacent to a proposed project area. b) sites easily accessible to the public and hence subject to vandalism, c) sites experiencing various levels of natural degradation; and d) remaining sites By 1990 evaluations will be based on groups of sites for which a common thematic context has been developed
- 9/ Six of these projects are in support of the recreation capital investment construction program; the remaining projects are in conjunction with an archaeological site where there is a substantial threat of vandalism and an archaeological site undergoing substantial river erosion.
- 10/ These projects include interpretation through a variety of media signs, displays, cassette and video tapes, brochures, maps, visitor centers, rehabilitations and even reconstructions

A-18

1/ Structures include such things as spring developments, gates for blocking roads, nest boxes for various bird species etc. There is a great range in the number of structures required to treat an area and the cost of each structure. Consequently the values for number of structures and costs are highly variable within and between Districts.

Proposed Ten Year Timber Sale Schedule
1990-1999

This appendix provides information on individual planned and proposed timber sales. These sales are at various stages of preparation. For example, some sales for 1990 have all the field work completed while others, especially miscellaneous and salvage sales, may not have any field work done at this time. In general, the farther into the future a sale is scheduled the less complete is the information.

Alternative C, the preferred alternative in the FEIS, has an annual sale quantity volume of 136 MM board feet or 24.3 MM cubic feet. A phase down to this volume is planned during 1990 when 141.7 is proposed. In addition, an approximately 10 mm Bd. ft of firewood, pulp, and other nonchargeable volume is proposed for sale each year.

The FORPLAN model schedules clearcut harvests on 3,433 acres and shelterwood for 2,360 per year in the first decade. The proposed Ten Year Timber Sale Program schedules 2,719 clearcut acres with 2,697 acres seed tree or shelterwood cut (shelterwood and clearcut).

The difference in harvest acres between FORPLAN and the ten-year schedule is due mostly to sanitation salvage and selection harvest or uneven-aged management which are not modeled in FORPLAN.

The management area(s) (allocation) listed is/are the principal area(s) proposed for the sale. Most sales will have minor amounts of riparian allocations included in the sale area.

A summary of proposed sale volume is shown in the following tables.

Maps of the general sale locations are available for review at the Forest Supervisor's Office.

The following are abbreviations used in the Tables:

HCC - Harvest by Clear Cutting	DF - Douglas-fir
HSH - Harvest by Shelterwood Seed Cutting.	AF - Sub-Alpine fir
HPR - Harvest using other Partial Removal methods including final removal of overstory trees, thinning and uneven-aged management selected harvest.	PP - Ponderosa Pine
HFR - Harvest removing all large trees but leaving an understory of young seedlings.	LPP - Lodgepole Pine
ORS - Overstory removal cutting.	PSF - Pacific silver fir
	WH - Western hemlock

**VEGETATION MANAGEMENT PRACTICES
(ANNUAL AVERAGE IN FIRST DECADE FOR SUITABLE LANDS)**

Practice	Acres
Regeneration harvest:	
Clearcut	2,719
Shelterwood and seed tree	
- Preparatory cut	100
- Seed Cut	2,697
- Removal cut	2,320
Selection	112
Intermediate harvest:	
Commercial thinning	252
Salvage/sanitation	210
Timber stand improvement	<u>4,200</u>
Reforestation	<u>4,300</u>

Based on the 10 year action schedule the Ranger Districts estimate 2,719 acres of clearcut harvest. This is about 32 percent of the acres planned for harvest. Clearcutting reduces damage to future stands from dwarf mistletoe. Manipulation of species composition by planting can also reduce future losses to root disease and can be accomplished best using either shelterwoods or clearcut methods.

Shelterwood cutting can be done in two or three steps. As shown in Table IV-8, most of the Forest's planned shelterwoods in the next 10 years involve only seed cut and final removal. Preparatory cuts are seldom used due to the extra cost of a third entry into the stands. An additional entry also increases risks of soil compaction and wildlife disturbance.

Commercial thinning is also little used in the pure sense on the Forest. Few acres were selected by FORPLAN for commercial thinning. Based on maximizing present net value, approximately 3 percent or 252 acres of the general forest area are planned for commercial thinning. Additional commercial thinning could increase yields and revenues, but the costs exceed the benefits at the present time on most acres. Most of the current commercial thinning planned is for metallurgic chips from overstocked stands. Both direct costs and revenues are low for these sales as currently being prepared and administrated.

Salvage and sanitation acres are rough estimates and may be less than will actually be completed. These types of sales are in high demand by small operators as they usually required less capital and equipment than normal sales. Most people do not like to see forest residues from dead or windthrown trees accumulate and, therefore, salvage of this material has a higher acceptance by the public than harvest of "green" trees. However, greater

recognition of the need for wildlife trees and forest residue will keep salvage at a lower level than in the past.

"Selection" cutting or unevenaged management acres are probably the most difficult to predict. These will be identified on a site specific basis by the silviculturist on the Districts. Depending on definition, many of the acres managed for other resource emphasis will approach unevenaged management due to the long rotations and constant tree cover strived for. However, the primary difference between the proposed management and unevenaged management is that a definite heavy harvest to stimulate regeneration is planned on most of these acres. In pure unevenaged management a little regeneration is expected each year with no set "regeneration" cut proposed.

EARNED HARVEST

As shown in the monitoring plan, an increase or decrease of suitable acres or in intensive management of +10 percent will result in a recalculation of the annual sale quantity. Below is the calculation of the earned harvest factors

Calculation of the Earned Harvest Factors (EHF)

Planned Level: Includes prompt restocking with genetically selected planting stock on 75 percent of the clearcut and shelterwood acres. Precommercial thinning is proposed on 3,700 acres annually during the first decade. An estimated 500 acres of release is planned and often is done currently with thinning. These two items will be considered as an aggregate and termed timber stand improvement (T.S.I.). No fertilization is proposed at the planned level.

Earned Harvest Adjustment Level: If timber stand improvement (release and precommercial thinnings) vary by more than +10 percent from the goal of 4,200 acres, and adjustment in the annual sale quantity will be made. This adjustment will be based on the change in potential yield for management with precommercial thinning (GF-1) and management without precommercial thinning (GF-4) based on the managed yield tables. This is approximately 553 cubic feet of increased wood for each acre precommercially thinned. This is based on approximately equal "dry" and "wet" thinning.

Therefore, an increase or decrease of +10 percent in timber stand improvement acres would translate to a 165.9 M cubic feet change in annual sale quantity, (300 acres x 553 = 165.9 M cubic feet or .9 MM board feet).

Precommercial Thinning Earned Harvest Factor = 553 cubic feet/AC treated.

Fertilization Earned Harvest Factor = 471* cubic feet/AC treated. As the base level is 0 treatment, any fertilization completed can be used to increase in the annual sale quantity. An increase in the sale quantity should be made when the increase from fertilization equals + 10 percent of the annual allowable quantity or 238 M cubic feet. This would occur with a threshold fertilization amount of approximately 2,000 acres per year.

* Based on research findings from operational fertilization on the Cle Elum Ranger District. Approximately equal to results Region-wide reported by Miller 1979.

APPENDIX B

LANDOWNERSHIP SITUATION

The land ownership guidance for the Forest is contained in the Forest management prescriptions for this Forest Plan. (See 24.81--J11 Landownership Planning in each prescription.) This language in the prescriptions directs every acre of the forest into one of the five (5) landownership classification categories defined on pages 100 and 101 of Chapter IV of this plan.

The location of the lands within each of these categories is shown on the Landownership Classification Map in this appendix.

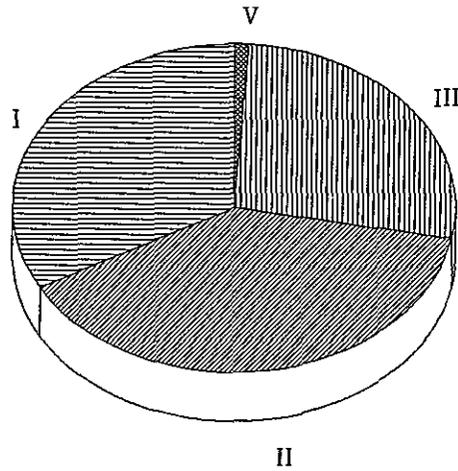

Total acreages by prescription and category are displayed on the pie chart in this appendix.

In addition, further guidance relating to the acquisition of recreation lands is contained in the Chelan, Lake Wenatchee, and Icicle Creek Composite plans. Copies of these documents are located at the Chelan, Lake Wenatchee, and Leavenworth Ranger Stations.

A projection of acres to be exchanged and purchased over the first decade of the plan follows. In the land exchange projection, the acres shown are the non-federal acres being acquired by the United States. A similar acreage of National Forest land should be considered as going into private ownership.

ACTIVITY	UNIT OF MEASURE	OUTPUT UNITS BY YEAR									
		1990	1991	1992	1993	1994	1995	1996	1997	1998	1999

LAND CLASSIFICATION

Category I lands are those within congressionally designated areas, for example a Wilderness. The direction for this category is to retain existing National Forest lands and acquire private inholdings.

Category II lands are those within administratively designated areas, for example, scenic areas, Mather Memorial Parkway, botanical areas and other lands which have been determined to be necessary for wildlife, visuals or recreation needs. Generally, in this category existing National Forest lands will be retained and private inholdings will be acquired. Acquisition of private lands in this category will be pursued as opportunities arise.

Category III lands are primarily within the land allocations where management direction emphasizes commodity production. The direction for this category is to avoid placing priorities on either retention or disposal of lands. Ownership changes in either direction may be appropriate. They will be considered on a case-by-case basis.

Category IV lands are National Forest lands which will serve the public interest best in private ownership and existing private lands which should remain in private ownership. The direction for this category is to transfer the National Forest lands into private ownership. The preferred method for accomplishing this is land exchange, thus advancing other land management goals at the same time. Examples of lands which fit this classification are:

- a. Isolated small parcels of land which are impractical to manage
- b. Parcels where a greater general public value can be derived in private ownership
- c. Areas necessary for community expansion

Category V lands are those which require an intensive study before priorities for ownership can be recommended. The direction for this category is to initiate the necessary studies at the earliest opportunity.

APPENDIX C

INTRODUCTION

The Wenatchee National Forest is within the area ceded to the U.S. Government by the Treaty with the Yakima, 1855. This treaty reserved to the confederated tribes and bands of the Yakima Indian Nation certain rights and privileges to these ceded lands. Among the most important rights with respect to management of the Forest are those identified in Article 3: "...the right of taking fish at all usual and accustomed places in common with the citizens of the territory, and of erecting temporary buildings for curing them; together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land..." This right includes consideration by the Forest Service of the environmental effects of their land management activities on the water quality and anadromous fish habitat of the Forest.

Certain additional uses of the Forest lands by the American Indians are authorized by P.L. 95-341, the Joint Resolution on American Indian Religious Freedom (AIRFA). This Act states that it shall be the policy of the United States to protect and preserve for American Indians their inherent right of freedom to believe, express and exercise their traditional religions. This includes, but is not limited to, access to sites, use and possession of sacred objects and the freedom to worship through ceremonials and traditional rites. This Act directs Federal Departments and Agencies to evaluate their policies and procedures in consultation with Native traditional religious leaders in order to determine appropriate changes necessary to protect and preserve Native American religious rights and practices.

The following are complete copies of the Treaty with the Yakima, 1855 and the American Indian Religious Freedom Act.

TREATY WITH THE YAKIMA, 1855

June 9, 1855

12 Stat. 961
Ratified Mar 8 1859
Proclaimed Apr 18,
1859

Articles of agreement and convention made and concluded at the treaty-ground, Camp Stevens, Walla-Walla Valley, this ninth day of June, in the year one thousand eight hundred and fifty-five, by and between Isaac L. Stevens, governor and superintendent of Indian affairs for the Territory of Washington, on the part of the United States and the undersigned head chiefs, chiefs, head-men, and delegates of the Yakama, Palouse, Pisuouse, Wenatshapam, Klikatat, Klinguit, Kow-was-say-ee, Li-ay-was, Skin-pah, Wish-ham, Shyiks, Oche-chotes, Kah milt-pah, and Se-ap-cat, confederated tribes and bands of Indians, occupying lands hereinafter bounded and described and lying in Washington Territory, who for the purposes of this treaty are to be considered as one nation, under the name of "Yakama," with Kamariakun as its head chief, on behalf of and acting for said tribes and bands, and being duly authorized thereto by them.

Cession of lands to
the United States

ARTICLE 1. The aforesaid confederated tribes and bands of Indians hereby cede, relinquish, and convey to the United States all their right, title, and interest in and to the lands and country occupied and claimed by them, and bounded and described as follows, to wit.

Boundaries

Commencing at Mount Ranier, thence northerly along the main ridge of the Cascade Mountains to the point where the northern tributaries of Lake Che-lan and the southern tributaries of the Methow River have their rise; thence southeasterly on the divide between the waters of Lake Che-lan and the Methow River to the Columbia River; thence, crossing the Columbia on a true east course, to a point whose longitude is one hundred and nineteen degrees and ten minutes, (119° 10'), which two latter lines separate the above confederated tribes and bands from the Oskinakane tribe of Indians; thence in a true south course to the forty-seventh (47°) parallel of latitude; thence east on said parallel to the main Palouse River, which two latter lines of boundary separate the above confederated tribes and bands from the Spokanes; thence down the Palouse River to its junction with the Moh-hah-ne-she, or southern tributary of the same; thence in a southeasterly direction, to the Snake River, at the mouth of the Tucannon River, separating the above confederated tribes from the Nez Percé tribe of Indians, thence down the Snake River to its junction with the Columbia River: thence up the Columbia River to the "White Banks" below the Priest's Rapids, thence westerly to a lake called "La Lac," thence southerly to a point on the Yakama River called Toh-mah-luke; thence, in a southwesterly direction, to the Columbia River, at the western extremity of the "Big Island," between the mouths of the Umatilla River and Butler Creek; all which latter boundaries separate the

TREATY WITH THE YAKIMA, 1855.

above confederated tribes and bands from the Walla-Walla, Cayuse, and Umatilla tribes and bands of Indians; thence down the Columbia River to midway between the mouths of White Salmon and Wind Rivers, thence along the divide between said rivers to the main ridge of the Cascade Mountains; and thence along said ridge to the place of beginning

ARTICLE 2 There is, however, reserved, from the lands above ceded for the use and occupation of the aforesaid confederated tribes and bands of Indians, the tract of land included within the following boundaries, to wit Commencing on the Yakama River, at the mouth of the Attah-nam River, thence westerly along said Attah-nam River to the forks; thence along the southern tributary to the Cascade Mountains; thence southerly along the main ridge of said mountains, passing south and east of Mount Adams, to the spur whence flows the waters of the Klickitat and Pisco Rivers, thence down said spur to the divide between the waters of said rivers; thence along said divide to the divide separating the waters of the Satass River from those flowing into the Columbia River; thence along said divide to the main Yakama, eight miles below the mouth of the Satass River; and thence up the Yakama River to the place of beginning.

All which tract shall be set apart and, so far as necessary, surveyed and marked out, for the exclusive use and benefit of said confederated tribes and bands of Indians, as an Indian reservation; nor shall any white man, excepting those in the employment of the Indian Department, be permitted to reside upon the said reservation without permission of the tribe and the superintendent and agent. And the said confederated tribes and bands agree to remove to, and settle upon, the same, within one year after the ratification of this treaty. In the mean time it shall be lawful for them to reside upon any ground not in the actual claim and occupation of citizens of the United States, and upon any ground claimed or occupied, if with the permission of the owner or claimant

Guaranteeing, however, the right to all citizens of the United States to enter upon and occupy as settlers any lands not actually occupied and cultivated by said Indians at this time, and not included in the reservation above named.

And provided, That any substantial improvements heretofore made by any Indian, such as fields enclosed and cultivated, and houses erected upon the lands hereby ceded, and which he may be compelled to abandon in consequence of this treaty, shall be valued, under the direction of the President of the United States, and payment made therefor in money; or improvements of an equal value made for said Indian upon the reservation. And no Indian will be required to abandon the improvements aforesaid, now occupied by him, until their value in money, or improvements of an equal value shall be furnished him as aforesaid.

ARTICLE 3. *And provided,* That, if necessary for the public convenience, roads may be run through the said reservation; and on the other hand, the right of way, with free access from the same to the nearest public highway, is secured to them; as also the right, in common with citizens of the United States, to travel upon all public highways

The exclusive right of taking fish in all the streams, where running through or bordering said reservation, is further secured to said confederated tribes and bands of Indians, as also the right of taking fish at all usual and accustomed places, in common with the citizens of the Territory, and of erecting temporary buildings for curing them, together with the privilege of hunting, gathering roots and berries, and pasturing their horses and cattle upon open and unclaimed land.

Reservation.

Boundaries

Reservations to be set apart etc., and Indians to settle thereon
Whites not to reside thereon

Improvements on ceded lands

Roads may be made

Privileges secured to Indians

TREATY WITH THE YAKIMA, 1855

Payments by the United States

ARTICLE 4. In consideration of the above cession, the United States agree to pay to the said confederated tribes and bands of Indians, in addition to the goods and provisions distributed to them at the time of signing this treaty, the sum of two hundred thousand dollars, in the following manner, that is to say: Sixty thousand dollars, to be expended under the direction of the President of the United States, the first year after the ratification of this treaty, in providing for their removal to the reservation, breaking up and fencing farms, building houses for them, supplying them with provisions and a suitable outfit, and for such other objects as he may deem necessary, and the remainder in annuities, as follows: For the first five years after the ratification of the treaty, ten thousand dollars each year, commencing September first, 1856; for the next five years, eight thousand dollars each year; for the next five years, six thousand dollars per year; and for the next five years, four thousand dollars per year

How to be applied

All which sums of money shall be applied to the use and benefit of said Indians, under the direction of the President of the United States, who may from time to time determine, at his discretion, upon what beneficial objects to expend the same for them. And the superintendent of Indian affairs, or other proper officer, shall each year inform the President of the wishes of the Indians in relation thereto.

United States to establish schools

ARTICLE 5. The United States further agree to establish at suitable points within said reservation, within one year after the ratification hereof, two schools, erecting the necessary buildings, keeping them in repair, and providing them with furniture, books, and stationery, one of which shall be an agricultural and industrial school, to be located at the agency, and to be free to the children of the said confederated tribes and bands of Indians, and to employ one superintendent of teaching and two teachers: to build two blacksmiths' shops, to one of which shall be attached a tin-shop, and to the other a gunsmith's shop, one carpenter's shop, one wagon and plough maker's shop, and to keep the same in repair and furnished with the necessary tools, to employ one superintendent of farming and two farmers, two blacksmiths, one tinner, one gunsmith, one carpenter, one wagon and plough maker, for the instruction of the Indians in trades and to assist them in the same, to erect one saw-mill and one flouring-mill, keeping the same in repair and furnished with the necessary tools and fixtures, to erect a hospital, keeping the same in repair and provided with the necessary medicines and furniture, and to employ a physician, and to erect, keep in repair, and provided with the necessary furniture, the building required for the accommodation of the said employees. The said buildings and establishments to be maintained and kept in repair as aforesaid, and the employees to be kept in service for the period of twenty years

Mechanics' shops

Sawmill and flouring mill
Hospital

Salary to head chief house, etc

And in view of the fact that the head chief of the said confederated tribes and bands of Indians is expected, and will be called upon to perform many services of a public character, occupying much of his time, the United States further agree to pay to the said confederated tribes and bands of Indians five hundred dollars per year, for the term of twenty years after the ratification hereof, as a salary for such person as the said confederated tribes and bands of Indians may select to be their head chief, to build for him at a suitable point on the reservation a comfortable house, and properly furnish the same, and to plough and fence ten acres of land. The said salary to be paid to, and the said house to be occupied by, such head chief so long as he may continue to hold that office

Kamaiakun is the head chief

And it is distinctly understood and agreed that at the time of the conclusion of this treaty Kamaiakun is the duly elected and authorized

TREATY WITH THE YAKIMA, 1855.

head chief of the confederated tribes and bands aforesaid, styled the Yakama Nation, and is recognized as such by them and by the commissioners on the part of the United States holding this treaty, and all the expenditures and expenses contemplated in this article of this treaty shall be defrayed by the United States, and shall not be deducted from the annuities agreed to be paid to said confederated tribes and band of Indians. Nor shall the cost of transporting the goods for the annuity payments be a charge upon the annuities, but shall be defrayed by the United States

ARTICLE 6. The President may, from time to time, at his discretion, cause the whole or such portions of such reservation as he may think proper, to be surveyed into lots, and assign the same to such individuals or families of the said confederated tribes and bands of Indians as are willing to avail themselves of the privilege, and will locate on the same as a permanent home, on the same terms and subject to the same regulations as are provided in the sixth article of the treaty with the Omahas, so far as the same may be applicable

Reservation may be surveyed into lots and assigned to individuals or families

ARTICLE 7. The annuities of the aforesaid confederated tribes and bands of Indians shall not be taken to pay the debts of individuals.

Annuities not to pay for debts of individuals

ARTICLE 8 The aforesaid confederated tribes and bands of Indians acknowledge their dependence upon the Government of the United States, and promise to be friendly with all citizens thereof, and pledge themselves to commit no depredations upon the property of such citizens.

Tribes to preserve friendly relations

And should any one or more of them violate this pledge, and the fact be satisfactorily proved before the agent, the property taken shall be returned, or in default thereof, or if injured or destroyed, compensation may be made by the Government out of the annuities.

To pay for depredations

Nor will they make war upon any other tribe, except in self defence, but will submit all matters of difference between them and other Indians to the Government of the United States or its agent for decision, and abide thereby. And if any of the said Indians commit depredations on any other Indians within the Territory of Washington or Oregon, the same rule shall prevail as that provided in this article in case of depredations against citizens. And the said confederated tribes and bands of Indians agree not to shelter or conceal offenders against the laws of the United States, but to deliver them up to the authorities for trial

Not to make war but in self-defense

To surrender offenders

ARTICLE 9. The said confederated tribes and bands of Indians desire to exclude from their reservation the use of ardent spirits, and to prevent their people from drinking the same, and, therefore, it is provided that any Indian belonging to said confederated tribes and bands of Indians, who is guilty of bringing liquor into said reservation, or who drinks liquor, may have his or her annuities withheld from him or her for such time as the President may determine.

Annuities may be withheld from those who drink ardent spirits

ARTICLE 10. *And provided.* That there is also reserved and set apart from the lands ceded by this treaty, for the use and benefit of the aforesaid confederated tribes and bands, a tract of land not exceeding in quantity one township of six miles square, situated at the forks of the Pisuouse or Wenatshapam River, and known as the "Wenatshapam Fishery," which said reservation shall be surveyed and marked out whenever the President may direct, and be subject to the same provisions and restrictions as other Indian reservations.

Wenatshapam fishery reserved

ARTICLE 11. This treaty shall be obligatory upon the contracting parties as soon as the same shall be ratified by the President and Senate of the United States

When treaty to take effect

In testimony whereof, the said Isaac I. Stevens, governor and superintendent of Indian affairs for the Territory of Washington, and the undersigned head chief, chiefs, headmen, and delegates of the afore-

said confederated tribes and bands of Indians, have hereunto set their hands and seals, at the place and on the day and year hereinbefore written.

ISAAC I. STEVENS,
Governor and Superintendent. [L s]

American Indian Religious Freedom

• Act of August 11, 1978 (P L. 95-341, 92 Stat. 469; 42 U.S.C. 1996(note))

Whereas the freedom of religion for all people is an inherent right, fundamental to the democratic structure of the United States and is guaranteed by the First Amendment of the United States Constitution;

Whereas the United States has traditionally rejected the concept of a government denying individuals the right to practice their religion and, as a result, has benefited from a rich variety of religious heritages in this country;

Whereas the religious practices of the American Indian (as well as Native Alaskan and Hawaiian) are an integral part of their culture, tradition and heritage, such practices forming the basis of Indian identity and value systems,

Whereas the traditional American Indian religions, as an integral part of Indian life, are indispensable and irreplaceable,

Whereas the lack of a clear, comprehensive, and consistent Federal policy has often resulted in the abridgment of religious freedom for traditional American Indians;

Whereas such religious infringements result from the lack of knowledge or the insensitive and inflexible enforcement of Federal policies and regulations premised on a variety of laws;

Whereas such laws were designed for such worthwhile purposes as conservation and preservation of natural species and resources*but were never intended to relate to Indian religious practices and, therefore, were passed without consideration of their effect on traditional American Indian religions;

Whereas such laws and policies often deny American Indians access to sacred sites required in their religions, including cemeteries,

Whereas such laws at times prohibit the use and possession of sacred objects necessary to the exercise of religious rites and ceremonies;

Whereas traditional American Indian ceremonies have been intruded upon, interfered with, and in a few instances banned: Now, therefore, be it

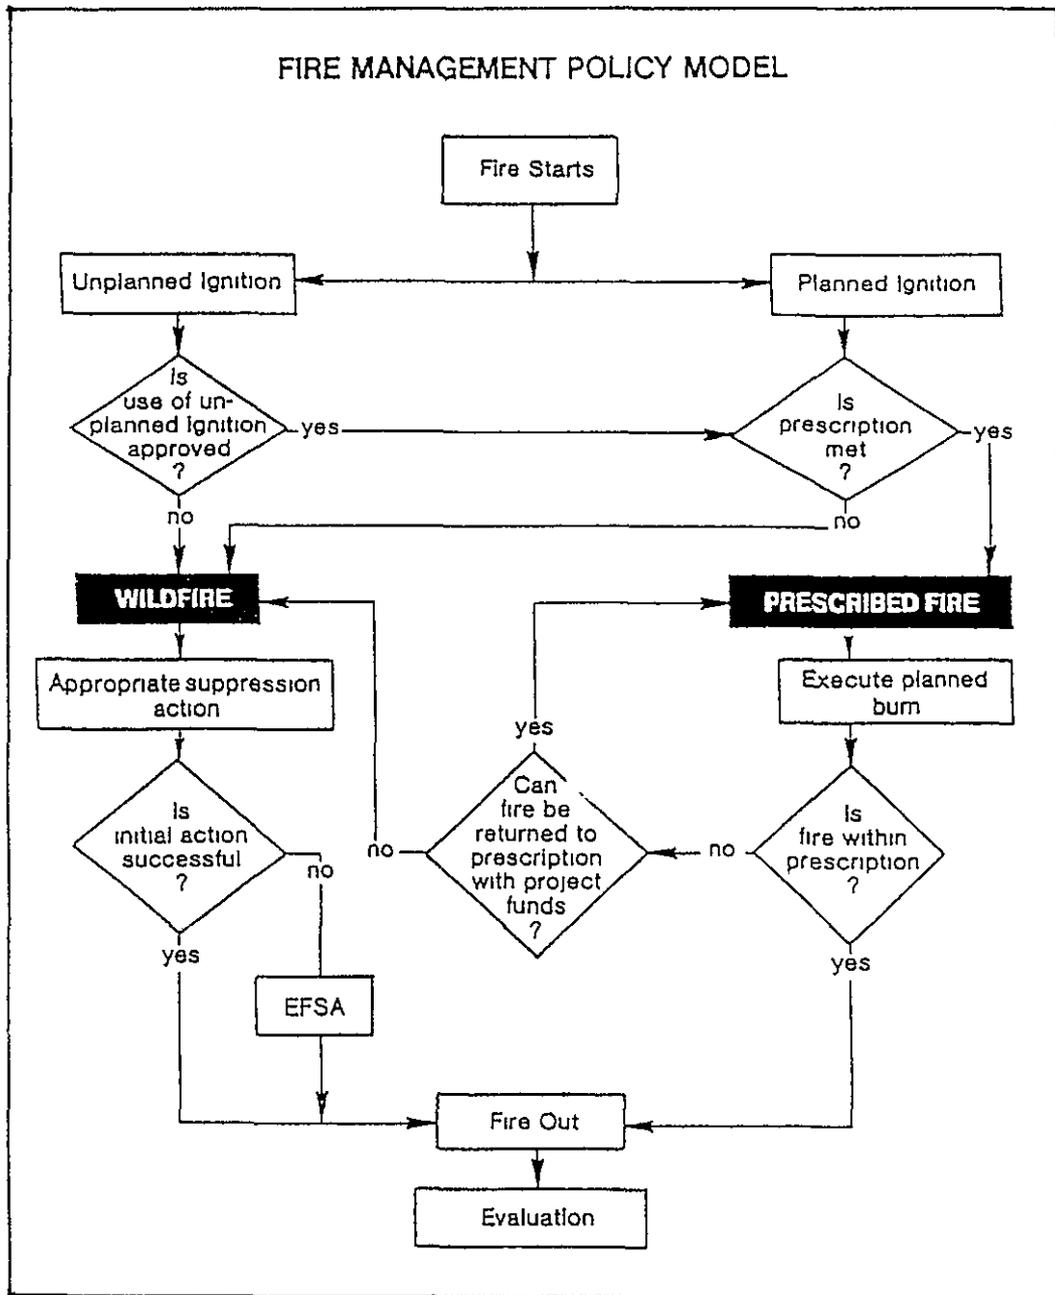

Resolved by the Senate and House of Representatives of the United States of America in Congress assembled,

That henceforth it shall be the policy of the United States to protect and preserve for American Indians their innerent right of freedom to believe, express, and exercise the traditional religions of the American Indian, Eskimo, Aleut, and Native Hawaiians, including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonials and traditional rites.

Sec. 2. The President shall direct the various Federal departments, agencies, and other instrumentalities responsible for administering relevant laws to evaluate their policies and procedures in consultation with native traditional religious leaders in order to determine appropriate changes necessary to protect and preserve Native American religious cultural rights and practices. Twelve months after approval of this resolution, the President shall report back to the Congress the results of his evaluation, including any changes which were made in administrative policies and procedures, and any recommendations he may have for legislative action.

APPENDIX D

The following is the fire management policy model (Matrix) referred to in the Protection section of Chapter IV.

APPENDIX E

WILDERNESS MANAGEMENT

A. WILDERNESS MANAGEMENT GOALS

1. Manage wildernesses to perpetuate wilderness character and wilderness resource values.
2. Manage wildernesses to allow natural ecological processes to operate freely and as independently of human activity as possible.
3. Manage wildernesses to provide opportunities for recreation experiences appropriate in wilderness.

B. WILDERNESS MANAGEMENT OBJECTIVES

1. Provide a variety of primitive recreation opportunities in a natural environment within the scope of the Wilderness Acts.
2. Provide a trail access system in wilderness that allows visitors to enjoy a variety of recreation experiences and minimizes negative impacts on wilderness resources.
3. Provide a range of challenges for wilderness users through trails of varying difficulty for foot, saddle and pack animal travel, and opportunities for cross-country travel.
4. Manage visitor use to ensure that physical and biological impact on the soil, vegetation, air, and water do not result in significant change in these resource values.
5. Manage visitor use to minimize social impact on recreation experiences and avoid user conflicts.
6. Restore and rehabilitate resource values degraded by present or past land management activity or recreation visitor use.
7. Manage human influences to maintain the system of natural processes that governs the distribution of plant communities and to insure that natural biotic communities and life cycles are undisturbed except by natural forces.

C. WILDERNESS RECREATION OPPORTUNITY SPECTRUM CLASSES

Individual wildernesses vary greatly in their degree of wilderness or pristine character, degree of isolation from the sounds and influences of people, and amount of recreation visitor use. There are also significant differences within each wilderness. The Wilderness Recreation Opportunity Spectrum (WROS) provides a way to describe these variations through the establishment of classes and the defining of resource and social conditions that exist in each class. All areas within each wilderness have been analyzed for the characteristics that are present in these areas and the physical, biological, and social conditions that are judged by wilderness managers to be necessary for each area, in order to meet wilderness management objectives. These present conditions and future objectives are then delineated as a class. Possible classes range from Pristine to Transition.

1. PRISTINE

The area is characterized as an extensive, unmodified, natural environment. Natural processes and conditions have not been measurably affected by the actions of users. The area will be managed as free as possible from the influences of human activity. Terrain and vegetation allow extensive and challenging cross-country travel.

This area provides the most outstanding opportunity for isolation, solitude, risk, and challenge. Encounters with other visitors will be infrequent.

There shall be no system trails in this class. Destination points will be accessed only by cross-country travel. Areas in this class are of sufficient size to assure a remote experience away from sights or sounds of human activity.

2. PRIMITIVE

The area is characterized by an essentially unmodified, natural environment. Concentrations of visitors are low and evidence of human use is minimal. The area has high opportunity for isolation, solitude, exploration, risk, and challenge.

This class receives very low visitor use due to low density of system trails and difficult terrain.

This class provides the user outstanding opportunities for cross-country travel, utilizing a high degree of outdoor skills often in an environment that offers a high degree of challenge and risk.

3. SEMI-PRIMITIVE

The area is characterized by a predominantly unmodified environment of at least moderate size. System trails and campsites are present and there is evidence of other uses. A minimum of on-site controls and restrictions are implemented to protect physical, biological, and social resources. Some facilities may be present to reduce visitor impact.

This class extends at least 500 feet on both sides of trail corridors, but may be wider around lakes, in drainage basins, and heavily used areas where the sights and sounds of people are noticed at greater distances.

A moderate to high degree of opportunity exists in this class for exploring and experiencing isolation from the sights and sounds of civilization. The environment offers a moderate to high degree of challenge and risk.

4. TRANSITION

The area is characterized by a predominantly unmodified environment, however, the concentrations of visitors may be moderate to high at various times. The area is characterized as having a large number of day users who are often mixed with overnight and long-distance travelers on trails near trailheads and wilderness boundaries.

The transition area is generally small and extends into wilderness a short distance to where side trails begin to distribute use. The class extends at least 500 feet on both sides of a trail and may be wider around lakes or heavily used areas.

Opportunities for exploration and experiencing isolation are reduced and visitors can expect to encounter the greatest number of people compared to other WROS Classes. This class introduces users to the wilderness setting, but the higher standard trails offer reduced challenge and risk.

TABLE E-1
ACRES IN EACH WILDERNESS RECREATION
OPPORTUNITY SPECTRUM CLASS BY WILDERNESS ^{1/}

Wilderness	Pristine	Primitive	Semi-Primitive	Transition
Lake Chelan-Sawtooth	5,510	29,520	17,350	1,340
Glacier Peak	148,220	79,490	46,700	6,570
Goat Rocks	10,050	15,810	9,430	1,050
Henry M. Jackson	4,160	16,000	5,760	1,280
Norse Peak	12,780	14,420	8,500	-0-
William O. Douglas	27,200	93,580	29,480	1,300
Total:	207,920	248,820	117,220	11,540

^{1/} Allocations for Alpine Lakes Wilderness are identified in the Alpine Lakes Management Plan.

D. GENERAL WILDERNESS MANAGEMENT

The wilderness Standards and Guidelines and management direction for the Wenatchee National Forest were coordinated with the Mt. Baker-Snoqualmie, Gifford-Pinchot, and Okanogan National Forests since the Cascade wildernesses in Washington State are located on portions of all four Forests.

The direction in this section applies to all wildernesses on the Forest except for the Alpine Lakes. Direction for management of this wilderness is contained in the Alpine Lakes Area Land Management Plan.

1. RECREATION

Wilderness provides unique and highly favored recreational experiences, however, recreational use of wilderness must be closely managed and monitored to assure that degradation of resource values does not occur. The following standards and guidelines are established to help achieve this end.

- a. If monitoring of on-site conditions indicates that wilderness resource values are being degraded or changed to a point that limits of acceptable change are being closely approached, management actions must be implemented to reverse the declining trend. Recreational visitor activities may be regulated, reduced, or excluded from specific sites or areas. Management actions designed to solve user impact problems will generally be fully implemented before entry quota systems are employed. (See Section H.)
- b. Visitor entry permit quotas should generally be applied to heavy use areas before they are applied to an entire wilderness.
- c. If it becomes necessary to establish priorities for wilderness visitation, highest priority should be given to uses which (1) least alter the wilderness environment and (2) are activities dependent upon the wilderness environment to be fully realized. Other uses should be encouraged to occur outside wilderness.
- d. Proposed temporary structures, such as corrals, hitch rails, or toilets must be necessary for the protection of wilderness resources and not for the convenience of users. Structures, if appropriate to the WROS Class, must be built of native or natural appearing materials and harmonize with the environment.
- e. Recreation visitors should not be permitted to cache or store equipment, personal property or supplies in wilderness. Caching is defined as leaving equipment unattended for more than 48 hours.
- f. Deviations or waivers from party size limitations may be approved by District Rangers. Waivers should consider the following criteria: (1) Capability of site and/or routes to withstand environment impacts, (2) Heavy use periods, (3) Heavy use areas, (4) Other parties on same route or destination at the same time, (5) Other visitors seeking solitude, (6) Areas not easily dominated by an oversized party, (7) Capacity of an area for camp sites and forage for livestock, (8) Action cannot be held outside wilderness, (9) Inter-district trips must be coordinated. Waivers should in no situation allow party size to exceed 12 people and 18 head of stock.

The following criteria should be used when considering waivers to allow caching of equipment in wilderness for a period longer than 48 hours.

1. Granting of the waiver is part of a managed corrective action aimed at getting control of historical occupancy and use problems.
2. The requested area is not highly controversial with the public.
3. The requested area is not located where there is frequent competition for available sites.
4. The site can accommodate the planned use.
5. The waiver will not exceed a length of stay prohibited by another order, ie: 14 Day Stay limit.
6. The site is not located in high visibility areas such as trail foregrounds, mountain passes or critical meadows.
7. The waivers can be monitored for compliance.
8. The waiver will facilitate an important wilderness enjoyment purpose, for which reasonable alternatives are lacking.

2. ADMINISTRATION

Ranger Districts will prepare annual Wilderness Management Action Plans for each wilderness. These plans will identify planned administrative actions, project work, and various management activities. Action Plans will be approved by the District Ranger.

Management activities and regulations should be coordinated with adjoining National Forests and Ranger Districts sharing management of wildernesses to ensure reasonable uniformity where necessary.

All administrative activity shall be conducted to minimize impact on social and biological resources. Wilderness Ranger patrols will conform to the Management Controls direction identified for each WROS Class.

Facilities such as cabins, trail shelters, or corrals, will not be constructed or maintained for administrative purposes. The wildernesses of the Forest are not of sufficient size or of sufficient logistical complexity to warrant these structures in wilderness.

Forest management activities outside of wilderness that influence the administration and visitor use of wilderness, will carefully consider potential negative impacts on wilderness resources in the planning phases.

Temporary signs, twine, stakes, matting, etc., used in site rehabilitation, may be necessary to inform the public and meet revegetation objectives. Visitor awareness of on-going rehabilitation projects should begin with District Receptionists and be carried through in trailhead information and wilderness Ranger contacts.

Permitted, but non-conforming, uses specified in the Wilderness Act will be administered to minimize negative impacts on wilderness. They will be reviewed and acted upon on a case-by-case basis.

3. SIGNING

Rough cut, chamfered edge, unfinished white oak shall be the standard sign material in wilderness. Lettering should be routed and scorched to a blackened color. Pacific Crest National Scenic Trail logo will be branded on white oak.

White oak signs should be placed on trees whenever possible. Where posts are necessary, use untreated native material that will weather over time.

All existing signs should be individually evaluated to determine if they meet signing objectives. Signs that do not meet the design and material standards should be scheduled for replacement with the objective of having all signs up to standard in three to five years. The number of signs should conform to standards for each WROS Class. The users should be allowed appropriate opportunities for discovery.

Mileages shall not be placed on signs within wilderness.

Signs needed for management and regulation of use, including site restoration areas and trail closures, shall be the minimum size possible, be easily seen and shall be installed to minimize both physical impact on the site and psychological impact on the users. Whenever possible, universal symbols should be used and signs worded in a positive tone. Signs will be removed when their purpose is completed.

Direction signs at system trail junctions should be limited to two per junction with a maximum of two route indicators per sign. Signs should not be used to direct users to trailless areas or to destinations on non-system trails.

Wilderness boundary signs should be placed at sufficient locations and distances so that outside activities will not encroach upon the wilderness. In the case of other management activities, project planning should include boundary posting.

Identification of hazardous stream crossings, trail conditions, prescribed fires or other information for the benefit of wilderness visitors will occur at trailhead bulletin boards or in recreation information handouts.

Emergency signing may be posted in the most logical place to be readily observed by Wilderness visitors.

4. CULTURAL RESOURCES

The preservation of cultural resources for enjoyment and educational purposes is an objective of wilderness designation. Historical structures and Native American sites must be managed and protected in accordance with State and Federal Law, and also in keeping with the intent of the Wilderness Act. All structures that have potential historical significance should be inventoried and evaluated. After evaluation, any decision to abandon or remove structures which meet the criteria for the National Register shall be preceded by the process outlined in 36 CFR 800. Any retained or maintained structure shall be managed to have a minimum impact on wilderness resources. If it is determined, after appropriate evaluation, that a structure is not of significance, it may be removed by a practical method compatible with the Wilderness Management Objectives. The decision to allow a structure that has cultural significance to gradually deteriorate is a management decision that must be preceded by proper evaluation.

Native American sites discovered at campsites or recreation use areas need to be protected and evaluated according to State and Federal laws.

5. TRAILS, BRIDGES, AND TRAVEL

Trails in wilderness are facilities or structures that allow adequate access for purposes of recreational use and enjoyment, and provide access for protection and administration. As well as providing access to destination points, trails can contribute to the recreation experience for many users. Trails, although generally necessary, do constitute a significant impact on physical and biological resources. Trails must be maintained, reconstructed, relocated, or new trails constructed in a manner that minimizes the impact on soil, water, vegetation, and wildlife. Trails must be safe enough to accommodate the planned use but should also contribute to the risk and challenge of wilderness travel.

Trail purpose and management objectives will be established for each trail. These objectives will be key factors in determining the standard and maintenance level for each trail.

Trails will be managed to maintain a balanced spectrum of travel opportunities in accordance with WROS Class criteria, trail objectives, mode of travel, and destinations.

Trails should be reconstructed, rerouted, or eliminated as needed to protect the wilderness resource and meet the objectives of each WROS Class. Priorities should be identified in the Wilderness Action Plans.

Bridge and footlogs may be provided to meet Wilderness Management Objectives and when no other route or crossing is reasonably available for visitor safety. Bridges should not be installed for visitor convenience or installed to extend the use season unless necessary to meet management objectives.

Trail locations and relocations should avoid wet areas and meadows. New trail drainage structures should be constructed of native materials and designed to minimize visual obtrusiveness. Existing metal or fiber drainage structures will be replaced where trail reconstruction becomes necessary and will be hidden from view until replaced.

Existing trails no longer needed or no longer compatible with WROS objectives should be restored to as near natural state as possible and monitored for use periodically.

The Pacific Crest National Scenic Trail shall be maintained to conform with the Wilderness Management objectives for the area which the trail passes through. Trail objectives and WROS class criteria will be the guiding direction for maintenance standards.

6. VEGETATION

Care should be taken to avoid the introduction of non-native plant species into wilderness. To minimize the possibility of accidental introduction through saddle and pack animal feed, the use of hay and unprocessed grain will be prohibited.

The use of processed grains and pelletized feed should be included in information provided to horse and pack animal users and outfitter-guide operations.

The areas surrounding campsites should be closely monitored for the presence of a near natural component of dead, deteriorating, woody debris. Areas lacking this component will be closed to campfires until natural accumulation recovers and excess wood is available. This requires some subjective judgment and is a factor in monitoring impact of visitor use.

7. FISH AND WILDLIFE

The Forest and Ranger Districts shall continue to work closely with the Washington State Departments of Wildlife and Fisheries in all aspects of fish and game management in wilderness. Ranger District action plans shall address specific coordination needs. Recommendations to State agencies will be based on protection of wilderness resources. Hunting, trapping, and fishing shall be permitted in accordance with State laws and regulated by State Agencies.

Management of native wildlife species is stressed. Wildlife species may be reintroduced if the species was once indigenous to an area and was eliminated through man's influence. Mechanized or motorized transport may be used with Regional Forester approval for reintroductions if use of non-motorized equipment is not feasible. Reintroduction should favor federally listed threatened or endangered species.

Fish stocking programs in lakes or streams should be developed in coordination with the State and in concert with Wilderness Management Objectives. This coordinated planning will be documented in annual action plans. Fish stocking programs will be administered under the direction provided in FSM 2323.34.

Fish and wildlife habitat manipulation projects can occur if they are done to perpetuate wilderness resources, to change a condition resulting from abnormal human influences, and if they meet the criteria identified in FSM 2323.35. These projects require approval from the Chief of the Forest Service. 

Trails and camping areas should be located so as not to reduce wildlife habitat effectiveness.

8. RECREATION LIVESTOCK GRAZING

Education of saddle horse and pack animal users will be an emphasis item during the life of this plan. Grazing and tethering of recreation livestock have the potential to result in significant impact on vegetation, soil, and water resources in a very short time period.

Horse and pack animal users should follow, at a minimum, the following practices:

- a. Avoid picketing or tying animals to feed in one location for a long period of time. Hobble animals or allow them to roam free during feeding periods.
- b. Do not graze, hitch, tether, or hobble any pack or saddle livestock within 200 feet slope distance of the shoreline of any lake.
- c. Tie stock on well-placed high lines during periods when not feeding.
- d. Feed animals in nose bags or feed bags to avoid littering a site.

Horse and pack animal users should generally be encouraged to pack in their basic feed supply for a trip, relying on available forage as a supplement. In heavily used areas and areas where forage is in short supply, the total feed needs of the animals should be packed in. Packing in feed usually requires additional animals. In making decisions regarding feed packing requirements, be mindful of the potential physical and biological impact of additional animals as well as the larger party size.

9. PERMITTED LIVESTOCK GRAZING ALLOTMENTS

Grazing allotments authorized within wilderness will be managed to blend with Wilderness Management Objectives. Forage utilization by permitted livestock will not be allowed to result in vegetative change that constitutes degradation of wilderness resource values.

Allotment Management Plans will address all stocking levels, maintenance and reconstruction of range improvements, and allotment management practices necessary on the allotments. These plans will describe all management activities necessary to meet allotment objectives and Wilderness Management Objectives.

Forage utilization will be monitored in the process of allotment inspection. Appropriate adjustments in grazing systems or permitted livestock numbers will be made to assure the protection of wilderness resource values.

10. WATER QUALITY

Human activity should not influence the natural quality of any waters within wilderness beyond temporary changes that return to normal when activity ceases.

Constructed facilities such as trails or high-use campsites have high potential to result in accelerated erosion rates that are detrimental to water quality. Areas used by recreation visitors will be closely observed for evidence of accelerated erosion. Water sources and water bodies near campsites should be observed for evidence of soap, other chemicals, and biological contaminants that may be introduced by human activity.

Wilderness Action Plans will identify management actions to be implemented to correct water quality problems. Methods will be developed in the future to monitor physical, chemical, and biological changes in water quality.

11. AIR QUALITY

Air quality in wilderness resulting from outside activities will be maintained to the Federal Clean Air Act and State Air Quality Standards.

Air quality impact resulting from recreation use, generally campfire smoke, will not be allowed to significantly deteriorate the recreation experience of wilderness visitors. Wilderness Action Plans will identify management actions to be implemented should excessive reduction of air quality occur.

Research is currently in planning phases to develop technology and methods to monitor air quality. Air quality related values have been identified for each Class I Wilderness and monitoring protocols are being developed.

12. FIRE MANAGEMENT

Natural fires have been an important force in the determination and evolution of the ecosystems present in wilderness. Fire suppression actions conducted since the early 1900's have had significant influence on these natural processes. In an effort to reduce the influences of fire suppression on wilderness ecosystems, a program of fire management has been developed (FSM 2324).

The objectives of fire management in wilderness are to:

- a. Permit lightning-caused fires to play, as nearly as possible, their natural ecological role in wilderness.
- b. Reduce, to an acceptable level, the risks and consequences of wildfire within wilderness or escaping from wilderness.

Upon completion of Wilderness Fire Management Plans, naturally occurring fires will be managed as prescribed fires as long as Wilderness Fire Management Objectives are being met (FSM 2324.21). Wildfires or fires burning outside of prescribed conditions will be suppressed. Each natural occurring fire will be considered a prescribed fire until declared a wildfire. Under specific conditions, described in Wilderness Fire Management Plans, prescribed fires may be ignited by forest managers to meet specific wilderness objectives (FSM 2324.22). The cumulative effects of prescribed fire will be considered in the development of decision criteria for fire management plans.

Human caused fires (not ignited by management) will be suppressed.

Fire managers will implement suppression strategies which minimize resource loss and the cost of fire suppression. Suppression tactics will be employed that minimize impacts on Wilderness resource values.

Before natural occurring fires can be managed as prescribed fires, detailed fire management action plans will be prepared for each wilderness; except the Alpine Lakes Wilderness, which has an approved Fire Management Plan. These plans will identify the preplanned specific conditions that must first exist before a fire can be managed as a prescribed fire. Outside of these specific parameters and conditions, fires will be declared wildfires and suppressed. Prescribed fire management will be conducted under conditions defined in FSM 2324.2.

13. RESEARCH

Research projects in wilderness require approval by the Regional Forester. Those applications for research that are wilderness dependent and compatible with Wilderness Management Objectives will be recommended for approval.

Research that helps resolve wilderness management problems or basic research on wilderness resources shall be given highest priority.

Data collected for management purposes, such as use figures and ecological data, should be made available to scientists for research purposes.

All research projects which require public contact, specimen collection, ground reference marking, or exemption from any regulations shall be conducted under a Special-Use Permit.

14. RECREATION SPECIAL-USE PERMITS

Recreation Special-Use Permits may be issued for specific recreation activities which are appropriate in wilderness, wilderness dependent, and in conformance with management objectives. Activities most typical are outfitter-guide operations.

Permits will not be issued for recreation events and competitions such as endurance races, competitive trail rides, rock climbing competition, running events, military exercises, or survival exercises.

15. OUTFITTER-GUIDE PERMITS

Permitted outfitters and guides provide valuable recreation opportunities for a segment of the public who do not have the expertise, equipment, or physical capabilities to enjoy these experiences on their own. Many of these opportunities are appropriate in wilderness within certain parameters, and many are dependent on the wilderness environment. Outfitter guides will continue to provide recreation opportunities in response to public demand for these opportunities.

Outfitter-Guide Permits should be issued or continued when:

- a. There is a demonstrated public need or demand for the service.
- b. Permitted use is compatible with general public use.
- c. Permitted use can occur in an area without exceeding the carrying capacity of an area in Persons-At-One-Time.
- d. Permitted use will not generate unacceptable impact on wilderness resources or changes that approach limits of acceptable change.

The number of permits issued and the amount of use allocated to permit holders should be evaluated periodically to assure an appropriate balance is maintained between general public use and outfitter use. Outfitter guides should not be allowed to dominate the use of an area or occupy favored campsites to the point that use by the general public is limited or constrained.

Outfitter-guide camps should be located away from other popular visitor campsites to reduce social resource impact.

Outfitter-guide permittees should actively assist in the education of wilderness visitors, within the scope of their operations.

Outfitter-guide operations will generally be required to adhere to established party size limitations and use conditions specified for each wilderness. Any deviation from caching or party size limitations must be documented in the annual operating plan and approved by the District Ranger.

16. VISUAL OBJECTIVES/SCENIC QUALITIES

The visual and scenic qualities present in wilderness are very significant to the quality of the recreation experience achieved by visitors. Recreation visitors should be encouraged through educational information and contacts to follow a few basic principles:

- a. Locate campsites away from and out of site of, trails, lakeshores, other campsites, and other points of interest.
- b. Tie or high-line horses and pack animals out of sight of trails, lakeshores, campsites and other points of interest.
- c. Leave no trace or evidence of their visit.
- d. Use equipment that is earth tones in color; avoid bright reds, oranges, blues and yellows.

Facilities and structures built for protection of resource values should be located to the extent practical in areas where visual impact will be minimal.

Trails should be located to take advantage of outstanding views or scenic features of high interest.

Natural events and processes such as rock slides, avalanches, tree mortality due to insects and disease, or fire, will change the visual conditions present. These natural occurrences will not be considered as detrimental to visual qualities. Special management actions should not be taken to mitigate or repair visual damage.

17. MINERALS AND ENERGY

Wilderness areas designated as such under the Wilderness Act were withdrawn from mineral entry on January 1, 1984. New wilderness areas established by the Washington State Wilderness Act were withdrawn from mineral entry as of the date of that Act of 1984. Except when valid prior-existing rights have been established and confirmed (eg, valid mining claims located or mineral leases issued prior to the date of withdrawal), wilderness-impacting mineral and energy resource exploration and development, mining claim location and mineral leasing are precluded. Valid existing rights for leases and permits will depend upon the date of issuance. Valid existing rights for mining claims will be determined by ensuring the date of location precedes the date of withdrawal, by ensuring all mining claim recording requirements have been met, and by confirming through a mining claim validity examination that a "discovery" of a valuable mineral was made prior to the date of withdrawal.

When proposed mineral-related activities require the use of mechanized or motorized equipment or will cause impacts to the wilderness characteristics, a plan of operation must be submitted, processed and approved. During the evaluation of such a proposal not only will the environmental consequences be assessed and valid existing rights to conduct such activity confirmed prior to approval, but a determination will be made as whether the use of such equipment is reasonably necessary for and incidental to the level of exploration or development activity being proposed.

Management objectives for the administration of mineral activity in wilderness are as follows:

- a. Mineral-related activities will be administered in compliance with all appropriate laws, regulations and Forest Service policy concerning wilderness management and the mining and mineral leasing laws.
- b. Those conducting mineral related activities will be required to meet all Federal and State water quality standards, and will be required to reasonably minimize any adverse impacts to wildlife habitat and the wilderness characteristics of the area.
- c. In keeping with any valid existing rights to operate mining claims or mineral leases, administrative efforts will be made to minimize any conflict between the mineral and the recreation users of wilderness areas.
- d. When mineral-related valid existing rights have been confirmed, they will be recognized; and our policy will be to encourage and facilitate those activities while ensuring any adverse impacts to wilderness are minimized. In meeting this objective the technological feasibility and the cost of implementing any enforceable controls will be considered and kept to a reasonable level.
- e. As time permits or as wilderness-impacting activities are proposed, valid existing rights on all unpatented mining claims located within wilderness areas will be evaluated. As part of the validity determination process, mining claimants will be contacted and given an opportunity to participate in that process.

18. WILD AND SCENIC RIVER CLASSIFICATION

Sections of rivers within wilderness are being recommended for classification as Wild Rivers under the Wild and Scenic Rivers Act. The designation of river segments as Wild Rivers is compatible with wilderness designation. Management decisions regarding land use or appropriate recreation activities will be directed by the act which has the most restrictive language regarding a specific question. Impoundment of rivers, which could be approved by the President under the Wilderness Act, Section 4(d)(4), would not be authorized on a river in wilderness designated Wild under the Wild and Scenic River Act, Section 7. Recreation use of a designated Wild River in wilderness may be regulated, if such use is creating impacts on wilderness resources that is not in keeping with the Wilderness Act. Management activities and recreation use impacts that occur on wild river segments within wilderness will be monitored for compliance with both Acts.

19. INSECTS AND DISEASE

There are three primary objectives in the management of insects and plant diseases in wilderness:

- a. Allow indigenous insect and plant diseases to play, as nearly as possible, their natural ecological role within wilderness.
- b. Protect the scientific value of observing the effect of insects and disease on the ecosystems.
- c. Control insect and plant disease epidemics that threaten adjacent lands or resources outside wilderness, or exotic pests that threaten an unnatural loss of wilderness resources.

When control measures are necessary in wilderness, they shall be carried out by measures that have the least adverse effect on wilderness resources and are compatible with Wilderness Management Objectives. Refer to FSM 2324.04, 2324.1, 2151, 3430, 1950.

20. THREATENED AND ENDANGERED SPECIES

Many wildernesses provide important habitat for threatened and endangered species of plants and wildlife. Actions necessary to protect or recover threatened or endangered species, including habitat manipulation and special protection measures, may be implemented in wilderness. Such actions must be necessary for perpetuation or recovery of the species and be actions that cannot be done more effectively outside wilderness. Refer to FSH 2309.19, 23.14, and 24.1.

21. SEARCH AND RESCUE

Search and rescue activities on National Forest Lands come under the jurisdiction of the County Sheriff in the county where an incident has occurred. The role of the Forest Service is to provide assistance, when requested, within the scope of the 1962 Memorandum of Understanding between the Forest Service and the Washington State Sheriff's Association. Procedures to follow in the event of a request for assistance from a Forest visitor in an emergency situation, are described in the Forest Mobilization Plan. Specific District procedures should be included in Annual Wilderness Action Plans.

Requests for use of motorized equipment or helicopters in search and rescue activities in wilderness, must be approved by the Forest Supervisor.

E. MANAGEMENT SPECIFIC TO EACH WROS CLASS

1. PRISTINE

a. Physical-Biological Standards

(1) Vegetation

- (a) Area of vegetation loss, and compacted bare mineral soil at any campsite, should not exceed 225 square feet.
- (b) Trampled area of vegetation with season recovery should not exceed 400 square feet.
- (c) No loss of trees, or trees with exposed roots at any campsite.
- (d) No noticeable modifications of natural plant succession due to stock grazing or human activity.
- (e) No loss of dead trees or noticeable loss of dead, woody debris due to campfires.

(2) Soils

- (a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates the natural process.
- (b) Soil compaction should not occur in this class outside existing established campsites.

(3) Water Quality

There should be no measurable change in water quality due to human activity.

(4) Air Quality

Air quality will not be degraded as a result of campfire smoke, or Forest Service Management activities outside of wilderness in Class I areas.

(5) Fish and Wildlife

Visitor use shall seldom and only temporarily displace wildlife populations.

(6) Visual Impact and Scenery

- (a) No campsites should be visible from any other campsite.
- (b) Human activity inside Wilderness should remain subordinate in foreground viewing and not be recognizable in middle-ground viewing areas.

(7) Livestock Allotment

This class should not include commercial livestock allotments so that the area is free as possible from human influences and to maintain the total integrity of natural ecological processes.

b. Social Standards

(1) Encounters

There should be an 80 percent probability that not more than one individual or party will be encountered per day during the primary use season.

(2) Party Size

The maximum party size shall not exceed a combination of 12 people and/or livestock, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness). A total of not more than six people will be encouraged in this class, and use of stock will not be encouraged for cross-country travel.

(3) Campsites

There shall be no other campsites visible or audible from any campsite. New user developed campsites will not be allowed to become established. When found, fire rings and tent frames will be disassembled and dispersed.

(4) Pets

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other resource impact.

c. Managerial Standards

(1) Regulations and Information

(a) *Posting of information and regulations regarding this class will be located at trailheads.*

(b) *Formal orders and permits may be required to achieve management objectives in this class.*

(c) *Ranger patrols and administrative contacts should be rare in this class and kept to the minimum necessary to meet management objectives.*

(d) *Signs will generally not be present, but may be used in rare circumstances to protect Wilderness resources.*

(e) *Recreation visitor travel routes will not be readily noticeable or may appear to be wildlife trails.*

(2) Trails

There shall be no system trails in this class. User travel should be managed so that travel routes are not readily apparent or appear to be wildlife trails.

(3) Resource Protection Facilities

Facilities such as stock holding corrals are not appropriate in this class. Areas receiving visitor use numbers sufficient that facilities are necessary to protect resources should not be classified Pristine, or use should be controlled to maintain pristine conditions.

Temporary signs may be necessary to inform visitors of soil and vegetation rehabilitation projects.

2. PRIMITIVE

a. Physical-Biological Standards

(1) Vegetation

(a) Area of vegetation loss, and compacted bare mineral soil at any campsite should not exceed 400 square feet.

(b) There should be no loss of trees at any site and fewer than four trees with exposed roots per impacted site.

(c) No noticeable, long-term modification of natural plan succession as a result of livestock grazing or human activity.

(d) Dead trees or dead, woody debris may be utilized for campfires in amounts that can be replaced annually through natural accumulation.

(2) Soils

(a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates natural processes.

(b) Soil compaction should not exceed limits which will prevent natural plant establishment and growth except at well established campsites.

(3) Water Quality

There should be no change in water quality except for temporary changes that return to normal when activity ceases.

(4) Air Quality

Air quality will not be degraded as a result of campfire smoke, or Forest Service Management activities outside of wilderness in Class I areas.

(5) Fish and Wildlife

Visitor use may temporarily displace wildlife, but should not displace wildlife from critical habitat during critical periods. (Such as fawning and winter range.)

(6) Visual Impact and Scenery

(a) Campsites will occasionally be visible from other campsites.

(b) Human activity should remain subordinate in foreground viewing and not recognizable in middle-ground viewing.

(7) Livestock Allotments

Commercial livestock is permitted in this class under approved management plans to the extent that this use is compatible with Wilderness resource values.

b. Social Standards

(1) Encounters

There should be an 80 percent probability that not more than either seven parties or seven individuals traveling alone will be encountered per day during the primary use season.

(2) Party Size

The maximum party size shall not exceed 12 people and/or livestock combined, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness).

(3) Campsites

There shall be no more than one campsites visible or audible from any campsite, or closer than 500 feet in open country.

(4) Livestock

Grazing stock is permitted except in established camp areas. Repeated stock use in cross-country travel by a single route shall be discouraged.

(5) Pets

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other resource impact.

c. Managerial Standards

(1) Regulations and Information

- (a) Posting of information and regulations regarding this class will be located at trailheads.
- (b) Formal orders and permits may be required to achieve management objectives in this class.
- (c) Ranger patrols and administrative contacts will occur periodically. Personnel involved in project work or monitoring will be present. Management personnel should conform to party size limitations and social standards for this class.
- (d) Signs will be kept to the minimum to protect Wilderness resources. No signs will be provided to indicate destinations.
- (e) Visitor travel routes may be noticeable, but should appear as wildlife trails.

(2) Trails

System trails are present in this class generally at low density. Some user developed trails may exist, but are not encouraged for use and rarely upgraded to system trails. If user-developed trails become well established, management action should be taken to rehabilitate damage and discontinue use. Reroutes of existing trails may be done to protect resources or to meet wilderness objectives. New trail construction in trailless drainages or to new destinations must be considered in the Forest Planning process.

(3) Resource Protection Facilities

Facilities that are essential for resource protection and visitor safety are appropriate in this class. Only native or natural appearing construction materials will be used. There will be no facilities provided for user comfort or convenience.

3. SEMI-PRIMITIVE

a. Physical-Biological Standards

(1) Vegetation

- (a) Area of vegetation loss, and compacted bare mineral soil at any campsite, should not exceed 625 square feet.
- (b) There should be no loss of trees at any site and only six trees per site with roots exposed or which show signs of human use impact.
- (c) There should be no long-term modification of plant succession and only short-term modification due to human activity or livestock grazing that can recover in one growing season.
- (d) Dead trees or dead, woody debris may be utilized for campfire wood in amounts that can be replaced annually through natural accumulation.

(2) Soils

(a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates natural processes.

(b) Soil compaction should not exceed limits which will prevent natural plant establishment and growth, except at desired campsites, and in designated trail treads.

(3) Water Quality

There should be no change in water quality except for temporary changes that return to normal when activity ceases.

(4) Air Quality

Air quality will not be degraded as a result of campfire smoke or Forest Service Management activities outside of wilderness in Class I areas.

(5) Fish and Wildlife

(a) Visitor use should not displace wildlife from critical areas during critical periods.

(b) Riparian areas should appear to be unchanged by human or livestock use.

(c) Displacement of wildlife due to visitor use may be significant but should be of short duration to assure a natural ecosystem is maintained. Visitor use should not decrease habitat effectiveness for one species more than 20 percent.

(6) Visual Impact and Scenery

(a) Campsites will be visible at times from other campsites.

(b) Human activity in wilderness, should remain generally subordinate in foreground viewing and not recognizable in middle-ground viewing.

(7) Livestock Allotments

Commercial livestock is permitted in this class under approved management plans to the extent that such use is compatible with all resource values.

b. Social Standards

(1) Encounters

There should be an 80 percent probability that not more than either ten parties or ten individuals traveling alone, will be encountered per day during the primary use season.

(2) Party Size

The maximum party size shall not exceed 12 people and/or livestock combined, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness).

(3) Campsites

There shall be no more than two campsites visible or audible from any campsite, or closer than 500 feet in open country.

(4) Livestock

Grazing of stock is permitted except in established camp areas.

(5) Pets

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other social or biological impact.

c. Managerial Standards

(1) Regulations and Information

(a) Posting of information and regulations regarding this class will generally be done at trailheads. Some regulatory signing may be posted at key locations such as lakeshores and campsites to help gain user compliance.

(b) Formal orders and permits may commonly be used to achieve management objectives in this class.

(c) Ranger patrols and administrative contacts will occur more frequently in this class, particularly at popular destination points and on weekends during the primary visitor use season. Personnel involved in project work or monitoring activities will be present. Major work projects should be planned as much as possible during low visitor-use periods. Management personnel should conform to party size limitations and be aware of their potential to impact visitor experiences.

(2) Trails

The managed trail system should be maintained or constructed toward more and most difficult trail standards (FSH 2309.18). However, trails classified easiest may exist in areas of gentle terrain and valley bottoms. A variety of user restrictions may be implemented to resolve negative resource impacts.

(3) Resource Protection Facilities

Facilities will be as natural appearing as possible or will be constructed out of native material. No facilities will be constructed for user convenience or comfort. Facilities will be placed so as to concentrate heavy impact on areas previously impacted and on sites capable of withstanding high impacts.

4. TRANSITION

a. Physical - Biological Standards

(1) Vegetation

- (a) Area of vegetation loss, and compacted bare mineral soil at any campsite, should not exceed 1000 square feet.
- (b) There should be no loss of trees at any site and only ten trees per site with roots exposed or which show signs of human use impact.
- (c) There should be no noticeable long-term modification of plant succession and only short-term modification due to human activity or livestock grazing, that can recover in one growing season.
- (d) Dead trees, or dead woody debris, may be utilized for campfire wood in amounts that can be replaced annually through natural accumulation.

(2) Soils

- (a) Displacement and erosion of soil resulting from human activity will be limited to a rate that approximates natural processes.
- (b) Soil compaction should not exceed limits which will prevent natural plant establishment and growth, except at desired campsites, and on designated trail treads.

(3) Water Quality

There should be no change in water quality except for temporary changes that return to normal when activity ceases.

(4) Air Quality

Air quality will not be degraded as a result of campfire smoke, or Forest Service Management activities outside of Wilderness in Class I areas.

(5) Fish and Wildlife

- (a) Visitor use should not displace wildlife from critical habitat areas during critical periods. If conflicts occur, management actions should be implemented to reduce the impact.
- (b) Riparian areas should appear to be unchanged by human or livestock use.
- (c) Displacement of wildlife due to visitor use may be significant but should be of short duration to assure a natural ecosystem is maintained. Visitor use should not decrease habitat effectiveness for one species more than 20 percent.

(6) Visual Impact and Scenery

(a) Campsites will be visible at times from other campsites.

(b) Human activity should remain generally subordinate in foreground viewing and not recognizable in middle-ground viewing.

(7) Livestock Allotments

Commercial livestock is permitted in this class under approved management plans to the extent that grazing use is managed to protect wilderness resource values.

b. Social Standards

(1) Encounters

There should be an 80 percent probability that not more than either 10-20 parties or 10-20 individuals traveling alone, will be encountered per day during the primary use season. Generally encounters should not exceed 10, however, in unique situations, encounters may reach 20 per day.

(2) Party Size

The maximum party size will not exceed 12 people and/or livestock combined, (12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness).

(3) Campsites

There shall be no more than three campsites visible or audible from any one campsite, or closer than 500 feet in open country.

(4) Livestock

Grazing of stock is permitted except in camp areas.

(5) Pets

Pets must be under reliable voice control or physical restraint. Pets may be banned from this class for protection of wildlife or to avoid other biological or social impact. Visitors will be encouraged to leave pets at home in areas of higher visitor use.

c. Managerial Standards

(1) Regulations and Information

(a) Posting of information and regulations will generally be posted at trailheads but some regulatory signing may be necessary in key impact areas, or areas where there is potential for use conflicts.

(b) Formal orders and permits will commonly be used to achieve management objectives and visitor compliance in this class.

(2) Administrative Presence

(a) Ranger patrols and administrative contacts will occur most frequently in this class, particularly in high day-use areas and popular destination points. Personnel involved in project work and monitoring activities will be present.

(b) Work projects should be planned to be completed during low visitor use periods to minimize impact on visitors.

(c) Management personnel should conform to party size limitations and be aware of their potential to impact visitor experiences.

(3) Trails

The managed trail system should be maintained or constructed toward more and most difficult trail standards (FSH 2309.18). Trails classified easiest may exist in areas of gentle terrain and valley bottoms. A variety of user restrictions may be implemented to resolve negative resource impacts.

(4) Resource Protection Facilities

Facilities will be natural appearing or will be constructed out of native material. No facilities will be constructed for user convenience or comfort. Facilities will be placed so as to concentrate heavy impact on areas previously impacted and at sites capable of withstanding high impacts.

F. LIMITS OF ACCEPTABLE CHANGE

Recreation visitor use of wilderness cannot occur without some degree of impact on wilderness resources. Impact occurs on the physical and biological features of wilderness as well as the quality of the recreation experience of other visitors. There is a point at which increasing impact of visitor use will result in unacceptable degradation outside the intent and direction of the Wilderness Act. The Regional Nondegradation Policy is described in FSM 2322.03.

The limits of acceptable change concept is a system to establish limits on the change that can be permitted within the nondegradation policy, before management actions must be taken to reverse trends of change. These actions can be either directed to improve the knowledge and abilities of the users or to reduce the numbers of visitors in impacted areas during critical time periods, or both.

The system has incorporated limits or maximum levels for which key indicator resource values can change before management actions are implemented. The system assumes that the condition of key indicators which are easily quantifiable and measurable reflect the general condition of resource values which are not easily measured. The impact of human-caused noise and human disturbance of wildlife are examples of impacts not easily measured.

The limits of acceptable change levels or standards are different for each Wilderness Recreation Opportunity Spectrum Class. The standards for the Pristine Class tolerate the least impact in order to achieve the most pristine wilderness conditions and the least evidence of man's activity. The Transition Class standards are more tolerant reflecting management of the area for a semi-primitive recreation experience and physical evidence of man's activity.

Table E-2 lists the key indicators that will be measured in monitoring the physical, biological, and social conditions and the standards for each Wilderness Recreation Opportunity Spectrum Class.

When monitoring results indicate that the condition of one or more of the key indicators is approaching the standard, or limit of acceptable change, a trend analysis will be done. This analysis will assess the changing conditions and identify all factors of visitor use contributing to the change. Cost effectiveness of possible management actions and recreation opportunity tradeoffs will be considered in the analysis. The analysis will identify alternative courses of action and a most suitable alternative will be chosen and implemented. Section H of this appendix explains potential management actions appropriate to resolve impact problems.

There is a high probability that initial monitoring results in some areas will indicate impact conditions in excess of standards established for particular WROS Classes. In this event, monitoring efforts will need to be intensified to establish the current trends. The objectives in these situations will be to institute management actions to achieve an improving trend. Downgrading the Wilderness Recreation Opportunity Class to a class more tolerant of impact will not be an option.

Over the long term, wilderness management activities should lead to an improving trend in the effects of man's activity on wilderness resources in all WROS classes.

TABLE E-2
LIMITS OF ACCEPTABLE CHANGE STANDARDS

Indicators	Pristine	Primitive	Semi-Primitive	Transition
Vegetation loss and bare, compacted mineral soil at campsites (square feet)	225	400	625	1,000
Number of Trees with roots exposed or percent (whichever is less)	0 0%	4 25%	6 25%	10 50%
Encounters--80% Probability--Maximum number of encounters per day when traveling--primary use season.	1	7	10	10-20 (Generally 10, but up to 20 on a case by case basis)
Party size-- People and stock combined.	12 (Encourage 6 or less people, 0 stock). 12 people and 18 animals in the Lake Chelan-Sawtooth Wilderness	12	12	12
Campsites visible when occupied	0	1	2	3
Dead woody debris available for firewood	Appears to be natural levels compared to adjacent similar areas.			

G. CARRYING CAPACITY

Carrying capacities have been developed to estimate the amount of recreation visitor use that a wilderness or portion of a wilderness, could support without degradation of resource values. Carrying capacity is commonly expressed in Recreation Visitor Days (RVD's) per year or people-at-one-time (PAOT).

In the Recreation Opportunity Spectrum system, coefficients have been developed that help in the estimation of carrying capacity. These coefficients are the estimated RVD's per average acre per year, that a WROS class can support. Different coefficients are identified for each class and are a theoretical estimation of capacity based on average conditions.

The Alpine Lakes Area Management Plan established the following capacity coefficients and carrying capacity in RVD's per year for the Alpine Lakes Wilderness:

TABLE E-3

WROS CLASS	RVD/ACRE/YEAR COEFFICIENT	CARRY CAPACITY RVD's PER YEAR
Trailless	0.5	169,347
Primitive	2.0	20,364
Semi-Primitive	5.0	161,210
Transition	15.0	183,630
		534,551

For the Land and Resource Management Plan for the Wenatchee National Forest, the following carrying capacity coefficients were developed in coordination with adjacent Forests sharing management of the Washington State Cascade Range Wildernesses.

TABLE E-4

WROS CLASS	RVD/ACRE/YEAR COEFFICIENT
Pristine (Dedicated Trailless)	0.25
Primitive (General Trailless)	1.00
Semi-Primitive (Trailed)	5.00
Transition	15.00

The carrying capacity for all wilderness except Alpine Lakes Wilderness, are as follows:

TABLE E-5

WILDERNESS	RVD'S/YEAR CAPACITY
Lake Chelan - Sawtooth	137,748
Glacier Peak	448,595
Goat Rocks	81,222
Henry M. Jackson	65,040
Norse Peak	60,115
William O. Douglas	267,280
Total	1,060,000 RVD'S/YEAR

The acres per WROS Class are described on page E-3

Considering the information and experienced gained in the Alpine Lakes Wilderness since implementation of the Management Plan, it is now clear, that these coefficients and the corresponding carrying capacity estimates are much too high.

With the implementation of the Limits of Acceptable Change process, carrying capacity estimates based on coefficients will no longer be necessary; although comparison may be useful.

The presence or degree of Wilderness resource deterioration will be determined through the analysis of the condition and trend of the measured changes in LAC indicators, at specific levels of visitor use. Carrying capacities determined through this process will be expressed more in terms of PAOT.

Upon completion of inventories of campsites, and baseline data is gathered on the condition of LAC indicators, more precise estimates of carrying capacity will be established for each wilderness. This analysis should be completed before any major actions are implemented to allocate use to specific individuals, or user groups, or limit visitor entry through mandatory permit systems.

Carrying capacity may be increased or reduced over time, depending on the relative degree of resource impact generated by users. It is conceivable that capacities could be increased if users become educated and generate less impact during their recreation trips in wilderness.

H. MANAGEMENT ACTIONS TO MEET MANAGEMENT OBJECTIVES

When analysis of visitor use levels and monitoring results indicate management action is necessary to solve resource impact problems, a process will be followed to select the appropriate management actions.

Areas will be field checked when inventory or monitoring data show that resource standards are being approached and the trend is downward toward greater deterioration. The field review will determine if the indicators were properly measured and if the indicators accurately reflect the resource conditions. If the measured conditions are correct, then the analysis process described in Section G will be implemented.

Tables E-6 to E-9 list a range of potential management actions depending on the specific circumstances that may be successful in reversing deteriorating conditions. The actions are listed in order of descending priority.

The emphasis in selecting management actions will focus on choosing actions which will be least intrusive to wilderness visitors, yet effective in resolving problems. In cases where problems are extensive, complex, and very visible, management actions will be required that will have some effect on visitors freedom to use certain areas.

In areas where resource impact has been severe, rehabilitation and restoration work will be accomplished to speed up the natural recovery process.

Should the management actions implemented not result in improving conditions, more restrictive and intensive management actions will be instituted. This progression will continue down through the sequence of management actions until the problems are resolved.

Management actions selected, or the extent to which an action is implemented, should also be in accord with the appropriate WROS Class of the area involved.

TABLE E-6

POTENTIAL MANAGEMENT ACTIONS TO IMPROVE CAMPSITE CONDITION
DESCENDING ORDER OF IMPLEMENTATION

Education of users outside wilderness
Information outside wilderness, at trailheads
Contact repeat users such as organized groups, clubs and associations, etc.
Wilderness Ranger contacts
Reroute trails away from lakes
Prohibit stock in campsites
Restrict camping near lakes, streams, and meadows
Prohibit campfires in specific areas
Equipment requirements
Install resource protection facilities on durable sites
Limit party group size
Limit number of stock per group
Length of stay limit in problem areas
Close campsites to specific users
Rehabilitate damaged areas
Special law enforcement efforts
Campsite closure
Campsite permits
Entry quota permit system

TABLE E-7

POTENTIAL MANAGEMENT ACTIONS TO REDUCE CAMPSITE DENSITY
DESCENDING ORDER OF IMPLEMENTATION

Education of users outside wilderness
Information outside wilderness, at trailheads
Contact repeat users such as organized groups, clubs and associations, etc.
Campsite obliteration and rehabilitation
Prohibit camping within prescribed distances of trails, lakes, streams, and meadows
Make access to problem areas more difficult
Campsite closures, may be seasonal
Closure of large areas to camping

TABLE E-8

**POTENTIAL MANAGEMENT ACTIONS TO REDUCE TRAIL
AND CAMPSITE ENCOUNTERS
DESCENDING ORDER OF IMPLEMENTATION**

Education of users outside wilderness
Information outside wilderness, at trailheads
Encourage use outside peak periods
Limit group size
Seasonal campsite closures
Restrict camping near trails
Close campsites to certain users
Close specific areas to camping
Change trailhead and access conditions
Length of stay limits
Allow only one-way travel on some trails
Campsite permits
Entry quota permit system

TABLE E-9

**POTENTIAL MANAGEMENT ACTIONS TO IMPROVE VEGETATIVE CONDITION
IMPACTED BY RECREATION STOCK AND PACK ANIMAL GRAZING
DESCENDING ORDER OF IMPLEMENTATION**

Education of users outside wilderness
Information outside wilderness, at trailheads
Allow no hay or unprocessed grain
Require use of supplemental feed
Limit total number of stock per party
Limit group size
Prohibit stock in specific areas
Prohibit stock in campsites
Eliminate facilities that are attractions
Provide facilities where impacts should be concentrated on durable sites
Allow no stock to feed within specified distance of lakes, streams, and wet areas
Seasonal Closures
Close drainages to stock on a rotating basis
Length of stay limits
Closure of large areas to stock

I. MONITORING

A wilderness monitoring program will be conducted to determine the influence of man's activity on the physical, biological, and social resources of each wilderness.

1. OBJECTIVES OF THE MONITORING PROGRAMS

- a. Determine through observation, measurement, and analysis, if man's activity, inside or outside wilderness, is resulting in change in the condition of resource values.
- b. Measure the effectiveness of management actions and programs in achieving wilderness management objectives.
- c. Provide a process for maintaining an up-to-date inventory of campsites, facilities, impacted areas, and visitor-use patterns.

2. MONITORING PROGRAM ELEMENTS

Monitoring plans for individual wilderness shall include at least the following elements:

- a. Measure the indicators of the limits of acceptable change to identify if changes in resource conditions are occurring.
- b. Observe and record general impressions of resource conditions and trends of decline or improvement.
- c. Measure or estimate the effectiveness of management actions implemented to improve or maintain resource conditions.
- d. Note and report new activities which are impacting or may lead to impact on wilderness resources.
- e. Complete or update inventories of campsites, trails, and high-use areas. Resource conditions associated with trails, such as excessive soil erosion rates, can be recorded during trail condition surveys.
- f. Gain perspective through contacts with wilderness users, if their visits to wilderness are satisfying, and if their expectations are being met.
- g. Estimate recreation visitor use.

3. MONITORING METHODS

- a. Monitoring will be conducted within the parameters described in Forest Service Handbook 2309.19, Section 21.3, Monitoring Recreation Impact.
- b. The research publication "Monitoring The Condition of Wilderness Campsites," by David N. Cole, (Research Paper INT. 302) should serve as a general guideline in monitoring the condition of campsites and heavily used areas.

4. MONITORING FREQUENCY

The frequency of monitoring actions will be described in individual management action plans for each wilderness. Frequencies should be established which will assure the attainment of wilderness monitoring objectives.

As a general rule, campsites and heavy-use areas where resource conditions approach or exceed LAC standards should be monitored at least every one to three years to establish the trends of change.

Areas of significant recreation use that are stable and are not approaching LAC indicator standards should be monitored at least every five years.

APPENDIX F

FOREST PLAN MONITORING REQUIREMENTS

A. INTRODUCTION

The monitoring approach for each major resource area is documented on one or more worksheets. The following information about the worksheets clarifies the monitoring activities associated with the resource area.

ISSUE: Numerous management issues, concerns and opportunities were identified early in the planning process. These were used to formulate, analyze, and select the preferred alternative. In order to determine how well the Forest Plan was responding to these items, certain areas of management activity were identified to receive concentrated monitoring review. These are identified under the general heading of issue area.

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: This statement should include the forest goal, desired future condition or the desired output for the issue stated on the worksheet.

MANAGEMENT AREAS AFFECTED: Many resources are addressed by management in specific management areas. This section indicates those management areas which are significant with respect to the resource at hand. Monitoring activities can generally be limited to these management areas.

RISK ASSESSMENT: This is an index of the risk involved in the resource area. The index is a function of: (1) the cost of an error which results in not meeting Forest Plan objectives and (2) the likelihood of such an error occurring. **COST OF ERROR** is estimated as "high," "moderate," or "low," depending on the value of the commodity or environmental components involved. **LIKELIHOOD OF ERROR** is estimated as "high," "moderate," or "low," depending on the level of knowledge regarding pertinent cause-effect relationships, and on the amount of pressure which is put on the resource(s) in question.

A numerical value of 1 is assigned to "low" values, 2 is assigned to "moderate" values, and 3 is assigned to "high" values. The **RISK INDEX** is the product of the **COST** and **LIKELIHOOD** values. It can range from "1" to "9." A value of "1" indicates that there is very little risk involved, and low precision, reliability, and monitoring effort is adequate. A **RISK INDEX** of "9" indicates that there is very high risk involved--therefore, high precision, reliability, and effort, are warranted.

MONITORING QUESTION: The monitoring questions are the core of the Monitoring Plan. The essence of each question is, "Are things going as the Forest Plan intended?" Information is generally included in the question to indicate that level of probability at which the question should be answered, and the variance from the target quantity which is acceptable. Information to answer these will be obtained and analyzed using value statistical procedures.

Questions are written to address varying periods of time, such as variation in annual outputs versus variation in decadal outputs. Selection of time periods and amount of variation is commensurate with the inherent variability of the resource and the risk of not meeting state objectives.

THRESHOLD OF VARIABILITY: For each monitoring question, the variation from expected outputs or activities that is permitted before corrective action or further evaluation is taken. It will be a plus or minus variation, or a phrase describing the event that will take place before further action or evaluation are initiated. The amount of variation tolerable is related to the risk involved as determined by the risk assessment.

SUGGESTED METHODS/SAMPLING PROCEDURE: For each monitoring question, methods and/or sampling procedures are suggested/directed. The purpose of this section is to suggest realistic and reasonable methods or sources of information, and it is not intended to exclude other methods as long as they will respond completely to the questions at a reasonable cost.

The sampling procedure specifies the sampling rate and sampling period for each monitoring question, as appropriate. Data will be gathered in a manner that will ensure meeting statistical parameters suggested by the monitoring questions. Suggested methods/sampling procedures are commensurate with the risk of not meeting objectives.

REPORTING PERIODS: For each monitoring question, the years in which it must be answered are indicated. A report will be prepared for each set of monitoring questions and will be summarized with all the reports due that year. Copies of this summary and the individual reports will be kept on file at the Supervisor's Office for the entire planning period. The summary will also be available to other agencies and the public.

RESPONSIBILITY: Who is responsible for accomplishing the monitoring tasks listed? The people listed here will have the assigned responsibility.

ANNUAL COST OF MONITORING: Costs are estimated and are shown as the average annual increase over current costs for all monitoring activities associated with the resource area. Although the reports are due in specific years, the data gathering and analysis work will be spread through the entire planning decade as much as possible.

FOREST PLAN MONITORING WORKSHEET

ISSUE: STANDARDS AND GUIDELINES - GENERAL

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Ensure implementation and validation of Plan standards and guidelines is effective at accomplishing Forest goals, outputs, and the desired future condition.

MANAGEMENT AREAS AFFECTED: All

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTIONS:

1. Are Forest Plan standards and guidelines being implemented?
2. Are implemented standards and guidelines achieving the expected results?

THRESHOLD OF VARIABILITY:

1. Standards and guidelines are implemented as described in the Forest Plan.
2. Same tolerances as those described for individual monitoring items on other worksheets.

SUGGESTED SAMPLING METHODS:

1. Conduct a two stage field review of at least one project/District. The 1st stage is after NEPA analysis and documentation and after project design. The 2nd stage is after project completion.
2. Compare observed findings during field review of 2nd stage with the measurements from other monitoring items described on other worksheets.

REPORT PERIOD (YEARS):

1. Annual review with a detailed report at 5 year intervals that discusses the significance of findings.
2. Documented results of annual review and discussion. A detailed report is prepared at 5-year intervals when findings from

RESPONSIBILITY: Planning Staff Officer

ANNUAL COST OF MONITORING: \$10,000 of which we are already doing \$5,000

REMARKS: NFMA states that we should monitor "how closely Management Standards have been applied." Some monitoring should be planned for all the Standards in the Plan. Monitoring will include full interdisciplinary review of the range of Management Standards. This review will determine whether the Forest Plan standards are being implemented as intended, and if implementation of these standards is meeting management area goals and objectives.

Could use this system of monitoring to identify which S&G are necessary for mitigation of the effects of activities and which are actually enhancement. Results could change funding sources for activities and be useful in preparing the TSPIRS report.

This may also meet the requirements for a "feed back" loop for the use of information from monitoring to adjust management on the ground.

FOREST PLAN MONITORING WORKSHEET

ISSUE: CHANGES IN ROS SETTINGS DUE TO MANAGEMENT ACTIVITIES INCLUDING SEMI-PRIMITIVE RECREATION SETTING

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide a well balanced array of recreation opportunities across the breadth of the Recreation Opportunity Spectrum (ROS) in accordance with public demand and expectations for outdoor recreation.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTION:

Are Forest management activities resulting in change in ROS settings so that end results do not meet the experience levels expected in the Plan?

THRESHOLD OF VARIABILITY:

Change in setting resulting in a more developed condition than that identified for a specific management area.

SUGGESTED SAMPLING METHODS:

Review randomly selected environmental documents to assure that ROS has been addressed during project design and alternative selection. Field review randomly selected areas to verify that implemented activities meet ROS standards for that area.

REPORT PERIOD (YEARS):

Annual review with a detailed report at 5 year intervals that presents a discussion of the significance of findings.

RESPONSIBILITY: District Rangers, Recreation Staff Officer

ANNUAL COST OF MONITORING: \$3,500 of which we are already doing \$1,000

REMARKS: Maintaining semi-primitive or undeveloped recreation opportunities is a Regional issue. Completion of this monitoring item can also be tied into the Forest/Management Team process for project review.

FOREST PLAN MONITORING WORKSHEET

ISSUE: FOREST TRAILS, INCLUDING OFF ROAD VEHICLE (ORV) USE

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage trail use to provide recreation opportunity in a wide range of recreation settings and in harmony with other resource management objectives.

MANAGEMENT AREAS AFFECTED: All.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTIONS:

1. Are trails providing the variety of opportunities intended in the Forest Plan?
2. Is trail use occurring without impairment of other resource values? Refer to FSM 2355.05 for definitions.
3. Are trails with mixed users (eg. horse/hiker, hiker/ORV) meeting the expectations for all intended users?

THRESHOLD OF VARIABILITY:

1. Miles of trail constructed and maintained are within 25% of the annual amount estimated in the Plan and within 10% for the decade.
2. Trail features show a stable to improving trend.
3. Comments from the public indicate an increasing trend in conflict among trail users.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1. Review of project accomplishment reports.
2. Trail condition surveys.
3. Letters and other correspondence as well as field contacts and interviews.

All. Annual review with a detailed report at 5 year intervals that presents a discussion of significant findings.

RESPONSIBILITY: District Rangers and Recreation Staff Officer

ANNUAL COST OF MONITORING: \$15,000 of which we are already doing \$7,500

REMARKS: Required by Executive Orders 11644 and 11989 for off-road vehicles.

FOREST PLAN MONITORING WORKSHEET

ISSUE: MANAGEMENT OF DEVELOPED RECREATION FACILITIES

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide safe, well maintained developed recreation facilities for public use commensurate with recreation demand.

MANAGEMENT AREAS AFFECTED: RE-1

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTIONS:

1. Are available developed recreation facilities meeting public demand?
2. Are developed recreation sites, areas and facilities being adequately maintained to serve the public and protect resource values and recreation improvements?

THRESHOLD OF VARIABILITY:

1. Use, as measured by RVDs, exceeds 60% of capacity for a site as measured by PAOTs.
2. Developed sites, acres and facilities show a declining trend in safety and resource conditions.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1. Estimate visitor use at developed recreation sites and areas.
2. Inspect recreation sites and areas.

1&2 Annually with a detailed report at 5 year intervals that discusses significance of findings. Special attention needs to be paid to use levels to adequately predict future recreation construction in time to meet demand.

RESPONSIBILITY: District Rangers, Recreation Staff Officer

ANNUAL COST OF MONITORING: \$18,000 of which we are already doing \$12,000

REMARKS: Recreation is a major use and challenge on the Wenatchee National Forest. This item is intended to provide information on use trends.

Fee collections could serve as an indicator of use trends at fee sites.

FOREST PLAN MONITORING WORKSHEET

ISSUE: MANAGEMENT OF DISPERSED RECREATION AREAS

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide opportunities for dispersed recreation activities (summer and winter) where compatible with other resource management objectives.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTIONS:

1. Are dispersed recreation sites meeting public demand?
2. Is the recreation opportunity spectrum (ROS) providing the expected variety for Forest users?

THRESHOLD OF VARIABILITY:

1. Dispersed sites show a declining trend in resource conditions.
2. Prescribed ROS classes are not met for a management area.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1. Evaluate use at dispersed sites.

1. Annually with a detailed report at 5 year intervals that discusses the significance of findings.

2. Field evaluation of a sample of projects to assure they meet desired ROS class.

2. Annually.

RESPONSIBILITY: District Ranger, Recreation Staff Officer

ANNUAL COST OF MONITORING: \$12,000 of which we are already doing \$6,000

REMARKS: Recreation is a major use of the Forest, with demand outpacing supply in some areas such as semi-primitive ROS classes.

We need better tools to assess use in dispersed areas. Code-a-site type systems could be used to track trends but they do not take into account the effects of use where sanitation facilities are not provided. *Involvement by research may be necessary.*

FOREST PLAN MONITORING WORKSHEET

ISSUE: WILD AND SCENIC RIVERS

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Retain the character and attributes of rivers recommended for wild, scenic, or recreational designation.

MANAGEMENT AREAS AFFECTED: WS-1, WS-2, WS-3

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTION:

Are resource management activities along recommended river corridors being conducted so as to provide appropriate protection at the classification level specified in the designation or study proposal?

THRESHOLD OF VARIABILITY:

When resource condition or level of activity would lower eligibility below the recommended classification.

SUGGESTED SAMPLING METHODS:

Review a sample of project analyses before and after implementation within a recommended river corridor

REPORT PERIOD (YEARS):

Annually with a detailed report at 5-year intervals that presents a discussion of the significance of findings.

RESPONSIBILITY: Recreation Staff Officer, District Ranger

ANNUAL COST OF MONITORING: \$7,000 of which we are not currently doing any since we don't have any designated rivers at this time.

REMARKS:

FOREST PLAN MONITORING WORKSHEET

ISSUE: VISUAL RESOURCE OBJECTIVES

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage vegetation and facilities to provide views that are consistent with the stated visual quality objectives for each management area. Concentrate monitoring on those management areas with visual quality objectives of partial retention or retention that also allow for changes in vegetation, especially through management of the timber resource.

MANAGEMENT AREAS AFFECTED: Forest-wide.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTIONS:

Do the cumulative effects of all resource activities within a viewshed meet the desired visual condition?

THRESHOLD OF VARIABILITY:

Desired conditions met for all areas.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

- | | |
|---|--|
| 1. Review a sample of NEPA documents for projects. Select projects from a variety of management areas. | Annually |
| 2. Field review a sample of projects representing a wide cross section of the Forest. | Annually |
| 3. Conduct a summary viewshed analysis as outlined in R-6 Supplement 65. Establish photo points for a sample of significant views and record scenes before, immediately after, and at 5 year intervals from project implementation. | Prepare a detailed report at 5-year intervals that discusses the significance of findings. |

RESPONSIBILITY: Timber & Visual Resource Management Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$14,000 of which we are already doing \$5,000

REMARKS: Needs specific data collection for the selected "piece of ground" for the integrated resource aspect in the monitoring "EVALUATION." Numbers 1 and 2 in suggested sampling methods can probably be accomplished at the same time as many other monitoring items so there should be some cost savings.

Public involvement, ID Team review, research needs in conjunction with public sensitivity.

FOREST PLAN MONITORING WORKSHEET

ISSUE: RECREATION IMPACTS ON WILDERNESS RESOURCE

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage Wilderness to perpetuate wilderness character, natural ecological processes and to provide recreation opportunities appropriate in Wilderness.

MANAGEMENT AREAS AFFECTED: All Wilderness.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 3 = RISK INDEX 6

MONITORING QUESTIONS:

Is recreation visitor use or management resulting in change in physical, biological or social settings that approach limit of acceptable change (LAC) standards specified in the Forest Plan?

THRESHOLD OF VARIABILITY:

1. When the desired biological or physical settings are within 90% of the LAC standard
2. When the amount of dead woody debris around campsites is observed at less than a natural level.
3. When annual visitor use of an area approaches 95% of the established carrying capacity for that WROS class.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1&2 Evaluate indicators of LAC through measurement of impacts, campsite condition class estimation, observation of resource conditions and established photo points.

Annually with a detailed report at 5-year intervals that describes the significance of findings.

2. Estimate visitor use through registration, permits, wilderness ranger counts, surveys and photo - electric counts.

RESPONSIBILITY: District Rangers and Recreation Staff Officer

ANNUAL COST OF MONITORING: \$33,000 of which we are already doing \$10,000

REMARKS: This item addresses the policy of nondegradation (FSM 2320.3) and complies with 36 CFR 293 related to maximum levels of use.

The 90% figure for LAC standard means that we are willing to accept a specific amount of change at a setting but we want to know conditions before we get to that point. For example, we may be willing to accept up to 100 square feet of impacted area at a popular Wilderness destination. The 90% limit would mean that we need to start acting when the amount of impact reaches 90 square feet.

FOREST PLAN MONITORING WORKSHEET

ISSUE: CULTURAL AND HISTORICAL SITE PROTECTION

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: To the extent practical, protect cultural and historical resources from vandalism, disturbance from project activities, and natural degradation.

MANAGEMENT AREAS AFFECTED: Forest-wide.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTIONS:

1. Are the National Register characteristics of unevaluated and significant cultural resource properties being protected?
2. Are all reasonably locatable cultural resources being discovered during project area reconnaissance?

THRESHOLD OF VARIABILITY:

1. Significant characteristics are being protected on at least 90% of the cultural resource properties inspected.
2. Discovery of a significant cultural resource during project implementation.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

- | | |
|--|----------|
| 1. Field inspect all significant sites in active project areas. Visit all sites in areas where people, animals, and the environment are likely to cause losses or degradation. | Annually |
| 2. Conduct surveys of all high probability areas on 20% of active projects during ground disturbing activity. | Ongoing |

RESPONSIBILITY: Recreation Staff Officer and District Rangers

ANNUAL COST OF MONITORING: \$10,000 of which we are already doing \$3,000

REMARKS:

FOREST PLAN MONITORING WORKSHEET

ISSUE: CULTURAL AND HISTORICAL SITE REHABILITATION

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Rehabilitate damaged sites eligible for inclusion in the National Register of Historic Places.

MANAGEMENT AREAS AFFECTED: Forest-wide.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTION:

For sites eligible for inclusion in the National Register of Historic Places, is appropriate stabilization or rehabilitation of damage being completed?

THRESHOLD OF VARIABILITY:

Significant sites are being degraded by vandalism, project activity, and/or the environment.

SUGGESTED SAMPLING METHODS: REPORT PERIOD (YEARS):

Review all reports on the condition Annually
of significant sites and measures
taken to repair damage.

RESPONSIBILITY: Recreation Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$3,750; we are not currently doing any of this

REMARKS:

FOREST PLAN MONITORING WORKSHEET

ISSUE: COORDINATION AND COMMUNICATION OF FOREST PROGRAMS WITH INDIAN TRIBES.

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Coordinate with appropriate Tribal representatives for all projects in which Indians may have concerns.

MANAGEMENT AREAS AFFECTED: Forest-wide.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

Failure to coordinate appropriate projects with Tribal representatives could result in lawsuits or court injunctions. Failure may also indicate noncompliance with NFMA, ARPA or AIRFA requirements or infringement on Treaty rights.

MONITORING QUESTIONS:

1. Are American Indian rights being protected on National Forest lands?
2. Are projects with activities or areas of concern to Indians being coordinated with appropriate Tribal representatives?

THRESHOLD OF VARIABILITY:

1. All rights are protected by treaty.
2. Same thresholds as for specific resource items of concern to tribes.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

- | | |
|---|---|
| 1. Review a sample of NEPA documents for projects in areas of concern to Indians. | 1&2. Annually with a detailed report at 5-year intervals that describes the significance of findings. |
| 2. Evaluate resource output levels for fish, wildlife, and other resources of concern to Indians. | |

RESPONSIBILITY: District Rangers, Planning Staff Officer, and Staff Officer for Cultural Resources.

ANNUAL COST OF MONITORING: \$15,000 of which we are already doing \$5,000

REMARKS: Examples of religious resources or resources covered by Treaty rights are fish, wildlife and certain plants. Examples of appropriate projects requiring review are trail or campground construction, wildlife and fish habitat improvements, timber harvest, road construction, or range improvements.

FOREST PLAN MONITORING WORKSHEET

ISSUE: MAINTENANCE OF SENSITIVE PLANT POPULATIONS

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide appropriate habitat to maintain viable populations or enhance populations of all threatened, endangered, and sensitive plant species.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

Cost of error is high because although only small areas would be affected at one time, some populations are very limited and error could result in a species being Federally listed. Likelihood of error is moderate because much information on occurrence and habitat requirements still needs to be gathered.

MONITORING QUESTION:

Are sensitive plant species populations being maintained or increasing?

THRESHOLD OF VARIABILITY:

Ten percent decline in the size of a population at a monitoring site for non-category plants, 5% decline for Category 1 or 2 plant populations.

SUGGESTED SAMPLING METHODS:

// A sample of plant populations will be monitored long-term; all category 1 & 2 populations plus about 50 plots for other sensitive species. Selected locations will be monitored to determine trends.

REPORT PERIOD (YEARS):

All activities will include an inventory for sensitive plants as part of NEPA process. Monitoring of specific populations will be completed during and immediately after activity. Populations not affected by proposed activity will be monitored at 5 year intervals to determine changes and trends.

RESPONSIBILITY: District Rangers are responsible for District monitoring, Forest Staff coordinates sampling methods, selects monitor sites, compiles data, and produces Forest report.

ANNUAL COST OF MONITORING: \$5,500 first 5 years \$4,800 second 5 years

We are currently doing about \$4,000 of this.

See REMARKS for details on costs.

REMARKS:

Costs for monitoring 50 permanent plots - ten per year. During the first visit to a site (first five years of LRMP) permanent plots will need to be set up, which will require 1 day of field work and 1/2 day office work per site, or 1.5 days x 10 sites x 2 people (2 @ GS-7) x \$100 per day = \$3,000. For first visits to establish plots, 5 days of a journeyman botanist or ecologist (GS-11/12) will be required for all sites or 5 days x \$150 per day = \$750; for a total of \$3,750. During Subsequent visits to a site (after first five years of Plan), 1 site can be monitored per day including office work, or 1 day x 10 sites x 2 people x \$100 per day = \$2,000. After the second-visit regime begins in the sixth year, we expect one site per year to drop below the 20 percent threshold, the subsequent management review will cost \$1,000. Each year the journeyman botanist/ecologist (GS-11/12) will need to spend three days analyzing data and preparing a report.

$$\text{First 5 years: } \frac{\$3,750 + \$0 + \$450}{(\text{Field Surveys}) + (\text{Review}) + (\text{Compilation/report})} = \$4,200 \text{ (Annual Cost)}$$

$$\text{Thereafter: } \frac{\$2,000 + \$1,000 + \$450}{(\text{Field Surveys}) + (\text{Review}) + (\text{Compilation/report})} = \$3,500 \text{ (Annual Cost)}$$

For monitoring, one-fifth of the selected plots will be evaluated annually. Selection of plant species for sampling will be done in coordination with the Washington Natural Heritage Program. 2 or 3 species at one location counts as 1 site and sites for sampling should cover a number of types of habitat and substrate (e.g. bogs, moist forest, rocky places; granitics, serpentine, basaltic etc.). Where possible, sites selected will be those with the most potential for resource conflicts (timber harvesting, road building, mining, recreation, or areas where unauthorized digging of sensitive plants may occur). If possible, those plants with the fewest known extant populations should receive priority in the sample plots. Each species sampled should have representation from at least two areas (if two areas are known). For a list of the sensitive species see Chapter IV of the Forest Plan.

Permanent photo plots or transects should be set up at all sites. Each site will be monitored every fifth year. Small populations will be individually counted, plant numbers in large populations will be estimated systematically. (Regional Ecologist's techniques for photo plots should be used; consult Forest/Area Ecologist).

Coordinate work on federal candidate species with the USDI Fish and Wildlife Service. Coordinate work on sensitive species with the Washington State Department of Natural Resources-Washington Natural Heritage Program. Coordinate research needs with the appropriate universities and colleges.

At this time the plant species for which this monitoring plan was created include:

- Delphinium viridescens;
- Hackelia venusta;
- Petrophytum cinerascens,
- Sidalcea oregana var. calva; and
- Silene seelyi.

FOREST PLAN MONITORING WORKSHEET

ISSUE: BIODIVERSITY.

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain native and desirable introduced or historic plant and animal species and communities. Provide all seral stages of all plant associations in a distribution and abundance to assure species diversity and viability. A desired future condition is to establish the local needs of management indicator species, rare species, and the proportion of seral stages that allows for natural diversity.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTIONS:

1. Is the trend of biological diversity moving as estimated?

2. Is the model for biological diversity being used on project and sub-drainage evaluations?

THRESHOLD OF VARIABILITY:

There are no established thresholds for biodiversity on the Forest. Thresholds and requirements of individual species (i.e., fish, woodpeckers, spotted owl) have been established and are being monitored as described in other items. Management direction has been set in some cases such as for fish habitat improvement, meadow maintenance and enhancement, and maintenance of early seral stages for wildlife forage and cover. As we accumulate information, sub-drainages may be used to evaluate the trends in biodiversity.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1. Assess biological diversity using the diversity index.

Annually with a detailed report at 5 year intervals that presents a discussion on the significance of findings.

2. Review 20% of NEPA documents to assure compliance with required assessment of biological diversity on a project and sub-drainage basis.

Annually.

RESPONSIBILITY: Range, Wildlife, Fish, Water, Soil Staff Officer.

ANNUAL COST OF MONITORING: \$3,000 We are not yet doing any of this.

REMARKS: This item is a real unknown. We have not done this kind of monitoring in the past. Most of our evaluations have been based on professional judgement without hard data. We really don't have an index yet but we need to respond to the growing public concern with diversity. Development of an index would be an excellent research opportunity.

The questions and sampling methods discussed above generally refer to monitoring not research. Some of the discussion below refers more to research.

Biodiversity touches many planning issues. Issues related to forest structure distribution over time such as the amount and distribution of old-growth forest, the conversion of hardwood-dominated stands to conifer dominated stands, the amount and rate of timber harvested; the amount, quality, and distribution of animal habitat; and the structure of our streams potentially affect biodiversity. Other issues are more commonly related to species composition concerns. Sensitive plant and animal species, management indicator species, and species diversity are examples. Issues such as long-term forest productivity, management of logging residues, species viability, and forest fragmentation, on the other hand relate to the functions of the forest as an ecosystem. Most of these issues are covered by specific monitoring plans.

Some methods to assess attributes that are integral parts of diversity are enumerated below:

1. Use the resource inventory to determine plant association and seral stage and assess the presence/absence of selected common wildlife species.
2. Use stake tree plots, stand exams, silvicultural visits, unit exams, and ecoplots to map plant associations and existing seral stages. These exams are ongoing and used to update data bases. With the installment of the GIS system the process will be streamlined and can be efficiently used to display distribution of seral stages. The Forest wildlife biologist, ecologist, silviculturist, and botanist will be responsible parties.
3. The Forest botanist will use rare plant surveys and monitoring data to evaluate population abundance and trends in density.
4. Information combined from the above sources on species abundance and distribution will be used by the Forest wildlife biologist and Forest/Area ecologist to evaluate the trends in species richness and evenness.

FOREST PLAN MONITORING WORKSHEET

ISSUE: OLD GROWTH ECOSYSTEMS

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain old growth forest ecosystems as needed for plant habitat, esthetics and biological diversity while still providing appropriate levels of timber for commodity use.

MANAGEMENT AREAS AFFECTED: All areas where old growth occurs.

RISK ASSESSMENT: $COST\ OF\ ERROR\ 3 \times LIKELIHOOD\ OF\ ERROR\ 1 = RISK\ INDEX\ 3$

MONITORING QUESTION:

Is old growth acreage being retained at the expected rate?

THRESHOLD OF VARIABILITY:

Acreage meeting the definition of old growth as identified in the Forest Plan, varies more than 10% from predicted acres.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

Amounts and locations of Old Growth stands are inventoried and changes recorded in appropriate geographic data base (GIS), periodic timber sale accomplishment report (PSTAR) and in the STARS data base.

Detailed report at 5-year intervals that discusses the significance of findings.

RESPONSIBILITY: District Rangers, and Timber & Visual Resource Management Staff and Range, Wildlife, Fish, Soil and Water Staff Officer.

ANNUAL COST OF MONITORING: \$10,000 of which we are already doing \$3,000

REMARKS: Monitoring needs for Old Growth and Mature wildlife indicator species are included in separate monitoring worksheets. Additional research is needed on a variety of old growth ecosystems and related attributes (See information needs section Chapter II).

FOREST PLAN MONITORING WORKSHEET

ISSUE: NORTHERN SPOTTED OWL (Old Growth and Mature Indicator)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide habitat to maintain viable populations for all vertebrate species on the Forest. Maintain spotted owl habitat capability to provide for no less than 116 pairs of spotted owls at the end of the first decade.

MANAGEMENT AREAS AFFECTED: Where suitable spotted owl habitat is found.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 3 = RISK INDEX 9

Cost of error is high because network has a number of large areas without habitat that cause weaknesses. Likelihood of error is high because of lack of information of Spotted Owl use of grand fir type and winter range.

MONITORING QUESTIONS:

1. Is sufficient habitat capability being maintained to meet 1st decade goal?
2. Are network sites occupied by spotted owls at expected rates?

THRESHOLD OF VARIABILITY:

1. Forest total is within 15% of the estimated amount of suitable habitat.
2. Trend for occupancy is stable to increasing.

SUGGESTED SAMPLING METHODS:

1. Use GIS to track suitable habitat.
2. Regional protocol for spotted owl monitoring

REPORT PERIOD (YEARS):

Annually with a detailed report at 5-year intervals that presents a discussion of the significance of findings.

RESPONSIBILITY: District Rangers, Range, Wildlife, Fish, Water and Soil Staff Officer.

ANNUAL COST OF MONITORING: 1. \$4000 of which we are already doing \$3,000
2. \$85,000 all of which we are currently doing

REMARKS:

1. Cooperative research with WDW and PNW on use of grand fir habitat and winter habitat.
2. Demographic study in cooperation with WDW and PNW.
3. Prey base study in cooperation with WDW and PNW.
4. Research silvicultural treatments to create, maintain and/or enhance spotted owl Habitat in cooperation with WDW, PNW and NCASI.

FOREST PLAN MONITORING WORKSHEET

ISSUE: PILEATED WOODPECKER HABITAT (Old Growth and Mature Indicator)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide habitat to maintain viable populations for all vertebrate species on the Forest including habitat effectiveness for at least 50 pileated woodpeckers sites identified in the Forest Plan. (These are in addition to habitat available in SOHAs, Wilderness, areas to remain undeveloped, and other areas to be left in a near natural condition.)

MANAGEMENT AREAS AFFECTED: Identified pileated woodpecker habitat areas.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

Cost of error is moderate because there are replacement acres where a lost area may be relocated. Likelihood of error is moderate because no harvest will be done in minimum area this decade. Wildfire may eliminate some of the sites.

MONITORING QUESTIONS:

1. Are the number of areas identified in the plan being maintained?
2. Are the established sites being used by pileated woodpeckers?

THRESHOLD OF VARIABILITY:

1. 100% of the MR sites and 80% of additional sites are being maintained as planned.
2. 20% occupancy of established sites.

SUGGESTED SAMPLING METHODS:

1. Review all sites that had other resource management activities occurring.
2. Visit at least 10% of sites.

REPORT PERIOD (YEARS):

Annually with a detailed report at 5-year intervals that presents a discussion on the significance of findings.

RESPONSIBILITY: District Rangers, Range, Wildlife, Fish, Water and Soil Staff Officer.

ANNUAL COST OF MONITORING: \$4,500 We are not yet doing any of this.

REMARKS:

1. Need research on habitat requirements (in cooperation with WDW & PNW).
2. Need to document habitat requirements of species represented by the pileated woodpecker in cooperation with WDW & PNW.
3. Need to inventory population of pileated woodpecker (in cooperation with WDW).
4. Need to map suitable habitat.
5. Develop model for predicting effects on habitat (coop with WDW and PNW).

FOREST PLAN MONITORING WORKSHEET

ISSUE: MARTEN AND NORTHERN 3-TOED WOODPECKER (Old Growth and Mature Indicator)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide habitat to maintain viable populations for all vertebrate species on the Forest and maintain habitat effectiveness of 150 marten and northern 3-toed woodpecker sites. (These are in addition to habitat available in SOHAs, pileated woodpecker areas, Wilderness, and other areas to be retained in a near natural condition.)

MANAGEMENT AREAS AFFECTED: Identified marten and northern 3-toed woodpecker habitat areas.

RISK ASSESSMENT: COST OF ERROR 2 LIKELIHOOD OF ERROR 2 = RISK INDEX 4

Cost of error is moderate because there are other places where the lost sites may be moved. Likelihood of error is moderate because no harvest will be done in minimum areas this decade. Wildfire may eliminate some of the sites.

MONITORING QUESTIONS:

1. Are the areas identified in the plan being maintained?
2. Are the established sites being used by marten and northern 3-toed woodpeckers?

THRESHOLD OF VARIABILITY:

1. 100% of MR and 80% of all other sites are being maintained.
2. A minimum occupancy of 20% is achieved.

SUGGESTED SAMPLING METHODS:

1. Review all sites that had other resource management activities occurring.
2. Visit at least 10% of sites.

REPORT PERIOD (YEARS):

Annually with a detailed report at 5-year intervals that presents a the significance of findings.

RESPONSIBILITY: District Rangers, Range, Wildlife, Fish, Water and Soil Staff Officer.

ANNUAL COST OF MONITORING: \$10,600 We are not yet doing any of this.

REMARKS:

We have the same research and inventory needs for these indicator species as we listed for the Pileated Woodpecker.

FOREST PLAN MONITORING WORKSHEET

ISSUE: MOUNTAIN GOAT HABITAT (Indicator species for high elevation and talus)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain or increase populations. Provide animals for recreation enjoyment. Outputs: Estimate 1,800.

MANAGEMENT AREAS AFFECTED: Where mountain goat habitat is found.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 1 = RISK INDEX 3

Cost of error is high due to high demand for hunting and viewing and the small population. Chance of error is low because most of our habitat is in management areas with direction compatible with goat habitat objectives.

MONITORING QUESTION:

Is each subpopulation being maintained or increasing?

THRESHOLD OF VARIABILITY:

No downward trend.

SUGGESTED SAMPLING METHODS:

Use State estimates.

REPORT PERIOD (YEARS):

Annually with a detailed report at 5-year intervals the presents the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soil Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$2,000 of which we are already doing \$1,000

REMARKS:

1. Prepare a Forest-wide Species Management Guide (including specific items for each sub-population) in cooperation with WDW.
2. Map suitable habitat and key areas in cooperation with WDW.
3. Develop model for predicting HSI in cooperation with WDW and PNW.

FOREST PLAN MONITORING WORKSHEET

ISSUE: DEER AND ELK HABITAT (Forest Indicator Species)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain habitat capability to support populations identified in the Forest Plan and provide animals for recreation enjoyment. Outputs (in summer range): Elk 10,000 -15,000; Deer 20,000 -25,000.

MANAGEMENT AREAS AFFECTED: All management areas with identified habitat.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

Cost of error is moderate because of the demand for big game and the tradeoffs of this resource to manage. The likelihood of error is moderate because of some uncertainty of the quantity of thermal cover and identification of winter range used by big game.

MONITORING QUESTIONS:

1. Are populations being maintained as predicted?
2. Is habitat capability being maintained?

THRESHOLD OF VARIABILITY:

1. Population estimates are at least 80% of projections for any five year period.
2. Forage/cover ratios are within 20% of optimum for any subdrainage.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

- | | |
|---|----------------------|
| 1. State agency census records. | At 5-year intervals. |
| 2. Habitat relationship modeling for projects affecting habitat capability. | As projects occur. |

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soil Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$6,000 We are not yet doing any of this.

REMARKS:

1. Prepare species management guides for each winter range in cooperation with WDW.
2. Develop model for predicting HSI in cooperation with WDW and PNW.
3. Map suitable habitat by type.
4. Cooperate with WDW on road closure areas and habitat improvement

FOREST PLAN MONITORING WORKSHEET

ISSUE: **PRIMARY CAVITY EXCAVATORS (Indicator Species Group for dead/defective trees)**

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide habitat to maintain viable populations. Maintain number, size and distribution of trees and snags to meet habitat capability objective by management area as shown in the Forest Plan and provide animals for recreation enjoyment Outputs: at least 40% of the theoretical population Forest-wide.

MANAGEMENT AREAS AFFECTED: All forested management areas

RISK ASSESSMENT: $\text{COST OF ERROR}_2 \times \text{LIKELIHOOD OF ERROR}_2 = \text{RISK INDEX}_4$

Cost of error is moderate because most trees needed by wildlife are soft snags and it takes 10-30 years to replace; however, we have many management areas with an abundance of habitat. Likelihood of error is moderate because we have problems with coordination of salvage and green tree projects, fuelwood gathering and State safety requirements.

MONITORING QUESTIONS:

1. Are primary cavity excavator habitat and replacement trees being left in the proper numbers, sizes and distribution within each management area?
2. Is the habitat being utilized as expected?
3. Are down trees being provided?

THRESHOLD OF VARIABILITY:

1. Habitat availability is nearing the amount specified for a management area.
2. Evidence of use is less than 50% of expected.
3. No downward trend in amount available.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1. Field review of at least 2 completed projects/District/year.
2. Use transects to estimate use level on a subdrainage basis. Sample 10% of subdrainages in which tree removal occurred.
3. Establish transects to measure amount of down material as in number 2.

Annually with a report on trend at 5-year intervals.

RESPONSIBILITY: District Rangers, Range, Wildlife, Fish, Water, and Soil Staff Officer.

ANNUAL COST OF MONITORING: \$10,000 of which we are already doing about \$3,000

1.Can be combined with the management team review described on the Standards and Guidelines Worksheet but some field measurements will be needed prior to review.

REMARKS:

1. Prepare a Species Management Guide in cooperation with WDW.
2. Document the habitat requirements of all species represented by primary cavity excavators in cooperation with WDW and PNW.
3. Need estimates of populations in near natural conditions.
4. Develop model for predicting Habitat Suitability Index in cooperation with WDW and PNW.
5. Map the Suitable Habitat.

The standard in the Forest Plan is designed to meet Regional direction on a per 40 acre basis.

FOREST PLAN MONITORING WORKSHEET

ISSUE: HAWK AND OWL NEST SITES

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain viable populations and provide animals for recreation enjoyment.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

Cost of error is moderate. Demand for viewing is high. Populations are high and healthy. These species often have high values for falconry. We must meet the requirements of the Migratory Bird Treaty Act. Likelihood of error is also moderate. It is unlikely that we will ever find all hawk and owl nests.

MONITORING QUESTION:

Are nest sites being protected during implementation of habitat disturbing activity?

THRESHOLD OF VARIABILITY:

Previously unknown nests are disturbed during project implementation.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

Timber sale administrators and project CORs watch for nests during project implementation.

As projects occur. A detailed report be prepared at 5-year intervals to evaluate trend.

RESPONSIBILITY: District Ranger, Range, Wildlife, Fish, Water and Soil Staff Officer.

ANNUAL COST OF MONITORING: \$2,000 of which we are already doing \$1,000

There will be incidental annual administrative costs for monitoring but most of the cost is for the 5-year report.

REMARKS:

Information needs include:

1. List species of concern. (WDW)
2. Nesting requirements of each species. (WDW)
3. A useable map of sighting of all species. (WDW)
4. Feeding habitat requirements by each species. (WDW)
5. Species management Guide. (WDW)

FOREST PLAN MONITORING WORKSHEET

ISSUE: **BALD EAGLE HABITAT (T.E.&S. Wildlife)**

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage critical habitat to improve status of threatened and endangered species to a point where they no longer need protection under the Endangered Species Act. Meet recovery levels established in the Pacific States Bald Eagle Recovery Plan.

MANAGEMENT AREAS AFFECTED: Management areas with active and potential nest sites, roost sites and perches.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

Cost of error is high because we have so few active nest sites. Likelihood of error is moderate because we have not located all nest, roost and perch sites.

MONITORING QUESTIONS:

1. Are existing nest sites producing young as anticipated?
2. Are nest, roost and perch sites being maintained?

THRESHOLD OF VARIABILITY:

1. No active site is unused for two successive seasons.
2. All managed sites are maintained until Forest has achieved recovery goal.

SUGGESTED SAMPLING METHODS:

1. Interagency survey of nest sites.
2. Review designated sites.

REPORT PERIOD (YEARS):

Annually with a detailed report at 5-year intervals that presents the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soil Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$5,000 of which we are already doing \$3,000

REMARKS:

1. Nest site surveys coordinated with WDW.
2. Locate roosts and perches with WDW.
3. Map of suitable habitat.
4. Model for predicting habitat effectiveness in cooperation with WDW.
5. Develop a Species Management Guide in cooperation with WDW and US FWL.

FOREST PLAN MONITORING WORKSHEET

ISSUE: GRIZZLY BEAR (Threatened Species)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage critical habitat to improve the status of threatened and endangered species to a point where they no longer need protection under the Endangered Species Act.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR₃ X LIKELIHOOD OF ERROR₁ = RISK INDEX₃

Cost of error is high because of extremely low populations. Likelihood of error is low because of an ongoing process to identify habitat.

MONITORING QUESTION:

Are guidelines established for the North Cascades Grizzly Bear Recovery Area being implemented?

THRESHOLD OF VARIABILITY:

Projects are found that do not comply with guidelines.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

Review 20 percent of NEPA documents and follow up with field verification on 1 or 2 projects/District/year.

Annually

RESPONSIBILITY: District Rangers, Range, Wildlife, Fish, Water and Soil Staff Officer.

ANNUAL COST OF MONITORING: \$1,000 We are currently operating at this level.

REMARKS:

1. Continue habitat inventory.
2. Continue documentation of bear sightings. (WDW)
3. Respond to Recovery Plan when completed. (USFWS, WDW)

FOREST PLAN MONITORING WORKSHEET

ISSUE: PEREGRINE FALCON HABITAT (T.E.&S. Wildlife)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage critical habitat to improve status of threatened and endangered species to a point where they no longer need protection under Endangered Species Act. Cooperate in development of the recovery plan. Outputs: 1 - 2 active nests.

MANAGEMENT AREAS AFFECTED: Areas where habitat is found.

RISK ASSESSMENT: $\text{COST OF ERROR}_3 \times \text{LIKELIHOOD OF ERROR}_3 = \text{RISK INDEX}_9$

Cost of error is high because we have a threatened species with no identified sites on Forest. Cost of error is high because we have few inventories of habitat and may inadvertently make errors.

MONITORING QUESTIONS:

1. Are recovery sites being maintained?
2. Are sites occupied?

THRESHOLD OF VARIABILITY:

1. All recovery sites are maintained.
2. Occupancy of Wenatchee National Forest sites is equal to other recovery sites east of the Cascade crest.

SUGGESTED SAMPLING METHODS:

1. Review condition of recovery sites.
2. Survey sites for occupancy.

REPORT PERIOD (YEARS):

Annually with a detailed report at 5-year intervals that presents the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soil Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$3,000 of which we are doing \$500

REMARKS:

1. Prepare a Species Management Guide in cooperation with WDW.
2. Complete Nesting Habitat Survey in cooperation with WDW.
3. Map suitable habitat.
4. Develop a HSI model in cooperation with WDW.

FOREST PLAN MONITORING WORKSHEET

ISSUE: GRAY WOLF HABITAT (Endangered Species)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage critical habitat to improve the status of threatened and endangered species to a point where they no longer need protection under the Endangered Species Act. Participate in the development of recovery plan objectives.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 3 = RISK INDEX 9

Cost of error is high because populations are low. Likelihood of error is high because we have no inventories of habitat.

MONITORING QUESTIONS:

Is habitat capability on an increasing trend?

THRESHOLD OF VARIABILITY:

A downward trend.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

Map habitat and track changes through GIS.

Annually with a report at 5-year intervals to establish a trend in habitat capability.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soil Staff Officer: District Rangers.

ANNUAL COST OF MONITORING: \$1,000 We are not doing any of this.

REMARKS:

1. Research on habitat requirements (PNW, WDW)
2. Map of habitat (WDW)
3. Inventory population (WDW)
4. Prepare Species Management Guide (WDW)
5. Prepare model for predicting HSI (WDW, PNW)

FOREST PLAN MONITORING WORKSHEET

ISSUE: HABITAT FOR SPECIES IDENTIFIED AS CANDIDATES FOR THREATENED STATUS

(California wolverine, Swainson's and ferruginous hawks, lynx, long-billed curlew, Townsend's big eared bat, big horned sheep)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Enhance habitat to prevent the need for listing species as Federally Threatened or Endangered.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR₃ X LIKELIHOOD OF ERROR₃ = RISK INDEX₉

Cost of error is high because we have low populations. Likelihood of error is high because we have no research, no specific direction, no inventories of populations or habitat. We have little or no experience managing habitat.

MONITORING QUESTIONS:

Is the trend in habitat capability for each candidate species increasing?

THRESHOLD OF VARIABILITY:

A declining trend.

SUGGESTED SAMPLING METHODS:

Map changes in habitat through GIS.

REPORT PERIOD (YEARS):

Annually with reports at 5-year intervals that describe the trend.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soil Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$6,000 We are not doing any of this.

Most of the cost will be in development of the report for each species.

REMARKS:

1. Research on habitat requirements (PNW, WDW)
2. Map of habitat (WDW)
3. Inventory population (WDW)
4. Prepare Species Management Guide (WDW)
5. Prepare model for predicting HSI (WDW, PNW)

FOREST PLAN MONITORING WORKSHEET

ISSUE: TIMBER OFFERED (Allowable Sale Quantity [ASQ] and Timber Sale Program Quantity [TSPQ])

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Achieve planned and assumed volumes of timber sold annually and for the planning period in ASQ and TSPQ.

MANAGEMENT AREAS AFFECTED: For ASQ, all volumes from Management Areas with suitable lands. For TSPQ, all Management Areas where timber harvest is allowed to meet any resource objective.

RISK ASSESSMENT: $\text{COST OF ERROR}_2 \times \text{LIKELIHOOD OF ERROR}_1 = \text{RISK INDEX}_2$

MONITORING QUESTIONS:

1. Is the Forest offering the cubic foot volume (board feet in first decade) of chargeable timber established by the plan ASQ?
2. Is the Forest offering the cubic foot volume (board feet in first decade) of non-chargeable timber necessary to achieve the estimated TSPQ?

THRESHOLD OF VARIABILITY:

The annual amount of timber offered is within 25% of scheduled ASQ and TSPQ. The decade total is within 5% of the Forest Plan projection.

SUGGESTED SAMPLING METHODS:

Use STARS data base and compare volume in MCF to projected decade trend.

REPORT PERIOD (YEARS):

Annually with a report at years 5 and 8 of each decade. Adjustments to timber sale schedule made at these times if necessary.

RESPONSIBILITY: Timber & Visual Resource Management Staff Officer, District Rangers.

ANNUAL COST OF MONITORING: \$3,500 We are currently doing all of this.

REMARKS: To assure decade ASQ not exceeded. To test Plan assumption regarding TSPQ.

Need to have an accurate method to convert board feet to cubic feet or a system which allows accurate cubic foot cruising.

For meeting Plan amounts, we can monitor on a board foot basis during the first decade but we still need to get serious about converting our measurements to cubic feet.

FOREST PLAN MONITORING WORKSHEET

ISSUE: TIMBER HARVEST UNITS (Size, shape and location)

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage vegetative cover to meet direction on size of openings created by National Forest timber harvest.

MANAGEMENT AREAS AFFECTED: All Management Areas where scheduled or non-scheduled timber harvest can occur.

RISK ASSESSMENT: $\text{COST OF ERROR}_2 \times \text{LIKELIHOOD OF ERROR}_1 = \text{RISK INDEX}_2$

MONITORING QUESTION:

Are the Forest Plan standards and guidelines regarding the size and dispersal of openings and condition of adjacent vegetation (eg. height of trees in adjacent areas) being appropriately implemented?

THRESHOLD OF VARIABILITY:

No allowance for non conformance with size restrictions that do not fit exceptions provided by NFMA and the Regional Guide. At least 90% of activities must fully meet shaping and blending objectives

SUGGESTED SAMPLING METHODS:

Review of a sample of created openings in the field.

REPORT PERIOD (YEARS):

Annual review of created openings with a report at 5 year intervals that presents a discussion of the significance of findings.

RESPONSIBILITY: District Ranger, Timber & Visual Resource Management Staff Officer

ANNUAL COST OF MONITORING: \$5,000 of which we are doing \$4,000

REMARKS:

FOREST PLAN MONITORING WORKSHEET

ISSUE: TIMBER HARVEST

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Ensure that regeneration harvests are not prescribed for areas where average annual growth has not generally reached culmination of mean annual increment.

MANAGEMENT AREAS AFFECTED: All areas where timber harvest is expected.

RISK ASSESSMENT: $\text{COST OF ERROR}_2 \times \text{LIKELIHOOD OF ERROR}_2 = \text{RISK INDEX}_4$

MONITORING QUESTIONS:

1. Are stands being harvested at an age and condition that produces the expected growth measured on an average annual cubic foot basis?
2. Is the amount of volume removed consistent with amounts sold?

THRESHOLD OF VARIABILITY:

1. Stands being scheduled for regeneration are within 5% of culmination of mean annual increment.
2. Volume removed is within 10% of amount sold.

SUGGESTED SAMPLING METHODS:

1. Review a sample of silvicultural harvest prescriptions calling for regeneration.
2. Cut and sold reports.

REPORT PERIOD (YEARS):

Annual comparison and a report at 5-year intervals that presents a discussion of the significance of findings.

RESPONSIBILITY: District Rangers and Timber & Visual Resource Management Staff Officer.

ANNUAL COST OF MONITORING: \$12,000 of which we are doing \$6,000

REMARKS: Question 1 is intended to tie prescriptions to CMAI. Needs to be monitored because yield tables and rotations in long-term yield calculations are based on harvesting stands at or near CMAI. Question 2 added to provide better tie between timber offered/sold and timber harvested. Question becomes less significant as we move toward sales with payment units or implement a timber management program based on acre controls.

FOREST PLAN MONITORING WORKSHEET

ISSUE: SILVICULTURAL PRACTICES

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Assure that silvicultural prescriptions are appropriate, effective and consistent with resource objectives for each management area.

MANAGEMENT AREAS AFFECTED: All Management Areas where scheduled or non-scheduled timber harvest can occur.

RISK ASSESSMENT: $COST\ OF\ ERROR_2 \times LIKELIHOOD\ OF\ ERROR_3 = RISK\ INDEX_6$

MONITORING QUESTIONS:

1. How many acres of each planned silvicultural practice (eg. precommercial thinnings, regeneration harvest, planting with appropriate genetic stock) have been accomplished?
2. Have silvicultural prescriptions met objectives desired for each management area?
3. Are managed stands growing at the rates estimated by Forest Plan yield models (PROGNOSIS)?

THRESHOLD OF VARIABILITY:

1. Planned versus accomplished silvicultural practices are within 10% annually and 5% for the decade.
2. Prescriptions produce desired end products on at least 90% of treated acres.
3. Average annual growth is within 10% of predicted rates.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1 & 2. Field exams for attainment purposes. Use the SILVA, TSI and Reforestation attainment data element within the TRACS data base.

Make annual field exams and comparisons, with a full report at 5 year intervals that presents a discussion of the significance of findings.

3. Modified stand exams in sapling stands and at regular intervals thereafter.

First measurement when trees reach sapling size. Report presenting findings will be prepared at year 8 of the first decade and at 10-year intervals thereafter.

RESPONSIBILITY: Timber & Visual Resource Management Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$20,000 of which we are doing \$6,000

REMARKS: Needed for Plan implementation and support of ASQ. Long-term need to verify that projected growth rates from PROGNOSIS are in fact being realized on the ground.

Question 2 added to tie silvicultural practices to integrated resource management.

Question 3 added to meet RPA section 3(d)(1) for identification of lands with stands of trees not growing at best potential rate.

FOREST PLAN MONITORING WORKSHEET

ISSUE: REFORESTATION

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Minimize the amount of time between the removal of existing trees and reforestation with desired species.

MANAGEMENT AREAS AFFECTED: All those where timber harvest occurs.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTIONS:

1. Is stocking for each management area and silvicultural method achieved within the time frame established?
2. Have adequate numbers of trees of desired species been established to realize optimum growth for the management area?

THRESHOLD OF VARIABILITY:

1. The average elapsed time from harvest to reforestation is 3 years or less on 90% of the acres harvested.
2. Average number of trees of desired species are within 10% of recommended levels.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1. Use the annual accomplishment report to track areas harvested, site preparation completed date, and date of reforestation.

Annually.

2. Conduct field surveys.

Years 1 and 3 after planting.

RESPONSIBILITY: District Ranger and Timber & Visual Resource Management Staff Officer

ANNUAL COST OF MONITORING: \$100,000 Most of this cost is for the field surveys which we are already doing.

REMARKS: This item is intended to test the planning premise supporting planned ASQ. We need to track accomplishment of site preparation within 1 year of availability of the unit and reforestation within 3 years unless there are documented extenuating circumstances.

Question 2 added to meet RPA section 3(d)(1) and NFMA 36 CFR 219.12(k)(5).

FOREST PLAN MONITORING WORKSHEET

ISSUE: LANDS NOT SUITABLE FOR TIMBER MANAGEMENT

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Verify that technology and/or other information has not been developed to justify reclassifying lands from a not suitable status to suited, or vice versa.

MANAGEMENT AREAS AFFECTED: All management areas which include lands from which timber may be harvested.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTIONS:

1. Have the lands that were identified in the Plan as not being suitable for timber management now become suitable for timber management?

2. Is the suitable/not suitable land classification accurate as identified in the Forest Plan data base?

THRESHOLD OF VARIABILITY:

1. More than a 10 percent change in acres classified as unsuitable.
2. More than a 10 percent error in suitable/unsuitable classification.

SUGGESTED SAMPLING METHODS

Record Forest Plan data base in GIS. Update these records based on site specific analyses documented through the NEPA process. Records include reasons for lands being not suited.

REPORT PERIOD (YEARS):

Annual recording of information with a report at 10-year intervals that presents a discussion of the significance of findings.

RESPONSIBILITY: Timber & Visual Resource Management Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$12,000 We are not yet doing this.

REMARKS: Question 2 added to monitor accuracy of information going into Forest Plan. Important item because of direct relationship to acres being used to calculate ASQ.

FOREST PLAN MONITORING WORKSHEET

ISSUE: MAINTENANCE OF LONG-TERM SOIL PRODUCTIVITY

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage the soil resource by implementing management practices that maintain or enhance its productive properties.

MANAGEMENT AREAS AFFECTED: All management areas.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 3 = RISK INDEX 9

Soil is considered to be an irreplaceable resource. Although there is some possibility that compaction, displacement, loss of organic matter, and other changes can be rectified, cost are usually prohibitive. The risk of downstream impacts due to erosion and sedimentation are also usually costly.

MONITORING QUESTION:

Is soil productivity being adequately protected?

THRESHOLD OF VARIABILITY:

Less than 20% of an activity area is in a compacted, puddled or displaced condition; severely burned; or actively moving.

SUGGESTED SAMPLING METHODS: (Also see REMARKS) REPORT PERIOD (YEARS):

- | | |
|--|---|
| 1. Soil disturbance monitoring will be done in accordance with the Forest soil monitoring guide. | 1&2. Annually with a detailed report at 5-year intervals that discusses the significance of findings. |
| 2. For surface erosion - Utilize Allutn or other acceptable methodology on approximately 12 sites Forest-wide per year | |
| 3. For mass erosion, evaluation of individual mass failures larger than 200 cubic yards if mid-slope, or 50 cubic yards if in a streamside zone. | Variable as events occur. |
| 4. Tree growth measurements will be taken on twenty of the major soil types mapped on the Forest. Paired sample sites (disturbed vs. undisturbed) will be located on each soil type. Both foliar and soil test analysis will be made for each site and at the same frequency as are tree measurements. | At 10-year intervals per site. |

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer: District Rangers.

ANNUAL COST OF MONITORING: \$19,500 (Also see REMARKS) We are not yet doing this.

REMARKS: This monitoring effort will evaluate the individual effects of soil compaction, soil displacement, surface erosion, mass erosion, organic matter loss, and nutrient loss on long-term soil productivity.

Monitoring may require the combined skills of a soil scientist, a research scientist, silviculturist, and one or more technicians. The specific project analysis will need to be scheduled on a district basis and carried out as a district project, but coordinated through the Supervisors office so that duplications of sites does not become a problem. PNW Forest & Range Research Station scientists will be asked to assist in the evaluation of the monitoring procedures and results.

1.Soil compaction/displacement/puddling monitoring - Monitor 20% of tractor harvested acres per year; Approximately 10,000 acres are harvested each year of which, approximately 30% is harvested by tractors. Therefore, 20% of the 3000 acres would be 600 acres per year. Distribute monitoring over the Forest on a weighted basis by District.

2.Surface erosion monitoring - Select timber harvest area, wildfire area, or other disturbed site that could directly effect water quality and or fish habitat.

3.Mass erosion monitoring - Monitoring this kind of condition may require the use of several different skills: geologist, soil scientist, silviculturist, and watershed technician. Monitoring should evaluate both management related mass failures and naturally occurring mass failures that have a potential adverse effect upon water quality or fish habitat. We should be trying to determine the cause/effect relationships of each event we monitor. An emphasis should be placed on determining the cause/effect relationships of mass erosion events.

Monitoring of individual events: Case by case basis. Field drilling and seismic analysis usually needs to be done at least two times per year (spring and fall). Cross sections and measurements need to be done when the soil mass has stopped moving for the season and it is dry enough support equipment and people. This is also a good time to establish and monitor the photo points. Photo points should be retaken at least every 5 years.

4.Tree growth monitoring - site selection will be based on soil types. Coordinate tree growth measurement work with the timber stand exam program wherever possible. The foliar and soil samples will be taken each time that tree measurements are taken. The local PNW Research Soil Scientist will be asked to help write the monitoring plans and also to interpret monitoring results.

ANNUAL COST OF MONITORING (Continued)

1.Estimated cost for monitoring soil compaction/displacement/puddling:
\$6,000.00/year (approximately 6 timber sales/year)

2.Estimated costs for surface erosion monitoring:
Estimate \$300.00/site X 12 sites/year = \$3,600.00

3. Estimated costs for mass erosion monitoring:

a. Photo analysis : 20 days/district x \$125/day
\$2,500.00/District x 1 District/year = \$2,500
(assumes resource photo availability)

b. Costs to monitor specific events will vary greatly depending on the size, location, etc.
Costs could run as high as \$10,000.00 per occurrence if drilling/seismic and survey work is required. Photo point monitoring of an event could average \$200/site.

4. Estimated cost for monitoring tree growth:

Field - \$250.00/site (ten paired sites per year) = \$5000.00
Lab analysis - foliar = \$50.00/sample X 20 samples = \$1000.00
soil = \$50.00/sample X 20 samples = \$1000.00
\$7000.00 Total/yr

FOREST PLAN MONITORING WORKSHEET

ISSUE: FISH HABITAT TRENDS FOR MANAGEMENT INDICATOR SPECIES

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain or enhance fish habitat capability to at least retain existing capability.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTION:

Are the habitat trends for Management Indicator Species stable to improving, based on fish production objectives (anadromous) and habitat capability (resident)?

THRESHOLD OF VARIABILITY:

A declining trend in habitat in a drainage for a specific species.

SUGGESTED SAMPLING METHODS;

Anadromous fish numbers obtained from Washington Dept. of Fisheries (spawning and dam counts). Resident population trends (including bull trout) coordinated with Washington Dept. of Wildlife index spawning surveys.

REPORT PERIOD (YEARS):

Annual surveys with a detailed report at 5 year intervals that discussed the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soil Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$6,000 of which we are doing \$1,000

REMARKS: Significant coordination required with fish management agencies.

Baseline stream inventory and project level stream inventory will augment this information on indicator species population trends.

These monitoring efforts are closely linked with those for several other issues, such as the evaluation of long-term trends in watershed condition and fish habitat capability. Refer to other Soil, Water and Fish Habitat Monitoring Worksheets for more detailed information regarding each monitoring component and its linkages within the program.

FOREST PLAN MONITORING WORKSHEET

ISSUE: EFFECTS OF FOREST MANAGEMENT ON RIPARIAN DEPENDENT RESOURCES, INCLUDING WATER QUALITY, FISH AND WILDLIFE HABITAT

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide riparian habitat as specified in the Forest-wide Standards and Guidelines to meet water quality, fish and wildlife habitat objectives.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: $\text{COST OF ERROR}_3 \times \text{LIKELIHOOD OF ERROR}_3 = \text{RISK INDEX}_9$

- Sensitivity of riparian areas/riparian dependent resources
- Water quality is a major public concern
- Emphasis on fish habitat management to meet "Rise to the Future" program, Indian Treaty rights, and NWPPC goals for anadromous fish production.

MONITORING QUESTION:

Is project implementation resulting in expected conditions for riparian areas?

THRESHOLD OF VARIABILITY:

Non-attainment of a practice or set of practices with Forest Plan standards and guidelines, such as those for riparian area management and water quality.

SUGGESTED SAMPLING METHODS:

EA review with field review of a sample of projects for implementation and effectiveness.

REPORT PERIOD (YEARS):

Annual review with a detailed report at 5-year intervals that presents a discussion of the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$26,000 (Also see REMARKS) We are doing about \$5,000 now

REMARKS: The following guidance for implementation and effectiveness monitoring of project activities is considered a minimum level program to address this issue. It must be recognized that this monitoring effort will be supplemented by other components of the Forest-wide program, such as implementation monitoring that will occur during project activity as regular support, soil productivity monitoring, etc.

If a specific project or area requires a more intensive monitoring effort, then that should be prescribed in the project NEPA document.

SUGGESTED SAMPLING METHODS

1. Implementation Monitoring - Evaluation of the extent and quality of implementation of management practices prescribed in the project NEPA document. Include an evaluation of whether the proper practices and controls were included in the NEPA document as well as an assessment of their implementation. (See footnote for suggested minimum sample size.)

a. Review NEPA documents/contracts to determine if Forest Plan standards and guidelines and management prescriptions are being included in project design.

b. On-site review of a sub-sample of completed projects to determine if practices are being implemented as planned in the NEPA document.

2. Effectiveness Monitoring - Evaluation of the extent to which management practices prescribed in NEPA documents meet Forest-wide standards and guidelines.

a. On-site review of a sub-sample of completed projects to evaluate overall compliance with Forest-wide standards and guidelines. See following for suggested sample size.

Suggested minimum sample size by resource element:

Timber: at least 1 completed timber sale/district/year (completed thru slash disposal activities); emphasis on monitoring of road construction and maintenance activities as well as the effectiveness of riparian zone treatments.

Range: at least one allotment/year on the Forest; Also refer to the "Range Forage Condition" monitoring worksheet for information on riparian area and upland monitoring of the range resource.

Recreation (ORV, Wilderness Uses)/Minerals/Special Uses: as identified in the project NEPA document.

b. Monitoring of a sub-sample of projects before, during and after activity to evaluate effectiveness of practices and projects in meeting Forest-wide standards and guidelines. Emphasis on quantitative assessment using such parameters as stream temperature, turbidity, sediment deposition, etc.

(1) Emphasis on timber harvest/roading activities.

(2) This component of effectiveness monitoring will be coordinated Forest-wide. Emphasis will be placed on collection of quality data on a limited number of projects. Suggested minimum sample size 3 large sales during the first half of the 10 year timber sale action plan.

(3) This level of effectiveness monitoring will involve integration of monitoring results from the following levels:

- **On-site monitoring** of practice/project on the slope
- **Upstream tributary monitoring** of channel conditions within or immediately adjacent to the activity area
- **Mainstream monitoring** of conditions at a downstream critical reach

(4) Refer to worksheet on Maintenance of Long-Term Soil Productivity for details regarding project monitoring for the soil resource.

c. Soil, Water and Fish Habitat Resources - See monitoring worksheet for "Trends in watershed condition and fish habitat capability".

d. Wildlife Habitat Capability in Riparian Areas - Population trend data for Ruffed Grouse and Beaver will be obtained from WDW. Plots will be established in a sub-sample of Class III and IV streams to evaluate population trends for amphibians after timber harvest activities (1-5 years).

ANNUAL COST OF MONITORING (Continued)

For water quality/fish habitat = \$22,500

For riparian wildlife habitat = \$3,500

FOREST PLAN MONITORING WORKSHEET

ISSUE: CUMULATIVE EFFECTS OF FOREST MANAGEMENT ACTIVITIES ON WATERSHED

CONDITION AND FISH HABITAT

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage the soil resource of the Forest by using management practices that will maintain or enhance its productive properties. Maintain watershed condition to ensure meeting or exceeding State water quality standards. Maintain and improve current and long-term fish habitat capability.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 3 = RISK INDEX 9

MONITORING QUESTION:

Are activities being scheduled in time and space in a manner that minimizes the potential for adverse cumulative effects on watershed condition and fish habitat?

THRESHOLD OF VARIABILITY:

The threshold for this issue is related to the results from other monitoring elements such as fish habitat capability and population trends, watershed condition, and meeting or exceeding State water quality standards.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

Review the results of other monitoring items and evaluate project EAs with field observations including evaluation of activities on land in other ownerships. (See REMARKS section for more detail.)

Annual review with a detailed report at 5-year intervals that discusses the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$6,000 of which we are doing \$1,000

(Cost for data compilation and evaluation; assumes data from individual monitoring efforts have already been compiled and interpreted)

REMARKS: This monitoring effort is closely linked with those for most other issues, especially to the evaluation of baseline trends in watershed condition and fish habitat. Refer to the "TRENDS IN WATERSHED CONDITION AND FISH HABITAT CAPABILITY" for more detailed information regarding this monitoring component and its linkages within the program.

SUGGESTED SAMPLING METHODS

Provide for an integrated analysis of project planning, scheduling and monitoring results for watersheds. This analysis will include:

1. Compilation and evaluation of ten year timber sale action plans, project EAs, harvest records, IDT evaluations of project compliance with EAs and contracts and information on activities on lands in other ownerships.

2. Compilation and evaluation of monitoring results, such as baseline trends in water quality and fish habitat, effects of forest management activities on watershed condition and fish habitat, etc. as outlined under other monitoring issues.

Review of project scheduling and analyses should occur annually on a sample basis. Review of monitoring results for identification of cumulative effects should occur on a subdrainage basis at least every five years.

FOREST PLAN MONITORING WORKSHEET

ISSUE: TRENDS IN WATERSHED CONDITION

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage the soil resource by using management practices that will maintain or enhance its productive properties. Maintain watershed condition to ensure meeting or exceeding water quality goals as defined by standards established by the State of Washington. Maintain and improve current and long-term fish habitat capability.

MANAGEMENT AREAS AFFECTED: Forest-wide

RISK ASSESSMENT: $\text{COST OF ERROR}_3 \times \text{LIKELIHOOD OF ERROR}_3 = \text{RISK INDEX}_9$

Until additional information is available on current conditions and effectiveness of standards and guidelines, a relatively high risk exists that we may not meet management objectives.

MONITORING QUESTION:

What are the long-term trends in watershed condition as expressed by changes in soil productivity, water quality, and fish habitat capability?

THRESHOLD OF VARIABILITY:

For soil productivity - see worksheet for "Maintenance of Long-Term Soil Productivity."

For fish habitat capability - any measurable decrease. (The trend in fish habitat capability is considered to be a sensitive index of watershed condition.)

For water quality - failure to meet Federal and State water quality standards.

SUGGESTED SAMPLING METHODS: REPORT PERIOD (YEARS):

See the REMARKS section for details.

Because of the time needed to gather baseline information and have enough data for comparisons evaluations can be made, the first detailed report will be in 10 years. Reports for subsequent periods will be at 5-year intervals.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: Year 1-5 = \$28,500 we are not doing any of this yet.
Year 6-10 = \$53,500 (Also see REMARKS)

REMARKS:

SUGGESTED SAMPLING METHODS

The first thing we need to address this subject is a completed stream survey. From there we can determine the most appropriate locations for monitoring stations on streams and lakes. The process to gather information is explained in this section.

This inventory/monitoring effort will be coordinated with state and other Federal fish and environmental agencies, Indian tribes and private groups.

Baseline Stream Inventory

A major benefit of the stream inventory program will be the ability to compare the data collected for monitoring purposes. An accelerated stream inventory program is scheduled during the first 3-5 years of Plan implementation (approximately 300 stream miles/year). This program will be a coordinated effort between watershed and fish habitat resources, funded as a basic inventory.

Following this initial effort, approximately 100 stream miles will be inventoried each year for the purposes of baseline monitoring. The total annual cost of this monitoring effort is estimated to be approximately \$25,000.00/year (distributed 2/3 fish, 1/3 watershed; beginning year 5).

Baseline stream inventory will include the following parameters:

- habitat units (e.g., pool, riffle, etc.)
- riparian standards (e.g., large wood per unit distance)
- channel type (Rosgen or other)
- cover
- substrate
- hydraulic parameters (e.g., bankfull width, etc.)
- fish populations (e.g., snorkel counts)
- evaluation of migration obstacles

Project level inventory data will be available to supplement the baseline inventory. This project level inventory will involve more detailed information on specific stream reaches.

Baseline Monitoring Network - Streams

Baseline monitoring provides broad overview coverage of the Forest. Baseline monitoring sites on selected streams and lakes representatively sample conditions on the Forest, serving as indicators of long-term trend and to characterize the resource. These sites may also serve as monitoring sites for project level monitoring.

Parameter selection will emphasize those factors for which standards have been defined, such as Forest-wide standards for riparian area condition. For example, selected parameters for streams would include characteristics such as stream temperature, sediment deposition in fish habitat, and macroinvertebrates.

1.Streams

The baseline monitoring network would consist of approximately 25 stations distributed across the Forest. Data from this network would be supplemented by information from climatic stations and stream gages operated by the National Weather Service, Soil Conservation Service and the U.S. Geological Survey. Information from the latter sources will be used for resource characterization and background data for predictive purposes in the analysis of likely consequences of projects.

An annual cost estimate for support of a baseline stream monitoring network would be as follows:

a. Estimate 25 stations Forest-wide, parameters as follows:

- (1) Temperature monitoring: 10 of 25 stations
- (2) Core sampling: 10 stations
- (3) Cobble embeddedness: 25 stations
- (4) Macroinvertebrate monitoring: 10 stations
- (5) Other physical/chemical/biological water quality parameters: 5 stations
- (6) Other stream channel parameters, such as bed material composition: all stations

b. Estimated network cost (25 stations)

(1) Temperature monitoring	\$ 1,330
(2) Core sampling	\$ 5,000
(3) Cobble embeddedness	\$ 5,000
(4) Macroinvertebrates	\$ 6,000
(5) Phy/Chem/Bio	\$ 1,500
(6) Stream channel parameters	<u>\$ 5,000</u>
	\$24,000

2. Lakes

Evaluation of habitat capability and population trends on a minimum of 10 lakes in coordination with WDW. Coordination emphasis on monitoring of growth and catch rates. Integrate this effort with baseline monitoring for the air resource management program. Estimated cost for evaluation of 5 lakes per year is \$4,500.

Costs summarized from the above narrative:

Baseline Monitoring -Streams \$24,000/year during years 1-10
Network -Lakes \$4,500/year during years 1-10

Baseline Stream Inventory \$25,000/year during years 6-10

TOTAL Years 1-5 \$28,500
Years 6-10 \$53,500

These monitoring efforts are closely linked with those for several other issues, such as the evaluation of the cumulative effects of forest management activities on fish habitat capability.

FOREST PLAN MONITORING WORKSHEET

ISSUE: **RANGE OUTPUTS**

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Manage the range resource to maintain and improve vegetative conditions. Full utilization of forage allocated to livestock will be encouraged.

MANAGEMENT AREAS AFFECTED: All areas where livestock grazing is permitted.

RISK ASSESSMENT: $\text{COST OF ERROR}_2 \times \text{LIKELIHOOD OF ERROR}_2 = \text{RISK INDEX}_4$

MONITORING QUESTION:

Are the annual outputs (AUMs) for permitted commercial livestock being achieved as projected in the Forest Plan?

THRESHOLD OF VARIABILITY:

A 10% change from projected AUM outputs.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

Review and compare actual with predicted AUM outputs from the annual grazing statistical reports.

Annually with a detailed report at 5-year intervals that describes the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$3,000 of which we are doing \$2,000

REMARKS:

FOREST PLAN MONITORING WORKSHEET

ISSUE: FORAGE UTILIZATION

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide opportunities to enhance other resource values through the use of livestock to shape desired plant communities.

MANAGEMENT AREAS AFFECTED: All areas where livestock grazing is permitted.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTION:

Are the forage utilization levels consistent with goals for riparian and upland areas?

THRESHOLD OF VARIABILITY:

A 10% increase in forage utilization over prescribed standards with a resulting downward trend in condition in riparian and upland areas.

SUGGESTED SAMPLING METHODS: REPORT PERIOD (YEARS):

Using FSH 2509.21, sample at least 30% of allotments annually with all sampled at least once every 4 years. Highest priority is in known or suspected problem areas.

Annually with a detailed report at 5-year intervals that provides a discussion of the significance of findings.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$5,000 We are doing all of this now.

REMARKS: Riparian area sampling is a shared monitoring item with watershed, fish and wildlife.

FOREST PLAN MONITORING WORKSHEET

ISSUE: RANGE FORAGE CONDITIONS

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Improve forage condition with an upward trend in ground cover and species composition, contributing to the protection and enhancement of soils, watershed and wildlife forage.

MANAGEMENT AREAS AFFECTED: All areas where livestock grazing is permitted.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTIONS:

1. Is vegetation condition and trend being maintained or improved in riparian and upland areas, so as to meet Forest Plan objectives?
2. Have areas in unsatisfactory condition improved to satisfactory condition?

THRESHOLD OF VARIABILITY:

1. An 10% or greater increase in area showing a downward trend.
2. An upward trend for an area previously identified as being in an unsatisfactory condition.

SUGGESTED SAMPLING METHODS

REPORT PERIOD (YEARS):

Riparian areas: Terrestrial transects and photographs, stream channel cross-section measurements, stream-bank condition evaluation (Haugen, 1987), photo point standard documentation ("Recording the changes", R-6-10-095-1982). Observations, temperature measurements. Comparison with "PC" criteria.

Annually with a detailed report at 5-year intervals that presents a discussion of the significance of findings.

Upland areas: Condition and trend transects, field observations, photo points ("Recording the Changes" R-6-10-095- 1982).

As established in allotment management plans but at least once every 10 years.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$20,000 of which we are doing \$10,000

REMARKS: Riparian area sampling will be shared with watershed, fish and wildlife. This monitoring is that which is in addition to the normal amount of sampling in riparian areas which would occur without the special riparian area distinction.

FOREST PLAN MONITORING WORKSHEET

ISSUE: RANGE IMPROVEMENTS

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain all structural improvements at, or as near as possible to, the standard to which they were constructed.

MANAGEMENT AREAS AFFECTED: All areas where livestock grazing is permitted.

RISK ASSESSMENT: $\text{COST OF ERROR}_2 \times \text{LIKELIHOOD OF ERROR}_1 = \text{RISK INDEX}_2$

MONITORING QUESTIONS:

Are structural range improvements being maintained so that they continue to function at the level they were intended?

THRESHOLD OF VARIABILITY: Ten percent of improvements are not functioning as designed.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

Review allotment records and a sample structural improvements.

Annually with detailed reports at 5-year intervals.

RESPONSIBILITY: Range, Wildlife, Fish, Water and Soils Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$6,000 of which we are doing \$3,000

REMARKS:

FOREST PLAN MONITORING WORKSHEET

ISSUE: ROAD MILEAGE AND MANAGEMENT

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: To plan, design, operate, and maintain a safe economical transportation system providing efficient access for the movement of people and materials involved in the use and protection of National Forest lands.

MANAGEMENT AREAS AFFECTED: All areas where roads are appropriate.

RISK ASSESSMENT: $COST\ OF\ ERROR\ 2 \times LIKELIHOOD\ OF\ ERROR\ 1 = RISK\ INDEX\ 2$

MONITORING QUESTIONS:

1. Does the transportation system serve the intended resource objectives for the management area?
2. How do the miles of road construction estimated in Forest Plan schedules compare with actual construction?

THRESHOLD OF VARIABILITY:

1. No variability, all non conforming projects will be redesigned.
2. The miles should be within 25% of annual projections and within 10% for the 10 year period.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD:

1. Conduct an interdisciplinary field review of a sample of road projects and the transportation system serving specific management areas.

Annual review with a report at 5 year intervals that includes a discussion of significant findings.

2. Record accomplishment in various existing systems such as STARS, TSPIRS, Roads, etc.

Annual recording with a detailed report at 5 year intervals.

RESPONSIBILITY: District Rangers and Engineering, Lands and Minerals Staff Officer

ANNUAL COST OF MONITORING: \$8,000 of which we are doing \$6,000

REMARKS: Question 2 added to address issue of road management and cost.

FOREST PLAN MONITORING WORKSHEET

ISSUE: INSECT AND DISEASE CONTROL

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Assure that management practices do not contribute to increases in the incidence of destructive insects and diseases such as spruce budworm, Douglas-fir tussock moth, pine beetle, mistletoe, root rots, and others.

MANAGEMENT AREAS AFFECTED: All forested lands.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTION:

Are destructive insect and disease organisms remaining below potentially damaging levels following management activities?

THRESHOLD OF VARIABILITY:

Insect populations and/or infection centers show an increase since the last measurement/survey.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

1. Review of ID&C survey maps to determine trends.
2. Conduct special surveys to determine effects on growth.

1. Annually review with report at 5 year intervals that present a discussion of the significance of findings.
2. A field survey at 10 year intervals.

RESPONSIBILITY: Timber & Visual Resource Management Staff Officer; District Rangers.

ANNUAL COST OF MONITORING: \$5,000 of which we are doing \$1,000

REMARKS: This item is intended to track the effects of insect and disease agents on Forest stands and their effect on growth rates.

FOREST PLAN MONITORING WORKSHEET

ISSUE: **FOREST FIRE PROTECTION**

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide protection from wildfire for forest users, improvements, and forest resources in an efficient manner.

MANAGEMENT AREAS AFFECTED: Forest-wide.

RISK ASSESSMENT: COST OF ERROR 3 X LIKELIHOOD OF ERROR 2 = RISK INDEX 6

MONITORING QUESTIONS:

1. Are implemented fire suppression strategies adequately protecting the public, improvements, and forest resources?
2. Are the costs of protection in line with those projected by the National Fire Management Analysis System?

THRESHOLD OF VARIABILITY:

1. A decrease greater than 15% in the ability of the Forest to provide any of the resource outputs outlined in the Plan.
2. If the total fire program costs (FFP + FFF) and resource loss exceed the value described in the most current NFMAS documentation by more than 20% for two consecutive years.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS):

- | | |
|---|---|
| 1. Compare expected outputs with accomplishment. | 1&2 Annually with a report at 5 year intervals that discusses the significance of findings. |
| 2. Review program costs and resource loss for each fiscal year. | |
| Review fire suppression costs and resource losses for each fire that exceeds 100 acres. | As needed. |

RESPONSIBILITY: Air, Fire & Aviation Staff Officer, and District Rangers.

ANNUAL COST OF MONITORING: \$7,000 of which we are doing \$3,500

REMARKS: Interagency coordination is a major portion of the workload. The monitoring costs include time to accomplish the following: 1) Update NFMAS; 2) Ensure compliance with National, Regional, and Forest policy and standards; 3) Work with other disciplines and agencies to review the appropriateness of fire suppression actions.

FOREST PLAN MONITORING WORKSHEET

ISSUE: USE OF PRESCRIBED FIRE

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Appropriate, efficient application of prescribed fire in support of the Forest Management program.

MANAGEMENT AREAS AFFECTED: All areas where this tool is appropriate.

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 2 = RISK INDEX 4

MONITORING QUESTIONS:

1. Are the acres being treated with prescribed fire meeting expected resource management objectives?
2. Are forest fuel loadings exceeding natural levels and therefore placing Forest users, improvements, and/or resource values at risk?

THRESHOLD OF VARIABILITY:

1. Acres treated are for the purposes prescribed and within 25% of annual projections and 10% for the decade.
2. Fuel loadings, expressed in tons/acre, are within 25% of those expected under natural conditions. Risk assessment is a subjective evaluation with no identifiable threshold.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD (YEARS)

- | | |
|---|---|
| 1. Review smoke management documentation, burn plan objectives, and results of completed activity. | Annually with a detailed report at 5 year intervals that presents a discussion of the significance of findings. |
| 2. Fuel loading inventories in conjunction with an assessment of the significance of the findings relative to nearby areas. | Part of Forest inventoried annually with a report at 5 year intervals. |

RESPONSIBILITY: District Rangers; Air, Fire & Aviation Staff Officer.

ANNUAL COST OF MONITORING: \$30,000 of which we are doing \$10,000

REMARKS: This item applies to all uses of prescribed fire, not just the need to use fire as a tool for site prep and fuel reduction.

FOREST PLAN MONITORING WORKSHEET

ISSUE: AIR RESOURCE MANAGEMENT

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Maintain air quality in conjunction with all cooperating agencies.

MANAGEMENT AREAS AFFECTED: Forest-wide.

RISK ASSESSMENT: COST OF ERROR 1 X LIKELIHOOD OF ERROR 2 = RISK INDEX 2

Errors result in short-term degradations which could have long-term effects on how forest management activities are viewed by the public. Likelihood of error is moderate because of the variability of weather and our ability to accurately predict.

MONITORING QUESTIONS:

1. Are the impacts on air quality being considered in the management activities being proposed?
2. Is the Forest in compliance with direction outlined in the Clean Air Act, the Washington State Implementation Plan, and National Forest Policy?

THRESHOLD OF VARIABILITY:

1. All NEPA documents for projects with a potential to affect air quality include an evaluation of the likely effects of proposed activities on air quality.
2. Violation of the Washington State Smoke Management plan will initiate review. Negative effects on Air Quality Related Values in any Class I area will result in review.

SUGGESTED SAMPLING METHODS: REPORT PERIOD (YEARS)

- | | |
|---|---|
| 1. Review a sample of NEPA documents. | 1&2 Annually with a detailed report at 5-year intervals that presents a discussion of the significance of findings. |
| 2. Examine smoke management documents. Review consumption documentation on 20% of prescribed fire projects. | |

RESPONSIBILITY: District Ranger; Air, Fire & Aviation Staff Officer.

ANNUAL COST OF MONITORING: \$10,000 of which we are doing \$3,000

REMARKS: This is a rapidly expanding program. Priority projects include implementing an Air Quality Related Values Monitoring Plan for the Alpine Lakes Wilderness and establishing baseline values for this airshed. Second priority is to establish AQRVs for additional wildernesses on the Forest and expand monitoring program as necessary. Additional skills may be needed to deal with modeling programs which involve atmospheric variables.

An additional \$50,000 to \$100,000 will be spent annually on monitoring Air Quality Related Values associated with the Class I Wilderness Airsheds. That kind of monitoring is beyond the scope of the effort needed for monitoring the effects of implementing the Forest Plan and is not a part of this plan.

FOREST PLAN MONITORING WORKSHEET

ISSUE: COMMUNITY EFFECTS

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide local communities with a constant source of opportunity for the use of goods and services that provide for desired community growth. Changes in the kinds of business opportunities available today are likely over time.

MANAGEMENT AREAS AFFECTED: Forest-wide.

RISK ASSESSMENT: $\text{COST OF ERROR}_3 \times \text{LIKELIHOOD OF ERROR}_1 = \text{RISK INDEX}_3$

MONITORING QUESTIONS:

1. Are payments to Counties changing?
2. Are local populations changing?
3. Are local employment patterns changing?
4. Are payments to counties changing?
5. Are lifestyles, attitudes, beliefs or values changing?
6. Are Forest contributions to area forest products industries changing?

THRESHOLD OF VARIABILITY:

1. $\pm 25\%$ annual change.
2. Subjective analysis.
3. Subjective analysis.
4. $\pm 25\%$ annual change.
5. Subjective analysis.
6. Subjective analysis.

SUGGESTED SAMPLING METHODS:

REPORT PERIOD: Annual

1. U.S. Census, State Publications, County and local agency reports.
2. U.S. Census, State Publications, County and local agency reports.
3. U.S. Census, State Publications, County and local agency reports.
4. Review Payments to Counties Reports.
5. Interviews.
6. Tracking of raw material flow to mills, industry mix.

RESPONSIBILITY: Planning Staff Officer.

ANNUAL COST OF MONITORING: \$5,000 of which we are doing \$2,500

REMARKS: The National Forest is recognized as a major attraction by many adjacent communities. Revenues generated from National Forest programs are also an important aspect of local community economic health.

FOREST PLAN MONITORING WORKSHEET

ISSUE: **RESOURCE BUDGETS**

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Provide funding levels necessary to achieve outputs in Forest Plan.

MANAGEMENT AREAS AFFECTED: All

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 1 = RISK INDEX 2

MONITORING QUESTION:

Are the budgets received adequate for achieving the objectives described/ projected in the Forest Plan?

THRESHOLD OF VARIABILITY:

Outputs are within 20 percent of figure specified by Forest Plan. If outputs are below this level, monitor resource budgets to see if they are the reason for the fall down in output.

SUGGESTED SAMPLING METHODS:

Comparison of budgets and outputs in the Forest Plan with budgets received and outputs actually produced.

REPORT PERIOD (YEARS):

Compare annually with a more detailed report at years 3, 5, and 7 to verify that trends are consistent with projections for output and service levels.

RESPONSIBILITY: Planning Staff Officer

ANNUAL COST OF MONITORING: \$3,500 We are not doing any of this yet.

REMARKS: Addresses requirement in 36 CFR 219.12(k): Quantitative estimate of performance comparing outputs and services with those projected by the Forest Plan.

Intent of this item is to keep track of budget trends so timely adjustments can be made. May need to look at a wider range of funding sources to adequately monitor; i.e., challenge cost share, partnerships, etc. in addition to CIP and other appropriated dollars.

It is more important to achieve outputs and services than to concentrate on the question of whether we got the funding we estimated we needed.

FOREST PLAN MONITORING WORKSHEET

ISSUE: COSTS AND VALUES

FOREST GOALS, DESIRED FUTURE CONDITION, OUTPUTS: Implement the Forest Plan in a cost efficient manner.

MANAGEMENT AREAS AFFECTED: N/A

RISK ASSESSMENT: COST OF ERROR 2 X LIKELIHOOD OF ERROR 3 = RISK INDEX 6

MONITORING QUESTIONS:

1. Are major costs used in Forest Plan analysis consistent with actual implementation costs?
2. Are current values for Forest resources consistent with those used in Forest Plan analysis?

THRESHOLD OF VARIABILITY:

1. Moving average of costs for past three years is within 25 percent of those in the Forest Plan.
2. Moving average of timber values for past five years is within 25 percent of those used in Forest Plan. Other values will come from RPA updates and should be within 25 percent of Forest Plan costs.

SUGGESTED SAMPLING METHODS:

1. Costs can be determined by reviewing unit costs in PAMARS.
2. Timber values determined from cut & sold reports; developed recreation values in part from fee site records; other values from RPA.

REPORT PERIOD (YEARS):

1&2. Annual review with a detailed report at 5-year intervals that discusses the significance of findings.

RESPONSIBILITY: Forest Economist

ANNUAL COST OF MONITORING: \$3,500 We are not doing any of this yet.

REMARKS: Major costs include capital investment costs for recreation, trails, fish and wildlife, range and timber. Timber costs that need monitoring are reforestation, timber stand improvement, timber sale support, timber sale preparation and administration.

Question 1 responds to 36 CFR 219.12(k) requirement: Costs associated with carrying out planned management prescriptions as compared with costs estimated in the Forest Plan.

Purpose of monitoring is to validate those costs and values used in Forest Plan analysis. Significant differences could result in revisions because of changes in suitability/efficiency of producing some resource outputs or in application of specific S&G.

RECORD OF DECISION

I. INTRODUCTION

BASIS AND NEED FOR DECISION

This Record of Decision documents my decision and rationale for approving the Land and Resource Management Plan (also referred to as the Plan or the Forest Plan) for the Wenatchee National Forest.

A record of decision is required by the Council on Environmental Quality regulations for implementing the National Environmental Policy Act (40 CFR 1500 et seq.) when a Federal agency undertakes an action requiring an environmental impact statement.

The Final Environmental Impact Statement (FEIS) and Forest Plan were developed under the implementing regulations of the National Environmental Policy Act (NEPA), Council on Environmental Quality (40 CFR 1500-1508) and the National Forest Management Act (NFMA, 36 CFR 219).

The Plan is part of the 50-year framework for long-range resource planning established by the Forest and Rangeland Renewable Resources Planning Act (RPA) as amended by the National Forest Management Act (NFMA). As such, it establishes general direction for a period of time, usually between 10 and 15 years. Information regarding outputs and effects beyond this period are provided only to broadly indicate the currently anticipated consequences of each Plan alternative if it is selected to continue into the future. However, the Plan must be revised at least every 15 years. Once adopted, the Plan replaces all previous resource management plans prepared for the Forest, subject to existing rights, contracts, and specific direction for special areas such as Wilderness, Wild and Scenic Rivers, National Recreation Areas, and National Trails. One exception is the Alpine Lakes Land Management Plan which was Congressionally mandated. The management direction from this plan has been incorporated into the Forest Plan.

In publishing the Forest Plan, the Forest Service is trying to satisfy two purposes

Compliance with the statutory mandate of NFMA to develop and maintain a management system so that an "interdisciplinary approach to achieve integrated consideration of physical, biological, economic, and other agencies" will be applied to all future decisions (16 USC 1604(b), (c), (f), and (g)).

Linkage with the Forest and Rangeland Renewable Resource Planning Act (RPA) Program and Assessment through current modeling techniques to make forecasts of outputs which could be produced under the Forest Plan and alternatives to the Forest Plan.

Production levels for various uses presented in the Plan are projections. While all outputs in the Plan can be accomplished from a physical, biological, economic, and legal perspective, the Forest Plan does not guarantee these levels will be accomplished. However, these projections will be adjusted as needed through amendments or revision of the Plan.

The Forest Plan provides a long-range management program for all natural and renewable resource management activities and determines general management requirements for implementation. It provides for coordinated multiple-use management of outdoor recreation, range, timber, watershed, wildlife and fish, minerals, and wilderness resulting in sustained yields of goods and services for the benefit of the American people.

AFFECTED AREA

The Wenatchee National Forest lies on the east side of the Cascade Mountain Range in Central Washington. It extends about 140 miles from north to south and an average of 35 miles east to west. The Forest has a net area of 2,164,180 acres, larger than Delaware and Rhode Island combined.

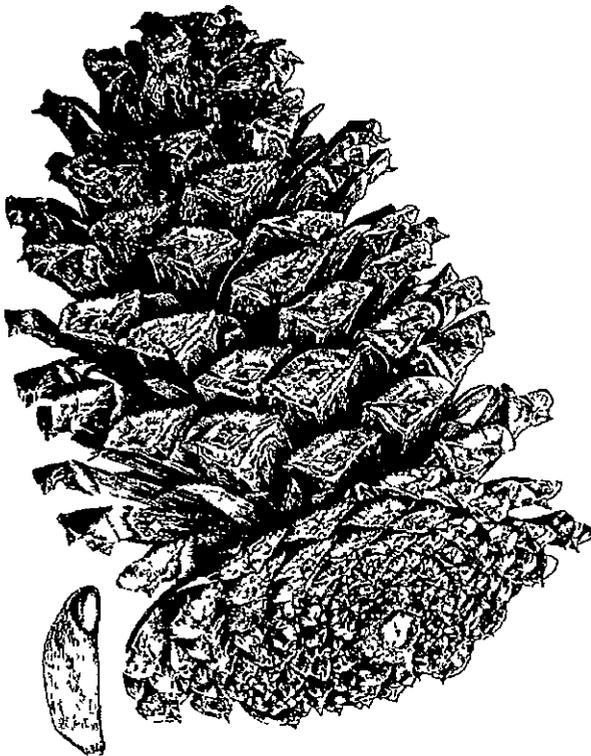

Steep, rugged mountains and heavy snowpacks characterize the western portions of the Forest. In contrast, near desert conditions prevail in the eastern grass and shrub covered foothills and valleys. Between the two extremes are diverse forest and plant communities resulting from the variations in soils, elevation, aspect, temperature, precipitation, and fire influences. Major drainage systems include the Chelan, Entiat, Wenatchee, and Yakima. Principal forest resources include timber, wildlife, fish, recreation, water, and wilderness. Almost two out of every five acres on the Forest (39 percent) are congressionally designated wilderness.

The Forest is primarily located in Chelan, Kittitas, and Yakima Counties, with two acres in Douglas County. The area administered by the Wenatchee National Forest and considered in this planning document includes a 515,843 acre parcel of the Snoqualmie National Forest. These lands are located on the Naches Ranger District in the southern portion of the Forest. In addition, an isolated 9,032 acre parcel of the Wenatchee National Forest in the Liberty Bell portion of Chelan County is being administered by the Okanogan National Forest and will be included in the Okanogan Forest Plan.

Major cities and towns in or near the planning area are Chelan, Entiat, Cashmere, Leavenworth, Wenatchee, and East Wenatchee in the north, Cle Elum, Roslyn, and Ellensburg in the center, and Yakima, Selah, and Naches in the south. More than 270,000 people live in the four county area. The Forest is also easily accessible from metropolitan Puget Sound with a population of well over two million people.

1989	Public Comment Period for Supplement to DEIS Evaluation of Public Comment Formulation, Analysis and Modification of Final Alternative Final Plan Published
1990	Plan Implementation, Monitoring and Evaluation

II. DECISION

WHAT THE DECISION IS AND IS NOT

The Forest Plan is a general strategy for managing the National Forest lands on the Wenatchee National Forest. It is not a plan for the specific administrative activities needed to carry on the Forest Service's day-to-day internal operations. For example, the Plan does not address personnel matters, fleet equipment, or internal organization changes. However, it is a plan for managing the Wenatchee National Forest System in an environmentally sound manner to produce goods and services in a way that maximizes long-term public benefits.

The emphasis of the Plan is not an aggregate of site-specific decisions or specific resource outputs. Rather, the emphasis is on applying various general management practices at various intensities to areas of land to achieve multiple-use goals and objectives in a cost efficient manner.

To respond to changing needs and opportunities, Congressional land designations, catastrophic events, new information and inventories, or major new management or production technologies, the Plan may have to be amended or revised. If there is a significant change to the Plan, it must be altered by a procedure identical to that used in the development and approval of the original Plan. If the change does not significantly affect the Plan, the Forest Supervisor may amend it by a less extensive procedure to include public notification.

ELEMENTS OF THE DECISION

The program decisions I make here are accompanied by the necessary supporting NEPA analysis and disclosure required by law and regulation. Additional NEPA analysis for these decisions is not expected to be done and is not required. A final decision may be revisited or reassessed during implementation, but it does not have to be. These decisions are as follows:

1. Forest-wide goals and objectives.
2. Forest-wide desired future condition.
3. Forest-wide standards and guidelines.
4. Management area goals and location.
5. Management area desired future condition.
6. Management area standards and guidelines.
7. Monitoring plan and evaluation process.
8. Incorporation of specific extant plans or projects. (For example, the Alpine Lakes Plan)
9. Identification (location) of lands considered suitable and selected for timber harvesting.
10. Establishment of the Forest-wide allowable sale quantity.

INTENDED ACTIVITIES

I also intend to accomplish certain scheduled activities. Unlike the programmatic decisions listed above, these are not accompanied by all supporting NEPA analysis and disclosure required by law and regulation. Additional NEPA analysis will be done during the implementation of the Plan. Those proposed and probable activities are discussed in the activity schedules in the appendix of the plan.

1. Forest-wide objectives (outputs).
2. Proposed and probable activities for each management area and roadless area as reflected in the activity schedule.

It is important to note that all proposals in the Plan can be accomplished from a physical, biological, economic, social, and legal perspective. It is not certain that these proposals will be accomplished. First, the outputs proposed by the Plan are projections or targets. Outputs are estimates and projections based on available inventory data and assumptions, subject to the annual budget. For example, the number of acre-feet of water meeting water quality goals is a target number the Forest will strive to attain. Another example is allowable sale quantity of timber. That is the maximum regulated volume of timber that can be sold over the planning period, not necessarily the volume that will be sold.

Secondly, all activities, many of which are interdependent, may be affected by annual budgets. The Plan is implemented through various site-specific projects, such as the building of a road, development of a campground, or the sale of timber. If the budget changes for any given year covered by the Plan, the projects scheduled for that year may have to be rescheduled. However, the goals and land activity assignments described in the Plan would not change unless the Plan itself were changed. If budgets change significantly over a period of several years, the Plan itself may have to be amended and, consequently, would reflect different target outputs and environmental conditions. The significance of budget related or other changes is determined in the context of the particular circumstances.

As a long-range strategy for the Forest, this Plan and accompanying Environmental Impact Statement are programmatic. During implementation, when the various projects are designed, more site-specific analyses are performed. These analyses may result in environmental assessments, environmental impact statements, or categorical exclusions and, possibly, an amendment or revision of the Plan. Any resulting documents are to be tiered to the Final Environmental Impact Statement for this Plan, pursuant to 40 CFR 1508.28.

RECOMMENDATIONS

I also am recommending certain decisions to others with the authority to make those final decisions. Like my final decisions, recommendations are accompanied by all supporting NEPA analysis and

disclosure required by law and regulation. However, the authority to make a final decision on the issue lies outside the authority of the Regional Forester. If the higher authority accepts the recommendation, the resulting final decision will not ordinarily be revisited or reassessed by the Forest Service during implementation.

Recommendations include:

1. Identification (location) of recommended additions to the Wild and Scenic Rivers System.
2. Identification (location) of recommended additions to the Research Natural Areas.

SUMMARY OF THE DECISION

My decision is to approve and adopt the Forest Plan which accompanies the Final Environmental Impact Statement, this decision is referred to as Alternative C for the management of the Wenatchee National Forest. Alternative C has been modified from the DEIS version in response to public comments and new information.

Changes include a revised spotted owl network, increased roadless area allocations, several new prescriptions, increased allowable timber sale quantity, increased acreage of special interest areas and an increase in the number of rivers recommended for inclusion into the Wild and Scenic River system.

FOREST MULTIPLE USE GOALS AND DESIRED FUTURE CONDITIONS

The Forest Plan establishes multiple use goals, objectives and desired future condition in Chapter IV. A summary of the goals follows:

Recreation

Provide a well balanced array of recreation opportunities across the breadth of the recreation opportunity spectrum in accordance with resource capability, public demands, and expectations for outdoor recreation.

Provide a diverse system of safe, well-maintained trails for the enjoyment of all users.

Respond to new opportunities to develop partnerships and joint ventures with other agencies and the private sector to magnify our abilities to meet expanding public demand for outdoor recreation.

Provide an information program to assist the public in understanding management of various resources and to assist them in their search for a variety of challenging and pleasing experiences

Provide for the identification, protection, interpretation, and management of cultural resources so as to preserve their historical, cultural, archaeological, and/or architectural values for the benefit of the public.

Maintain and enhance the visual landscape character of the Forest.

Provide to the Forest visitors a variety of landscape character with visually appealing scenery.

Wilderness

Manage designated wilderness to perpetuate wilderness character, natural ecologic processes and to provide appropriate outdoor recreation opportunities

Wildlife, Fish, and Sensitive Plants

Manage critical wildlife habitat to improve the status of threatened and endangered species to a point where they no longer need protection under the Endangered Species Act of 1973

Enhance habitat to prevent the need for listing species on the Regional Forester's sensitive species list.

Manage fish and wildlife habitats to provide for recreation opportunities for fishing, hunting, and viewing.

Protect, restore, and enhance current and long-term fish habitat capability.

Riparian Areas

Maintain and enhance riparian management areas to perpetuate their distinctive resource values to: (a) achieve and maintain habitat conditions necessary to maximize long-term natural production opportunities for desired fish species, (b) maintain water quality that meets or exceeds State AA Water Quality Standards, and (c) provide diverse wildlife habitat.

Range

Develop, protect and manage the range resource to maintain and improve vegetative conditions compatible with the management area goal.

Provide opportunities to enhance other resource values through the use of livestock to shape desired plant communities.

Timber

Provide for timber harvest to help meet local and national demand for wood products and provide an economic benefit to the American people.

Use silvicultural techniques that insure prompt and adequate regeneration of appropriate species. Optimize growth, minimize disease and insect losses, and protect or enhance long-term site productivity.

Manage vegetation to maximize total net public benefits compatible with management area objectives.

Provide information about the opportunities available through the timber management program including firewood, Christmas trees, greenery, post and poles, transplants, and other specialty products.

Provide silvicultural advice and information through the Cooperative Forestry Program to local private forest landowners.

Water

Maintain favorable conditions of streamflow to insure meeting or exceeding Federal and Washington State water quality standards.

Soil

Manage the soil resource of the Forest by using management practices that will maintain or enhance its productive properties.

Air

Prevent significant adverse effects of air pollutants and atmospheric deposition on Forest resources through compliance with the Clean Air Act and State and local regulations.

Minerals

Help meet the demand for mineral resources by encouraging and facilitating the exploration, development, and production of mineral and energy resources, while ensuring that these activities are integrated with the use and protection of other resources.

Lands

Strive towards a land ownership pattern that will provide for better management, protection, and access to the forest.

Provide for occupancy and use of National Forest System land consistent with this Forest Plan and applicable laws and regulations.

Provide energy and transportation corridors to meet Regional and National needs.

Facilities

Develop a transportation system that is designed and operated to standards appropriate to the planned uses, considering safety, cost of transportation, and effects upon lands and resources.

Provide for the development, betterment, and maintenance of fire and general purpose administrative facilities in support of National Forest System needs.

Maintain Forest facilities for the safety, enjoyment, and well-being of the user.

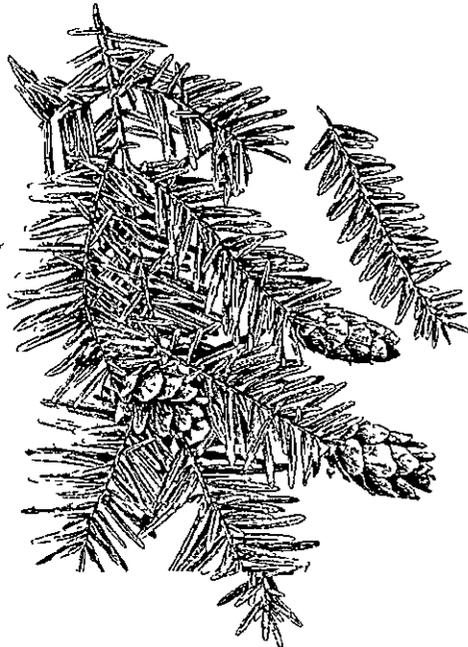

Protection

Implement an efficient fire protection program which is responsive to resource management objectives and prioritizes the protection of life, improvements, and private property.

Use prescribed fire to meet resource and land management objectives.

Protect Forest resources and facilities, and cooperate with State and local law enforcement agencies in the protection of visitors and protection of their property from theft, vandalism, or destruction.

Prevent or reduce losses due to insect and disease by treatment of vegetation to reduce the risk of epidemic outbreaks.

Research Natural Areas

Protect existing and nominated areas for the Research Natural Areas System to provide:

1. Baseline areas against which effects of human activities can be measured.
2. Sites for study of natural processes in undisturbed ecosystems.
3. Gene pool preserves for all types of organisms, especially rare and endangered types.

Diversity (Biodiversity)

Maintain representatives of native and desirable non-native plant and animal species and the plant communities in which they are found. Provide for all successional stages of terrestrial, aquatic and riparian plant associations in a distribution and abundance to accomplish this goal. Maintain or enhance ecosystem function to provide for long-term integrity and productivity of biological communities.

FOREST OBJECTIVES

The following table (Table 1) identifies the projected outputs associated with the decision to select Alternative C. As stated earlier, the actual outputs for individual years may vary from projected outputs due to fluctuations in conditions, funding, personnel, and priorities. Although the outputs are for a decade, each is expressed as an average annual value unless stated otherwise in the Table.

TABLE 1
RESOURCE OUTPUTS AND ACTIVITY SUMMARIES

Output/Activity	Unit of Measure	First Decade
<u>Developed Recreation Use</u>	Thousand RVD's/yr	3,140.9
Developed Site Construction or Reconstruction	PAOT	721
<u>Non-Wilderness Dispersed Recreation Use</u>

FOREST-WIDE STANDARDS AND GUIDELINES

The standards and guidelines are generally applied to measurable elements of the environment. They assist in meeting the above goals, objectives, and in achieving the desired future condition. See Chapter IV of the Forest Plan.

Standards and guidelines are included for:

Recreation
Lands
Wilderness
Facilities
Endangered, Threatened or Sensitive Species Protection
Wildlife and Fish
Timber
Riparian Areas
Water
Soil
Air
Rural Community and Human Resources
Minerals

MANAGEMENT AREAS

The Plan establishes management area prescriptions which apply to specific uses, resource considerations, natural features, or legislatively designated areas. The specific areas are mapped (see Alternative C maps depicting management areas) Specific standards and guidelines (prescriptions) have been developed for each management area.

EF-1 (Experimental Forest)

Provide opportunities to study the effects of forest management and fire on vegetative, soil, and water resources occurring on the east side of the Cascade Mountains. Maintain the area in a form that will not compromise the opportunities for research.

Objectives following the Entiat Burn in August 1970 were to study the effects of fire on complete hydrologic units.

EW-1 (Key Deer and Elk Habitat)

Manage deer and elk winter range to meet habitat requirements for sustaining optimum carrying capacity.

EW-2 (Riparian-Aquatic Habitat Protection Zone)

Maintain and enhance riparian management areas to perpetuate their distinctive resource values to (a) achieve and maintain habitat conditions necessary to maximize long-term natural production opportunities for desired fish species, (b) maintain water quality that meets or exceeds State Standards, and (c) provide diverse wildlife habitat.

EW-3 (Key Big Game Habitat/Unroaded)

Manage deer, elk, and mountain goat winter range and key summer range to meet habitat requirements for sustaining optimum carrying capacity in an unroaded setting

GF (General Forest)

Provide for long-term growth and production of commercially valuable wood products at a high level of investment in silvicultural practices.

MP-1 (Mather Memorial Parkway)

Manage area to maintain and enhance its outstanding scenic and recreation qualities.

OG-1 (Old-Growth Management)

Manage for old growth habitat to achieve "ecosystem diversity, preservation of aesthetic qualities," and/or "wildlife and plant habitat".

OG-2 (Mature Habitat)

Manage for mature to old growth habitat for wildlife and plant species dependent upon this habitat.

RE-1 (Developed Recreation)

Provide developed recreation in an Urban to Semi-Primitive Recreation Opportunity Spectrum (ROS) setting.

RE-2 (Dispersed Recreation, Unroaded, Motorized)

Provide dispersed, unroaded recreation in a semi-primitive motorized recreation opportunity setting.

RE-3 (Dispersed Recreation, Unroaded, Non-Motorized)

Provide dispersed recreation in an unroaded, semi-primitive, non-motorized or primitive setting.

RE-4 (Dispersed Recreation/Unroaded/Timber Harvest)

Provide for dispersed recreation, as well as long-term growth and production of commercially valuable wood products at a very low level of investment in timber cultural practices while maintaining the unroaded characteristics.

RM-1 (Intensive Range Management)

Provide for maximum forage production and utilization by commercial livestock with a high level of investment in range cultural practices.

RN-1 (Research Natural Areas)

Provide for: (1) Preservation of examples of all significant natural ecosystems for comparison with those influenced by man, (2) educational research areas for ecological and environmental studies, and (3) preservation of gene pools for typical and rare and endangered plants and animals.

SI-1 (Classified Special Areas-Scenic and/or Recreation)

Manage Special Areas for recreation use, substantially in their natural conditions.

SI-2 (Classified Special Area - Other)

Manage areas of significant cultural, geological, botanical, zoological, paleontological, or other special characteristics so as to protect, preserve, and enhance their intrinsic values

ST-1 (Scenic Travel - Retention)

Retain or enhance the viewing and recreation experiences along scenic travel routes.

ST-2 (Scenic Travel - Partial Retention)

Provide a near natural appearing foreground and middleground along scenic travel corridors

UC-1 (Utility Corridors)

Provide and manage utility corridors to accommodate energy transmission needs

WI-1 (Wilderness)

Preserve and protect the natural character for future generations, and provide opportunities for solitude, challenge, inspiration, and scientific study.

WS-1 (Proposed Scenic River)

Preserve the Scenic River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

WS-2 (Proposed Recreational River)

Preserve the Recreational River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

WS-3 (Proposed Wild River)

Preserve the Wild River characteristics of the river and surrounding area pending a decision on its legislative designation as part of the Wild and Scenic Rivers System.

The management area allocations for the Forest are summarized in Table 2. Objectives and desired future condition have been described by management area in Chapter IV of the Forest Plan. The FEIS, Chapter II and Appendix B describe the individual management areas in summary form. Also, see the Alternative C map.

Water		7,780

1/ Acres are distributed among other management areas adjacent to utility corridors

2/ All but 170 acres are within wilderness

MONITORING AND EVALUATION PROGRAMS

I adopt the monitoring and evaluation plans displayed in Chapter V of the Forest Plan. In summary, monitoring and evaluation are separate, sequential activities that provide information to determine whether programs and projects are meeting Forest Plan direction. Monitoring collects information, on a sample basis, from sources specified in the Forest Plan. Evaluation of monitoring results is used to determine the effectiveness of the Forest Plan and the need to either change the Plan through amendment or revision or to continue with the Plan.

The overall objective of monitoring and evaluating Forest Plans is to determine whether programs and projects are meeting Forest Plan direction. Within this broad objective, specific goals are to:

1. Ensure that Forest Plan goals and objectives are being achieved and management prescriptions are being implemented as directed.
2. Determine if the costs of implementing the Plan and the management effects are occurring as predicted.

There are three distinct levels of monitoring: (1) implementation monitoring; (2) effectiveness monitoring, and (3) validation monitoring. These levels are defined in FSM 1922 7.

Implementation Monitoring. Forest and Ranger District personnel will conduct implementation monitoring as part of their routine assignments and document the results in project files as part of their management responsibilities. Implementation monitoring will determine if the Plan, prescriptions, projects, and activities are implemented as designed and in compliance with Forest Plan objectives and standards and guidelines.

Effectiveness Monitoring. Effectiveness monitoring will determine if plans, prescriptions, projects, and activities are effective in meeting management direction, objectives, and the standards and guidelines. This level of monitoring will be conducted by resource and/or technical specialists on a limited basis as determined by resource values and risks, and public issues. Effectiveness monitoring will begin only after determining that the Plan, prescriptions, projects, or activities to be monitored have been implemented according to the Plan's direction

Validation Monitoring. Validation monitoring will determine whether the initial data, assumptions, and coefficients used in development of the Plan are correct; or if there is a better way to meet Forest planning regulations, policies, goals, and objectives. Validation monitoring will be conducted when effectiveness monitoring results indicate basic assumptions or coefficients are questionable. Generally, validation monitoring will establish permanent plots or studies in close coordination with research personnel. The scope of validation monitoring will be limited to those coefficients and standards that are not reasonably substantiated by existing research.

EVALUATION OF MONITORING RESULTS

Monitoring and evaluation are separate, sequential tasks. Monitoring is designed to observe and record the results of both natural processes and actions permitted by Forest Land and Resource Management Plans. Evaluation looks at those results, determines how well those results meet Forest Plan direction, and identifies measures to keep the Plan viable

Evaluation techniques include but are not limited to:

1. Site-specific observations by on-site resource specialists,
2. Field assistance trips by other technical specialists,
3. General field observations by Forest Service officials;
4. On-going accomplishment reporting processes;
5. Formal management reviews on a scheduled basis;
6. Discussions with other agencies and the public users,
7. Management team review of monitoring results;
8. Interdisciplinary team reviews of monitoring results;
9. Involvement with existing research activities, and
10. Review and analysis of records documenting monitoring results.

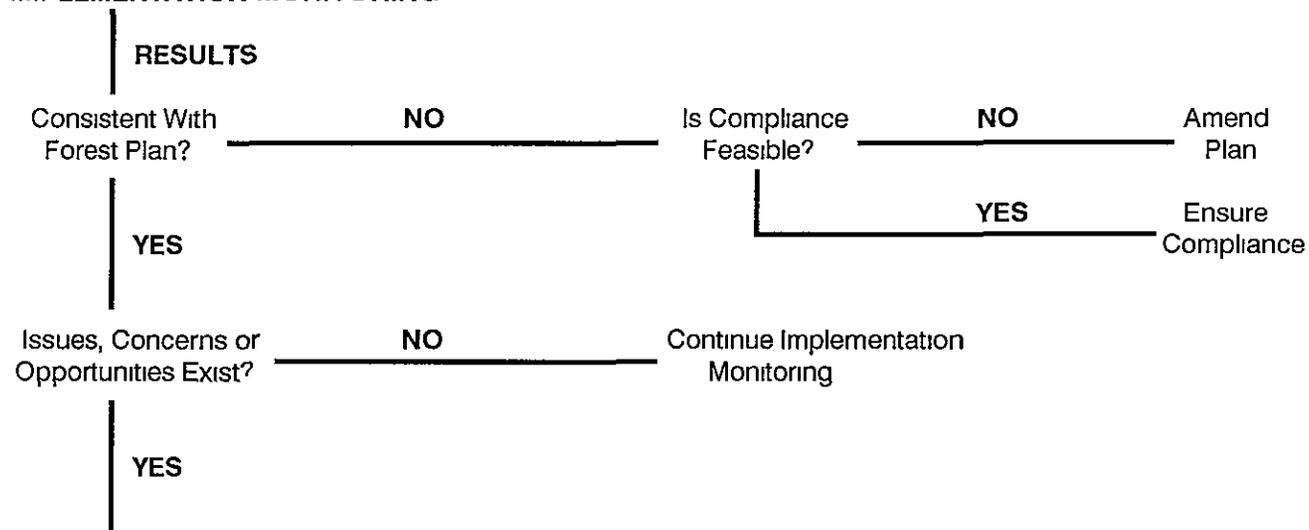

Evaluation in Relation to the Three Monitoring Levels Exhibit 1 displays the process for evaluating monitoring results from each monitoring level. There is a direct, sequential relationship between the levels. This relationship is designed to focus initial attention at the implementation monitoring phase. The approved Forest Plan represents the most appropriate, current management direction, therefore, we must first ensure that it is implemented as designed. Generally, needless expense and confusion may result by going directly to effectiveness or validation monitoring.

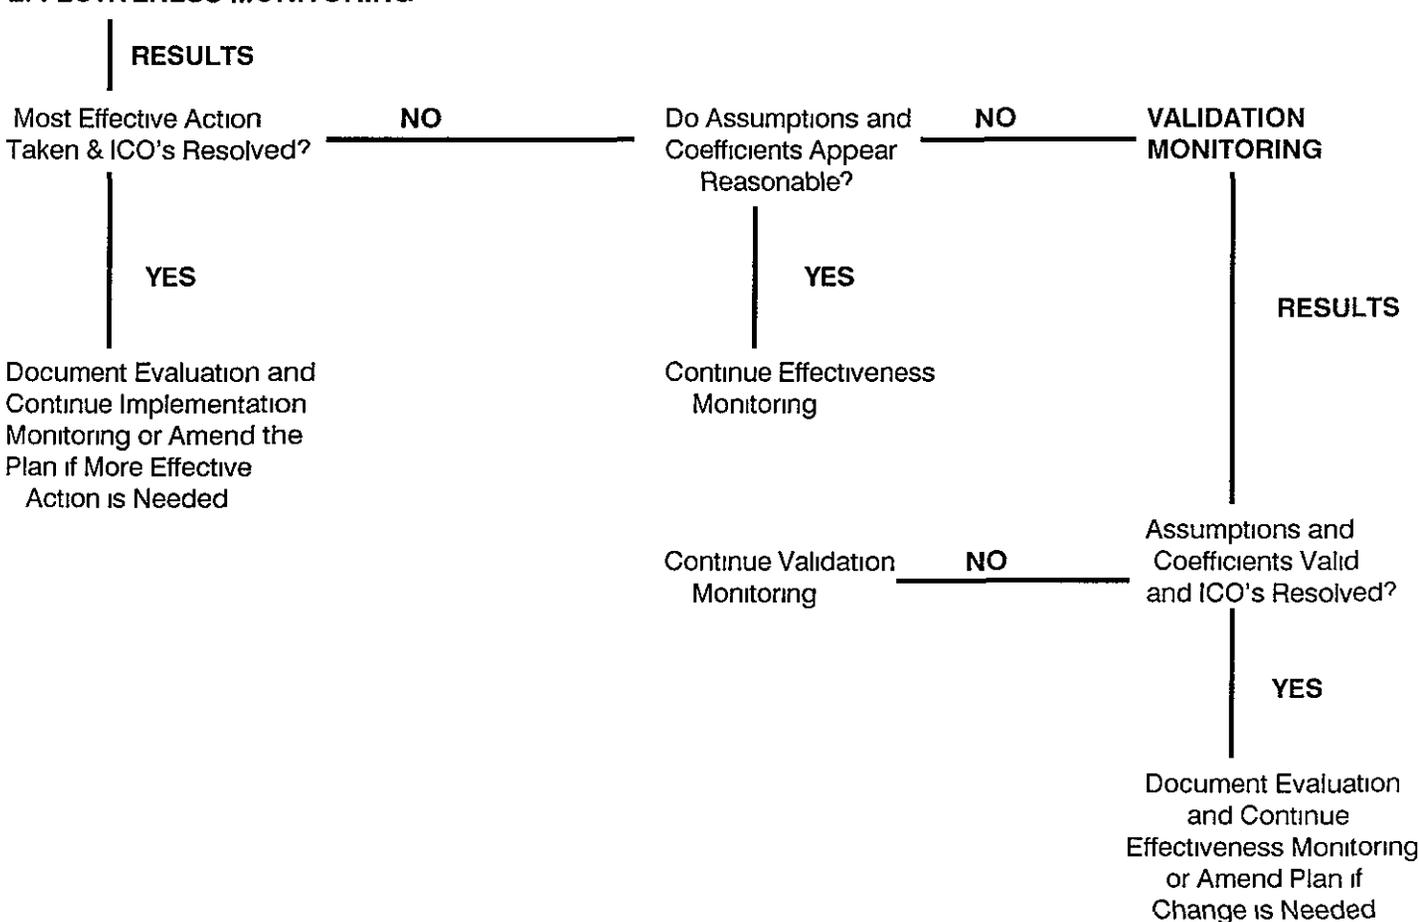

EXHIBIT 1

**EVALUATION OF MONITORING RESULTS
FOR FOREST PLAN IMPLEMENTATION**

IMPLEMENTATION MONITORING

EFFECTIVENESS MONITORING

III. RATIONALE FOR THE DECISION

The rationale for this program decision is presented two ways. First, I will discuss the rationale for resolving each issue. Second, I will compare integrated alternatives as a way of explaining my rationale for choosing the selected alternative.

Between the draft and final, the Forest had over 33 meetings with interested groups for the purpose of issue resolution. Initially, the Forest met with the various interest groups to listen to their concerns and clarify issues. Next, the Forest looked at alternative ways of addressing these concerns and developed a proposal for the major issues which they shared with the groups. Then, these groups gave the Forest feedback on these proposals which was used by the Forest to finalize their recommendation to me.

In arriving at this decision, I reviewed the environmental consequences of the Plan and the alternatives. I gave particular attention to the responsiveness of the selected plan to the public issues and management concerns identified in development of the Final Plan. In my judgment, Alternative C represents an equitable treatment of all resource considerations, and provides for both monetary and non-monetary outputs in a balanced and environmentally sound manner.

RATIONALE FOR RESOLVING EACH ISSUE

ISSUE 1: RECREATION OPPORTUNITIES AND USE CONFLICTS

The Forest receives about 5 million visitor days of use per year. Recreational use is continuing to increase and conflicts between recreational user groups (off-road vehicles or "ORVs", hikers, horses, snowmobilers, cross-country skiers) are becoming more common. In addition, recreation activities can cause resource damage because of the level, type, and location of use.

The preferred Alternative C of the DEIS emphasized continued ORV trail development and perpetuation of the existing land allocations allowing motorized and non-motorized use. Response to the DEIS indicated that the public is deeply divided on the appropriateness of motorized trail use in roadless areas of the Forest. A large number of respondents favored reductions in motorized trail use. On the other hand, ORV supporters were highly complimentary of the existing Forest program, saying it provides a unique recreation opportunity that is not met on other National Forests. Many trail users expressed a concern about the possibility of losing trail mileage as a result of timber management activities.

Between the draft and the final, the Forest initiated an intensive analysis of trail management, including semi-primitive motorized and non-motorized recreation opportunities, on the entire Forest, District by District, based on public comments to the DEIS and personal experience of professionals. The main purpose of the analysis was to find the proper balance between motorized and non-motorized trails for the Forest. A Forest Trail Management Statement was developed that outlined objectives, policy, and trail management criteria for this Forest-wide analysis. The Trail Statement included the following direction:

-The Wenatchee will provide a trail system that considers a diversity of use and the desire of users while caring for the land. Motorized use, bicycling, horse use and hiker use are all considered legitimate uses of the National Forest trail system.

-During the planning period, the emphasis will be placed on non-motorized use and the trail system will expand to meet increased demands from users.

-Motorized use will generally not be introduced onto trails or in areas where this type of use is not established.

-Trails "dead-ending" at the wilderness boundary should generally be closed to motorized use.

-The Forest will meet the direction given through Executive Order #11644 as modified by Executive Order #11989 which sets national policy for off-road vehicle use on the National Forests.

It is my decision to implement the standards and guidelines and management prescriptions relating to trail management in the selected alternative. This will result in several changes in trail use from the existing situation that will provide a proper balance of trail opportunities between motorized and non-motorized users and, hence, reduce the potential for conflict. Significant changes include closure of a major portion of the North Fork Entiat river drainage to motorized use, new trails for both motorized and non-motorized users, and protection of existing trail mileage. This results in a net increase of about 65 miles of motorized trails and a net increase of about 335 miles of non-motorized trails. Although not mandated by law or required by previous agreement, all trails that have been improved with Interagency Committee for Outdoor Recreation funds will remain open for motorized use.

The preferred alternative in the DEIS allowed timber harvesting in the Mather Memorial Parkway on the Naches Ranger District. Much of the public opposed this course of action and in response I developed a new management prescription for the Parkway. The new prescription enhances recreation opportunities in the area and limits scheduled timber harvesting to locations which are not visible from the Parkway or attendant recreation facilities. Harvest may also take place in the event of a catastrophe.

ISSUE 2: MANAGEMENT OF AREAS THAT ARE PRESENTLY UNDEVELOPED

There are twenty-three roadless areas outside of designated wilderness on the Forest. There are 556,272 acres within the roadless areas ranging in size from just under 5,000 acres to over 71,000 acres. These areas could be managed for roadless recreation such as backpacking or for roaded recreation such as vehicle camping. These areas can remain roadless to provide for the values associated with roadless areas or roaded to provide commodity values such as timber.

The preferred alternative of the DEIS proposed that seven of the twenty-three retain more than half of their area in a roadless condition. Out of 556,272 roadless acres the Draft preferred alternative proposed keeping 48% (267,610 acres) in a roadless condition.

The roadless areas are one of the major issues in development of the Forest Plan with 2,550 comments. Most of the comments favored preservation of all the roadless areas, while forest industry supporters stated that the Washington Wilderness Bill of 1984 released the roadless areas for multiple-use management. Off-road vehicle groups supported roadless area preservation because it raises the quality of their recreational experience. They mentioned the Manastash area the most frequently.

The Forest examined a range of alternatives that would maintain from 30 percent to 90 percent of the inventoried roadless area in a roadless condition. Also, the Forest reviewed specific comments for each roadless area and examined options for resolving concerns.

It is my decision to proceed with implementation of the selected alternative which directs that about 54 percent (298,115 acres) of the inventoried roadless area acres be maintained in a roadless character. The remaining 46 percent are allocated to various levels of development, which will result in roading and production of both commodities and amenities.

The additional areas to be managed as roadless respond to specific concerns that the public addressed in response to the DEIS, as well as continued concerns expressed since that time. Some specific places to be managed as roadless include the North Fork Entiat, Devil's Gulch, and Rock Creek.

All of the roadless areas on the Forest have been allocated and management activities will be proceeding in these areas according to their allocation. Proposed timber sales scheduled for roadless areas will receive appropriate environmental analysis and documentation before they are implemented. The existing roadless area allocations in the Alpine Lakes Management Unit

have been incorporated into the selected alternative and will continue to be managed as described in the Alpine Lakes Management Plan.

This decision will provide an equitable balance between preservation and development of the roadless areas.

ISSUE 3: TRANSPORTATION SYSTEM DEVELOPMENT AND MANAGEMENT

The Forest transportation system, including roads, trails, helispots, etc., is necessary for forest management, protection, and use. Presently there are 5,110 miles of roads and 2,463 miles of trail. Management of the transportation system is determined by the management direction for the various resources

Two facets of this issue were emphasized as a result of public comment on the DEIS: road management and the possibility of a road through Naches Pass.

The operation of the road system is of concern to some agencies such as the Washington Department of Wildlife. They contend that too many open roads can reduce habitat effectiveness for certain wildlife species. Implementation of the standards and guidelines for the selected alternative recognizes the value of road management for protection of wildlife. Newly constructed roads will be managed as closed to public vehicular access in most cases.

A private party applied for authorization to construct a road through Naches Pass in 1981. The Regional Forester, at the time, denied permission to build the road. The decision was based on the need to complete the Forest Plan and the land allocation process before a final decision on the roadway was made.

Almost all public comments received on the DEIS were in opposition to construction of the Naches Pass tie road. The private party that initiated the request for the Naches Pass road no longer needs it. Since the DEIS, the Forest has done further analysis to determine if a road across Naches Pass is needed for National Forest management purposes.

My decision makes it clear that a road across Naches Pass is not needed for purposes of National Forest management. A Naches Pass road is not planned by the Forest Service. It should be noted, however, that the land allocations in the area do not prohibit road development. Any public road agency or private party application will require site specific environmental analysis.

ISSUE 4: WATER QUALITY AND QUANTITY

The Forest currently produces more than 4.4 million acre feet of high quality runoff annually. The primary uses are for irrigation, downstream power generation, domestic consumption and aquatic and riparian habitat. Eastern Washington is a water-short area, with the Yakima River Basin having the most problems with supply. The preferred alternative for the DEIS set minimum water quality objectives for all the management areas on the Forest.

This issue received many comments concerning water quality, watersheds in general, timing of runoff, and irrigation. These comments were associated with harvest effects, grazing, sedimentation, and fisheries. Substantive comments on water were received from government agencies, tribal groups, and county commissioners. The standards and guidelines and management prescription direction for water in the selected alternative have been rewritten to respond to public comments.

It is my decision to implement revised standards and guidelines and management prescription direction for soil, water, fish and riparian areas. These standards and guidelines, including "Best Management Practices," will assure adequate protection for soil, water and riparian dependent resources.

ISSUE 5: MIXED OWNERSHIP MANAGEMENT

Land within the Forest boundary totals 2,457,379 acres. Of this, about 12 percent is managed by the Bureau of Land Management, Washington State, and private landowners. Much of this land is scattered throughout the Forest and occurs in "checkerboard" patterns in the Interstate 90 and Highway 2 corridors. Management philosophies, practices, and goals of other owners sometimes differ from those of the Forest Service. This can directly affect management options on National Forest land, influencing roading decisions, timber harvest scheduling, and scenery.

The preferred alternative of the DEIS established priorities for acquisition and areas suitable for exchanging into private ownership.

In general, public comment supported acquisition of private land in mixed ownership situations. However, there was strong opposition to Wild and Scenic River designation because of the possibility of acquiring private land.

It is my decision to implement the standards and guidelines and management prescription direction for all land adjustment activities found in the selected alternative. There does not appear to be a need to acquire private land within the river corridors that I am recommending for inclusion into the Wild and Scenic River System with one exception. A 200 foot strip of right-of-way may be needed to provide public access to the Wenatchee river near Plain.

ISSUE 6: WILDERNESS MANAGEMENT

The Forest has 841,034 acres classified as wilderness, amounting to about 39 percent of the land area. There are portions of seven wildernesses on the Forest ranging in size from the 36,316 acre Goat Rocks Wilderness to the 289,001 acre Glacier Peak Wilderness. Unlike some wildernesses, which have shown dramatic declines in use, the Wenatchee wildernesses continue to experience increases in use. User conflicts between horse users and hikers and resource protection problems are occurring more frequently

Although public comments on wilderness were relatively few, I have decided to implement the standard and guidelines and management prescription detailed in the selected alternative. This management direction is needed to assure that overuse and unacceptable resource damage do not occur. All of the wilderness on the Forest has been allocated to the following Wilderness Recreation Opportunity Spectrum classes: pristine, primitive, semi-primitive, or transition. Each of these classes has specific management direction that is intended to protect its attributes. Special monitoring using the "limits of acceptable change" method will assure adequate protection of the wilderness on the Forest.

ISSUE 7: WILDLIFE AND FISH

The Wenatchee sustains a wide variety of fish and wildlife species because of its diversity of habitats. Management activities that affect fish and wildlife habitat are timber harvest, recreation, livestock grazing, road management, and fire management. The major wildlife issues on the Forest are with management indicator species such as spotted owl, big-game species, and anadromous fish habitat.

The preferred alternative of the DEIS addressed mature/old growth dependent wildlife species, including spotted owls, in a management prescription which allowed for some timber harvest. Public comments to the DEIS indicated that many people disagreed with our proposal to "manage" mature/old growth habitat through timber harvest. They thought that it would be impossible to retain the necessary characteristics of old growth ecosystems while allowing timber management. Comments from timber industry questioned the requirements of our indicator species to have old growth. They stated that spotted owls and pine marten are found in managed or second growth forests and, therefore, no old growth is needed outside wilderness and other areas identified for preservation.

Between the Draft and Final, a Supplemental Impact Statement was issued by the Pacific Northwest Region of the U.S. Forest Service. The analysis in this document considered the conflicting views and scientific information of others. It provided new criteria for establishing "Spotted Owl Habitat Area" (SOHA) networks on forests in Washington and Oregon, including the Wenatchee National Forest. While the Draft EIS considered a total of 1,700 acres for each SOHA on the Forest, with 300 acres dedicated and 1,400 acres managed, the SEIS required that the Forest either dedicate 2,200 acre SOHA's or manage for 4,100 acre SOHA's

Recently, the U.S. Fish and Wildlife Service proposed listing the Spotted Owl as threatened in the range of the northern subspecies which includes the Wenatchee. Results of this listing process will be used to make appropriate adjustments to the Plan.

It is my decision to adopt a spotted owl habitat network that meets the direction given in the SEIS. Complying with this direction, which is included in the standards and guidelines of the selected alternative, assures continued viability of the spotted owl and other mature/old growth dependent wildlife species.

The spotted owl network consists of dedicated "Spotted Owl Habitat Areas," suitable habitat in wilderness, and other suitable habitat in management areas not allowing a scheduled timber

harvest. The selected alternative will maintain about 353,000 acres or about 68 percent of the 521,000 acres of known suitable spotted owl habitat on the Forest. This network is well distributed throughout the Forest and takes into account both suitable habitat and location of known spotted owls. Refer to "Compatibility With Other Agency Goals and Plans" section for further discussion of Spotted Owl direction.

The Spotted Owl network will also be utilized by the following indicator species: pine marten, three-toed woodpecker and pileated woodpecker. In addition, about 49,000 acres will be managed as "mature" on a 180-year rotation to round out the habitat distribution for these species.

Big game such as deer, elk, and mountain goats make up an important component of wildlife diversity on the Forest. The preferred alternative to the DEIS contained standards and guidelines as well as management prescriptions addressing big game. Although many public comments of a general nature favored the preservation of wildlife, some groups felt that we had more restrictive requirements for timber harvest in deer and elk winter range than was necessary. The Forest analyzed the 260 year timber rotation for deer and elk winter range and found it to be unnecessary. Winter range cover requirements can be met with a 120-130 year rotation.

It is my decision to adopt a 120-130 year rotation requirement for deer and elk winter range. There appears to be no scientific basis for an extended rotation and the same wildlife benefits can be achieved by providing thermal cover on a shorter 120-130 year rotation.

The Forest has about 3,600 miles of perennial streams and 57,000 acres of lakes. Many of these streams and lakes support an anadromous and/or resident fishery. Indian tribes and other agencies felt that our preferred alternative standards and guidelines in the DEIS were inadequate to protect fish habitat. Since that time, the Forest has continued to analyze this issue and talk with concerned Indian tribes and other agencies.

It is my decision to implement a significantly revised set of standards and guidelines and management prescriptions in the selected alternative that will provide for the assurance of contin-

ued high quality fish habitat in the future. The Draft standards and guidelines were stated in general qualitative terms. The new quantitative standards and guidelines in the Final set forth measurable parameters for sediment, temperature, channel morphology and flood plain/riparian vegetation. This will allow the Forest to monitor the environmental impacts of management practices more accurately. In addition, I am implementing an accelerated stream/watershed survey program to assess current habitat conditions.

During the past couple of years, Forest and Regional Offices in Regions 1, 4, and 6 have been working closely with Columbia Basin Indian tribes and the Columbia River Inter-Tribal Fish Commission on the issue of anadromous fish habitat management. At this time, a Forest Service draft policy and policy implementation guide have been developed, and are expected to be approved in the near future. Upon approval of the policy and implementation guide, the Forest Plan will be reviewed and amended if necessary as soon as it is practicable to do so. I believe this policy will be an important factor in helping to achieve a mutual goal of the Tribes and Forest Service to provide strategies for habitat management and anadromous fish production consistent with fish restoration goals of the Columbia Basin Fish and Wildlife Program.

ISSUE 8: MANAGEMENT OF SCENERY

The Wenatchee National Forest is well known for its outstanding mountain, valley, and lakeshore scenery. The landscapes are distinctive in beauty and nature, with sweeping vistas and a variety of topography, ecotypes and life forms.

The public comment on the DEIS showed strong public support for a natural appearing forest, especially along major travel routes such as Stevens and Blewett Passes. Comments from forest industry contended that prescriptions for scenery were too strict.

It is my decision to maintain the scenic qualities along major forest travel routes and particularly roads leading to developed recreation sites or other major facilities. The standards and guide-

lines and management prescriptions for the selected alternative will maintain about 78 percent of the Forest in a natural or near natural appearing landscape over time.

ISSUE 9: TIMBER MANAGEMENT

The existing Timber Management Plans are tracked and controlled on board foot measure. They allow for an annual programmed timber harvest of 176.8 million board feet (MMBF). This includes about 14 MMBF for salvage purposes and about 6 MMBF marginal component (see FEIS Glossary), leaving about 157 MMBF of net green sawlog volume, which is comparable to the "allowable sale quantity." The actual annual harvest has been about 157 MMBF of net green volume for the last 13 years. The DEIS proposed an allowable sale quantity of 129.7 MMBF (23.8 MMCF).

The allowable sale quantity will be tracked and controlled on a cubic foot measure for the Forest Plan. The board foot volume associated with the cubic foot volume (i.e., board foot/cubic foot conversion ratio) varies from stand to stand depending on the size and form of the trees. Both approximate board foot measure and cubic foot measure are displayed here, since board foot has been and continues to be the predominate unit of measure in the area.

Many of the issues raised during the planning process affect the allowable timber harvest level. Some of these issues include cumulative effects, tentatively suitable lands, silvicultural practices, meeting other resource standards and guidelines, and trade-offs between present net value and harvest level. The public is divided as to what the appropriate timber harvest level should be on the Wenatchee. Some feel that the existing timber harvest level is too high. They do not want to see existing unroaded areas roaded and are concerned about the harvest effects on wildlife, water quality, soils, scenery, and recreation. Forest industry, most County Commissioners, and some Chambers of Commerce feel that there is enough wilderness and that the roadless areas outside wilderness should be developed.

Timber industry submitted an alternative calling for an annual allowable sale quantity of 180 MMBF (35.3 MMCF) The Forest thoroughly analyzed the alternative presented by timber industry and made a number of FORPLAN computer runs to finalize the allocations and attempt to meet the 180 MMBF (35.3 MMCF) requested. This alternative has been included as a fully developed alternative in the FEIS. It is known as Alternative "J" and produces an allowable sale quantity of about 173.8 MMBF (34.1 MMCF). When compared with selected Alternative C, this alternative produces significantly less roadless area acreage, reduced scenic quality, and much less present net value. This is contrary to the amenity values that are of concern to a large segment of the public. See Table 4 for specific information.

The Forest considered alternatives ranging from an allowable sale quantity of 12.9 MMCF (71.9 MMBF) to 34.1 MMCF (173.8 MMBF) in the FEIS. It should be noted that the DEIS considered a range of alternatives from 13.6 MMCF (74.1 MMBF) to 34.3 MMCF (186.9 MMBF). The difference in the range of alternatives between the DEIS and FEIS reflects the reduction in the capability of the Forest to produce timber due to implementation of the requirements of the Supplement to the EIS for an Amendment to the PNW Regional Guide regarding Spotted Owls.

Because of concerns raised by timber industry in response to the DEIS, the Forest further analyzed suitability, growth and standing inventory volume, programmed more intensive timber management practices to improve tree growth and removed the commercial thinning constraint from the FORPLAN model. These modifications were completed as recently as 1988 and 1989. They allowed an increase in allowable sale quantity from the amount in the DEIS preferred alternative (FEIS Appendix B). We will continue to update our data base during implementation and make adjustments to allowable sale quantity if the new information justifies it. See related discussion in AMENDMENT AND REVISION PROCESS.

Purchasers of Wenatchee National Forest timber depend on the Forest for approximately 60 percent of their timber supply needs. The Plan assumes that demand for all the timber the Wenatchee produces will continue to exist. But,

the Forest cannot produce more than the selected Allowable Sale Quantity and still meet the other resource requirements.

On October 5, 1989 timber industry filed suit in the U.S. District Court for Eastern District of Washington seeking Declaratory and Injunctive relief. On December 6, 1989 the Court denied Plaintiff's requested relief and dismissed the Complaint without prejudice on grounds of lack of ripeness for judicial review and failure to exhaust administrative remedies.

After considering all factors, it is my decision to implement the selected alternative calling for an allowable sale quantity that averages 24.3 MMCF (136.0 MMBF) per year. This level of timber harvest strikes an equitable balance between jobs, demand for wood products, income to the Treasury and protection of the various amenity values enhancing the quality of life for Forest users.

In addition to the 24.3 MMCF (136.0 MMBF) of sawlogs, it is expected that there will be about 1.8 MMCF (10.0 MMBF) of material unsuitable for sawlogs that will be sold each year. This material includes firewood, cull logs, small logs, and miscellaneous forest products such as fence posts and poles. This is about the same as the historical level of output for these products.

Many comments to the DEIS expressed a dislike for the clearcutting method of timber harvest. The Forest looked at alternatives ranging from about 600 acres per year to over 8,000 acres per year. In the past, the Forest used this method of harvest on an average of 3,000 to 4,000 acres per year. The selected alternative predicts that this practice will be used on about 3,400 acres per year, or about 40 percent of the area entered for timber harvest. However, the decision on the most appropriate method of timber harvest will be made on an individual timber sale project basis in compliance with NFMA and standards and guidelines of the selected alternative.

Refer to Issue 16 for further discussion of timber-related issues.

ISSUE 10: ENERGY

An adequate supply of energy, as well as its conservation, is a high priority national objective. Forest lands play an important role in the production and transmission of energy. These include coal, hydroelectric power, oil and natural gas, geothermal, and renewable forest products.

In the preferred alternative of the DEIS, this issue dove-tailed with the minerals issue. The standards and guidelines and management prescriptions covered both mineral development and energy development. The Draft preferred alternative also identified energy corridors for current and future transmission lines.

There were few public comments on this issue. It is my decision to implement the selected alternative with the standards and guidelines and management prescription direction for energy. These standards and guidelines will adequately protect the environment while allowing for necessary development and use to help meet the foreseeable energy needs of the region.

ISSUE 11: THE ROLE OF FIRE

Although fire has long been considered an enemy of the forest, it has always been a natural and integral component of the ecosystem. It helps shape much of the habitat which many species need to survive. While fire suppression efforts are necessary, a total exclusion of fire from the forest ecosystem can result in adverse effects such as unnaturally large build ups of fuels which can lead to larger and more intense fires in the future.

Under properly controlled circumstances, fire can often benefit wildlife habitat, silviculture and recreation by recycling nutrients back into the soil and invigorating certain plant species. Prescribed fire can, at times, conflict with the requirements of the Clean Air Act and the views of some sectors of the public.

It is my decision to allow the use of prescribed fire forest-wide to enhance resource values and reduce the risk of catastrophic wildfires. This decision includes allowing naturally caused fires in

designated wilderness to burn only within tightly drawn constraints as set forth in detailed fire management plans. These fire management plans shall spell out very limited circumstances which must occur before a naturally caused fire will be allowed to burn. If, after close monitoring, the fire threatens to exceed those parameters, then immediate steps to suppress the fires shall be taken

ISSUE 12: RANGE MANAGEMENT

Livestock grazing presently takes place on the Forest through grazing permits issued to 37 livestock owners. Within the Forest, there are 401,100 acres within vegetation types and on slopes suitable for grazing by livestock. There are an additional 500,871 acres outside wilderness potentially capable of livestock forage following timber harvests. The current management potential of the Forest to provide forage for livestock has been calculated at 37,031 animal unit months (AUM's) annually. Current permitted livestock use is 23,000 annually. Current demand is also 23,000 AUM's annually.

Livestock grazing has the potential to conflict or complement other resources. The Forest received a large number of general comments opposing increased grazing. There was concern expressed over preservation of sensitive native plants, conflicts with big game, and subsidizing individuals holding grazing permits.

The preferred alternative of the DEIS showed an expected permitted use of 22,000 AUM's annually for the first decade, 25,500 AUM's annually for the second decade, and 36,000 AUM's annually for the fifth decade.

It is my decision to limit livestock grazing to 23,000 AUM's annually for the first decade, which corresponds to the expected demand. Grazing will be confined to existing allotments. In addition, I have updated the management prescriptions and standards and guidelines to insure that livestock grazing does not conflict with sensitive native plants and big game.

ISSUE 13: MINERALS

This issue is closely related to the energy issue. Mineral resource activities in the central part of the Wenatchee National Forest took a dramatic upturn in March 1983 following a major gold discovery in Dry Gulch, a few miles off the Forest near the city of Wenatchee. This triggered the location of more than 6,000 claims on National Forest land in Chelan County and at least 1,000 claims in Kittitas County. This claim activity is continuing today with finds of another potential mine site close to the Forest. The basic issue is how much of the potential mineral lands will be allocated to uses that prohibit or severely limit exploration and mining opportunities.

The preferred alternative for the DEIS set direction for mineral development and exploration over the Forest and more specific direction for each management area.

The public comment showed concern over the term "highly restricted" in the DEIS and the possible impact of the proposed plan on recreational mining. Other individuals were concerned about the impact of mineral development on other resources.

The document has been changed to clarify the situation as to mineral development and recreational mining. It is my decision to implement the standards and guidelines and management prescription direction for minerals. This will provide for mineral development and recreational mining on appropriate lands while protecting other resources such as fisheries and water quality.

ISSUE 14: CULTURAL RESOURCE MANAGEMENT

The Wenatchee National Forest contains over 500 cultural resource sites (archeological sites, historic structures, etc.) that have been reported within or adjacent to the Forest. Those sites represent a broad cross-section of uses, spanning a period of several thousand years. A central concern is to provide a balance between these other uses and the protection of cultural sites so as to provide adequately for their preservation.

The preferred alternative of the DEIS provided forest-wide standards and guidelines and specific direction for each management area for cultural resources. There was some concern by some members of the public whether the forest has adequate staffing to implement the proposed guidelines.

It is my decision to implement the standards and guidelines and management prescription direction for cultural resources and I expect these measures to be adequate to mitigate any adverse effects to significant sites due to project activities.

ISSUE 15: CUMULATIVE EFFECTS

Cumulative effects are the collective long-term environmental impacts which result from natural processes and human activities on the land. For the Wenatchee National Forest the principal area of concern is the cumulative impacts of timber harvest activities on watersheds, fish, and wildlife. Other areas of concern are cumulative effects on scenery and recreational resources. The DEIS covered the direct, indirect, and cumulative effects of alternatives.

The public comments dealt mostly with cumulative effects of management activities on soil and water. There was concern that the DEIS did not effectively consider cumulative effects. This issue is directly tied to other issues such as intermingled ownerships, fish and wildlife, scenery, recreation, water quality, and timber harvest.

I have completed a cumulative effects analysis on selected watersheds. Changes in timber harvest scheduling were made to reduce the risk of watershed degradation in appropriate cases. It is my decision to do a detailed cumulative effects analysis on sub-drainages whenever it is an issue or whenever more than 40 percent of the forested area in a 1,000 acre or larger sub-drainage is in openings less than 15 feet in height, and new projects are proposed in the area. The detailed watershed analysis will be considered at the time of site specific project environmental analysis, as appropriate, to meet NEPA requirements and standards and guidelines in the Forest Plan. This will protect water quality, fish and wildlife, recreation, and scenery resources.

ISSUE 16: SOCIAL/ECONOMIC

The central Washington area consisting of Yakima, Kittitas, and Chelan Counties covers 9,503 square miles with a population of 270,000 people. Residents are affected by the Forest through availability of recreation, payments to county governments from Forest receipts, production of market goods such as lumber and beef, and other amenities such as enjoyment of the visual character of the forest. Economic activities affecting local individuals include logging, sawmill operations, commercial livestock operations, tourism, and various recreational pursuits. The Forest is a couple of hours drive from the Puget Sound area and is an important recreation area for its residents.

The preferred alternative of the DEIS proposed a decrease in allowable sale quantity from 28.7 MMCF (156.8 MMBF) to 23.8 MMCF (129.7 MMBF). There was an increase in amenity values such as roadless areas, old-growth wildlife habitat areas, big-game winter range, and scenic areas.

The public comments from the Seattle area generally supported increased amenity outputs. The public input from central Washington was split, with those who work in the forest products industry calling for a higher harvest level than proposed in the DEIS. Others in central Washington that lived in tourist-dependent communities or in the larger towns supported increased amenity outputs.

As noted under the timber management section, it is my decision to implement an allowable sale quantity of 24.3 MMCF (136.0 MMBF) in the selected alternative. Even though this is a substantial drop from the volume that could be sold under the existing Timber Management Plan, the selected alternative meets the intent of the National Forest Management Act requirements while the existing Timber Management Plan pre-dates NFMA. Alternative A/NFMA, which maintains current management for the Forest and meets the requirements of the National Forest Management Act produces 21.8 MMCF (121.4 MMBF)

In response to economic concerns the Forest looked for ways to increase the harvest level while meeting public expectations regarding amenities and adequate resource protection. The selected alternative helps protect jobs and receipts to counties as well as amenity values that are of concern to a large segment of the public.

Decisions contained in the Forest Plan will affect communities. The Forest Service will work with communities to address these effects within the framework of the Pacific Northwest Strategy.

ISSUE 17: OLD GROWTH

Old growth means different things to different people. To some, old growth provides habitat for certain wildlife species. To others, old growth provides a spiritual and aesthetic experience. Old growth can also provide examples of relatively undisturbed ecosystems. For others, old growth provides a source of high quality wood.

The Wenatchee used the Forest Service definition for Old Growth found in the Regional Guide, "An Old Growth stand is defined as any stand of trees 10 acres or greater generally containing the following characteristics: stands contain mature and overmature trees in the overstory and are well into the mature growth stage; stands will usually contain a multilayered canopy and trees of several age classes; standing dead trees and down material are present; and evidence of man's activities may be present, but does not significantly alter the other characteristics and would be a subordinate factor in a description of such a stand..." (Regional Guide page A-11).

The analysis in the DEIS focused on provision of old growth for old growth dependent wildlife species such as spotted owl. Though the other values of old growth were taken into account, the discussion of old growth was limited to wildlife species.

Old growth was one of the major issues based on the number of public comments with responses generally more emotional than on other issues. Most wanted preservation of existing old growth. In the minds of many people this issue was closely tied to roadless area preservation.

The discussion in the FEIS has been expanded to include other facets of the old growth issue besides wildlife. The amount of existing old growth, according to the Regional Guide definition, is about 318,800 acres including about 148,500 acres in wilderness and 63,700 acres in "no harvest" allocations. It should be noted that the planned rate of cutting of old growth will allow changes if the public places more or less value on old growth in the future. For instance, about 307,300 acres or 96 percent of the existing old growth will remain after the first ten years of plan implementation. Even after 50 years of implementation, about 261,200 acres or about 83 percent will remain. The old growth inventory will be updated and refined as new data becomes available. It is my decision to implement the standards and guidelines and management prescription direction for old growth for the selected alternative.

ISSUE 18: WILD AND SCENIC RIVERS

In October 1968, Congress enacted the Wild and Scenic Rivers Act which established the Wild and Scenic Rivers System. The criteria for eligibility are that the rivers be free-flowing and possess one or more outstandingly remarkable, scenic, recreational, geologic, fish and wildlife, historic, cultural, or ecological values.

The DEIS, released in 1986, considered seven rivers and recommended three for further study and possible inclusion into the Wild and Scenic Rivers system. In response to the DEIS, the public recommended numerous additional rivers

for possible inclusion into the National Wild and Scenic River system. Also, some of the public wanted some rivers within wilderness to be formally classified. No input from landowners was received in response to the Draft.

As a result of the public comment, the Forest studied 20 rivers totalling about 470 miles for eligibility. Nine of these rivers were determined to be eligible. The suitability study recommended eight rivers for inclusion in the system in a Supplement to the DEIS that was released in October 1988.

1988
DEIS

Some respondents to the Supplement liked the Wenatchee's proposal, others wanted additional rivers proposed that the Forest had said were ineligible or not suitable and still others, including most landowners and County Commissioners, felt that no rivers should be included in the Wild and Scenic River System and that personal rights and local control of the rivers were more important than Federal regulation, particularly on private lands.

In response to public comments, the Forest studied yet an additional 13 rivers for eligibility and reexamined those ineligible rivers addressed by the public. As a result, the Wapatus River was determined to be eligible and suitable for "wild" classification. In addition, the Forest seriously reviewed eligible rivers with private lands along their banks to determine how to respond to landowner and County Commissioners' concerns including appropriateness of County zoning and need for acquisition of easements. Our recommendation on classification correlates closely with State laws and County zoning.

FEIS

The analysis the Forest has done is adequate; it is my decision to recommend nine of the ten eligible rivers, totalling about 230 miles with their attendant classifications, for inclusion into the Wild and Scenic Rivers System without further study. A list of recommended rivers and their classifications follows:

		Cumulative #		
		considered	eligible	suitable
1986	DEIS	7	-	-
1988	DEIS Supp.	20	9	8
1990	FEIS	33	10	9
				31

1986
DEIS

NINE SUITABLE RIVERS

River	Recommended Classification	Miles	Segment
American	Wild	6.0	Headwaters to confluence with Rainier Fork
	Scenic	16.0	Confluence with Rainier Fork to confluence with Bumping River (in Mather Memorial Parkway corridor).
Chiwawa	Wild	5.0	Headwaters to Glacier Peak Wilderness boundary
	Recreational	24.0	Glacier Peak Wilderness boundary to Goose Creek
	Recreational	6.0	Goose Creek to confluence with Wenatchee River
Cle Elum	Wild	4.0	Headwaters to Alpine Lakes Wilderness boundary
	Scenic	2.0	Alpine Lakes Wilderness boundary to above Lake Tucquala
	Recreational	14.0	Above Lake Tucquala to Salmon La Sac bridge.
	Recreational	4.5	Salmon La Sac bridge to Lake Cle Elum.
Entiat	Wild	12.5	Headwaters to Glacier Peak Wilderness boundary
	Scenic	4.0	Glacier Peak Wilderness boundary to Cottonwood Trailhead
	Recreational	15.0	Cottonwood Trailhead to above Burns Creek
Icicle	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary.
	Recreational	14.0	Alpine Lakes Wilderness boundary to above Leavenworth city water intake.
Napeequa	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary
	Recreational	1.0	Glacier Peak Wilderness boundary to confluence with White River
Waptus	Wild	12.0	Headwaters to Alpine Lakes Wilderness boundary
	Wild	1.0	Alpine Lakes Wilderness boundary to confluence with Cle Elum River.
Wenatchee	Recreational	21.0	Lake Wenatchee to Tumwater Campground
	Recreational	7.0	Tumwater Campground to Forest boundary
White	Wild	15.0	Headwaters to Glacier Peak Wilderness boundary.
	Scenic	7.0	Glacier Peak Wilderness boundary to above Tall Timbers Ranch
	Recreational	12.0	Above Tall Timbers Ranch to Lake Wenatchee

This decision recommends many of the rivers with private lands at less than their highest potential classification. It is my intent that the Forest work with county governments and utilize State and local controls for administration of private lands within the designated river corridors as much as possible. Appendix E of the FEIS contains additional guidelines for developing future detailed river management plans in line with this decision.

I have determined that the Little Wenatchee river is not suitable for inclusion into the Wild and Scenic river system, even though it is eligible, because of the value of other resources. I believe that the outstandingly remarkable value, the sockeye salmon, can be effectively managed through other management prescriptions and standards and guidelines.

This recommendation is a preliminary administrative recommendation that will receive further review and possible modification by the Chief of the Forest Service, Secretary of Agriculture, and the President of the United States. The Congress has reserved the authority to make final decisions on designation of rivers as part of the National Wild and Scenic Rivers System. Recommended rivers will be managed to protect those characteristics that contribute to the eligibility of these rivers at their highest potential classification until Congress formally determines their status.

RATIONALE FOR ALTERNATIVE SELECTION

ALTERNATIVES CONSIDERED

In the DEIS, including the supplement, ten alternatives were analyzed and presented in detail. In addition, 14 benchmark alternatives were developed and utilized in the analysis process. The benchmarks served as analysis reference points to define bounds for comparison purposes only. They were not developed with the intent of being implemented. In the FEIS, 11 alternatives are analyzed in detail, including an alternative submitted by the timber industry, Alternative J.

The Current Direction Benchmark with National Forest Management Act (NFMA) is now Alternative A/NFMA in the FEIS

Summary Description of Final Alternatives

Alternative A/NFMA

This is the No Action Alternative. It was formulated to maintain the current management direction for the Forest. Sources of that direction were the Alpine Lakes Management Plan, the Chelan and Kittitas Unit Plans, and the Ranger District multiple use plans. Alternative A/NFMA portrays how these plans would influence the flow of goods and services over the life of this plan (10-15 years) based upon the use of current National Forest Management Act of 1976 (NFMA) planning data.

This alternative has been corrected from the DEIS version (Alternative A) and meets all NFMA requirements as explained in the "Correction and Supplemental Information" which was included with the Reviewer's Guide when the DEIS was mailed to the public. The Supplement to the DEIS also contained corrected information and displayed this alternative as Alternative A/NFMA. Essentially the difference between Alternative A in the original DEIS and Alternative A/NFMA is that this alternative now meets all of the NFMA management requirements including protection of habitat for wildlife dependent upon old-growth and mature habitat types.

One of the features of this alternative is that it contains significantly fewer acres of EW-1 (Key Deer and Elk Habitat) than any of the other alternatives except the No Change Alternative. The reason for this is that most of the existing plans did not contain specific allocations for key deer and elk habitat.

The major changes in this alternative from the DEIS and the Supplement to the DEIS include:

Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS, and “dedicating” old growth spotted owl habitat areas rather than “managed” old growth.

Alternative B

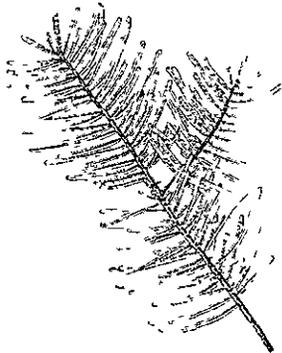

This alternative was developed in an attempt to meet the 1980 Resources Planning Act program which has been assigned to the Forest through the Regional Guide.

The 1980 RPA timber target strongly influenced our approach. This alternative uses the Alternative D land allocations. It portrays the Forest’s second highest timber producing capability while considering other resource needs. This alternative would result in the greatest amount of development of the Forest.

A feature of this alternative and Alternative D is the higher allocation to General Forest (GF) and a corresponding decrease in the unroaded and scenic travel allocations compared to most other alternatives except Alternative J. The major difference between this alternative and Alternative D is that in Alternative B more intensive timber management will be practiced on the General Forest land allocation which will result in higher yields and higher annual sale quantities

The major changes in this alternative from the DEIS and the Supplement to the DEIS include

Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and “dedicating” old growth spotted owl habitat areas rather than “managing” old growth.

Alternative C

This alternative was developed by adjusting the current direction (Alternative A/NFMA) to a land allocation which would maximize net public benefits and would provide a balanced program in response to the issues and concerns. The purpose of Alternative C is to respond to concerns for protecting wildlife and other amenity resources and provide a variety of recreation opportunities while managing the Forest for commodity outputs. This was accomplished by modifying existing plans and practices to respond to public concerns received during issue identification early in the planning process. Further modification of this alternative has been done to respond to comments received through the public response on the Draft EIS and Supplement to the DEIS

Another way Alternative C differs from Alternative A/NFMA is that it allocates many more acres to key big game range and increases the acreage allocated to roadless management

The major changes in this alternative from the DEIS and the Supplement to the DEIS include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and “dedicating” spotted owl habitat areas rather than “managing” them.
- Increase inventoried roadless area acreage from 267,610 acres to 298,115 acres.
- Development and application of the Mather Memorial Parkway prescription (MP-1) which allows only unscheduled timber harvest within the seen area of the Parkway corridor
- An addition of two new allocations: EW-3 (Unroaded Wildlife) and RE-4 (Unroaded Harvest).
- Changes in the classification on some of the recommended Wild and Scenic Rivers, and the addition of the Waptus River to those recommended for designation
- Increase in acreage of Special Interest Areas
- Increase in the allowable sale quantity of timber by the use of intensive timber management practices on more acres.

Alternative D

This alternative emphasizes production of resources such as timber, range forage, developed recreation, minerals, and other resources which have the potential to return revenue to the Federal Treasury and local counties. Management of other resources is at economically and environmentally feasible levels consistent with the emphasis on market oriented outputs

A feature of this alternative and Alternative B is the higher allocation to General Forest (GF) and a corresponding decrease in the unroaded and scenic travel allocations. The major difference between this alternative and Alternative B is the economic emphasis. This results in less intensive timber management on the GF land allocation and a lower annual sale quantity with an increased present net value compared to Alternative B.

The major changes in this alternative from the DEIS and the Supplement to the DEIS include.

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.

Alternative E

This alternative allocates all currently roadless areas outside of the existing wilderness and the Alpine Lakes Management Area to a management prescription which will maintain their roadless status. It also emphasizes the protection of natural scenery, fish and wildlife habitat, and other amenity values. Management of other resources would be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

The major changes in this alternative from the DEIS and the Supplement to the DEIS include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.

- Development and application of the Mather Memorial Parkway prescription (MP-1) which does not allow for scheduled timber harvest within the seen area of the Parkway corridor

Alternative F

This alternative emphasizes unroaded recreation, protection of natural scenery, fish and wildlife habitat, and other amenity values. It allocates approximately 80 percent of the currently roadless area outside of the existing wilderness and Alpine Lakes Management Area to roadless management prescriptions with heavy emphasis on non-motorized recreation. Management of other resources would be at economically and environmentally feasible levels consistent with the emphasis on amenity values.

The Forest was assisted in the development of this alternative by a coalition of environmental groups from throughout the State

The major changes in this alternative from the DEIS and the Supplement to the DEIS include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.

- Development and application of the Mather Memorial Parkway prescription (MP-1) which does not allow for scheduled timber harvest within the seen area of the Parkway corridor.

Alternative G

This alternative is an attempt to balance the land allocations between amenity values and commodity production emphasis. The goal was to intensify commodity production on the lands not allocated to roadless management. Of the currently roadless areas outside of existing Wilderness and the Alpine Lakes Management Area which are suitable for timber production, approximately half was allocated to roadless management with a heavy emphasis toward motorized recreation and the remainder was allocated to commod-

ity production. On the lands allocated to timber production, a trade-off was reached between maximizing present net value and maximizing timber production.

The Forest was assisted in the development of portions of this alternative by representatives of off-road vehicle users groups from throughout the State.

The major changes in this alternative from the DEIS and the Supplement to the DEIS include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.

Alternative H

This alternative was developed to portray the maximum timber producing capability of the Forest under the present land allocations of the existing management plans. This alternative has the same land allocations as Alternative A/NFMA. The major difference of this alternative compared to Alternative A/NFMA is that more intensive timber management will be practiced on the General Forest land allocation which will result in higher yields and higher annual sale quantities with a corresponding decrease in present net value.

The major changes in this alternative from the DEIS and the Supplement to the DEIS include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and "dedicating" old growth spotted owl habitat areas rather than "managing" old growth.
- Changes in classification on some of the recommended Wild and Scenic Rivers and deletion of some eligible segments with private land issues.

Alternative I

Alternative I is a departure from the base sale schedule established under Alternative C, the selected alternative. It has the same land allocation as Alternative C. The timber harvest schedule for Alternative C is based upon nondeclining flow, never exceeding long-term sustained yield. Alternative I has the same long-term sustained yield capacity as Alternative C but deviates from nondeclining flow. The level of timber harvest in the first decade approximates the average annual sell volume for fiscal years 1975 through 1984 under the existing Timber Management Plan. The level of timber harvest gradually declines in the second and third decades, equaling that of Alternative C in the fourth decade. This would allow local industry to phase into a lower level of timber harvest more gradually than in Alternative C. The effects on other resources could be greater in the early decades due to the accelerated rate of timber harvest under the departure

The major changes in this alternative from the DEIS and the Supplement to the DEIS include:

- Revision of the spotted owl network in response to the Supplement to the Regional Guide EIS and "dedicating" spotted owl habitat areas rather than "managing" them.
- Increase roadless areas from 267,610 acres to 298,115 acres.
- Development and application of the Mather Memorial Parkway prescription (MP-1) which does not allow for scheduled timber harvest within the Parkway corridor.
- An addition of two new allocations; EW-3 (Unroaded Wildlife) and RE-4 (Unroaded Harvest).
- Changes in the classification on some of the recommended Wild and Scenic Rivers and the addition of the Waptus River to those recommended for designation.

Alternative J

This alternative was developed by representatives of the timber industry after release of the Wenatchee DEIS. They referred to it during the public input process as the "Essential Alternative." The goal of this alternative is to maintain timber harvest and other commodity outputs at their highest levels, while providing as much amenity outputs as possible without dropping the ASQ below the level of the existing timber management plans.

Features of this alternative include:

- The highest acreage of GF land allocation of any of the alternatives with correspondingly lower roadless and scenic travel allocations
- No scenic travel retention allocations outside of the Alpine Lakes management area. I-90, Highway 2 (Stevens Pass) and Highway 97 (Swauk Pass) are in this management unit.
- Limited Partial Retention allocation on Mather Memorial Parkway, Entiat, Lake Wenatchee, and a part of the Chiwawa River road

The No Change Alternative (Alternative NC)

The No Change Alternative was developed in response to decisions made regarding appeal number 1588 brought by the Northwest Forest Resource Council on May 19, 1986. The appeal centered on a decision by Regional Forester James F. Torrence to "require inclusion of management requirements (MR's) in the Current Direction Alternative for each Forest Plan." In response to this, a No Change Alternative has been developed to represent the existing Timber Management plans and consequently does not comply with all provisions of the National Forest Management Act of 1976 (NFMA) and regulations (36 CFR 219) promulgated by the Secretary of Agriculture to implement NFMA.

Alternative NC displays the objectives, outputs, and effects of the Wenatchee National Forest's Timber Management (TM) Plans so that they can be compared with the other alternatives. However, since the development of the TM plans, new inventories, assumptions about resource interrelationships, and new methods for predicting timber growth and yields have been developed. Therefore, a reviewer should be aware that information provided for Alternative NC is frequently based on outdated inventories and yield tables and is not always comparable to information provided for the other alternatives.

COMPARISONS OF ALTERNATIVES

Table 3, "Comparison of Alternatives by Management Areas," and Table 4, "Comparison of Alternatives by Key Issue Areas," provide a comparison of the various alternatives considered in the FEIS.

Suitable Timber Lands (Acres) 3/	591,794	643,639	576,074	503,326	421,265	603,620	576,074	410,935	686,918	681,186

1/ Alternatives are ranked in order of decreasing present net value (except for NC which does not have a PNV computed) Resource outputs cannot be reasonably estimated for Alternative NC because the TM plans were based on different yield tables and resource relationships

2/ These production estimates were made using the mid-point of the decade Because of the life history of the fish, the effects of the different alternatives are not apparent in this short time frame

3/ Figures represent acres of suitable timber lands scheduled by the FORPLAN computer model for management

DISCUSSION OF ALTERNATIVES WITH HIGHER PRESENT NET VALUE

There are two alternatives: Alternative A/NFMA and Alternative D with a higher Present Net Value (PNV) than the selected alternative. Alternative A/NFMA has a PNV of 1,976 million dollars, 1,937 million dollars for Alternative D, and 1,910 million dollars for selected Alternative C.

In calculating present net value, a dollar value is assigned to various outputs. Some of these output values are market-determined and produce a revenue, such as timber. Other resource outputs use assigned values derived from research studies, such as recreation. However, present net value does not include a value for some resources that neither produce revenue nor have a basis from which to estimate a value as in the case of visual quality. Therefore, present net value cannot be the only criterion used in deciding which alternative to select. The criterion used was the maximization of net public benefit, which includes both the present net value of the priced outputs and the consideration of the nonpriced outputs.

In making my decision, I felt it was necessary to evaluate how opportunities could change by selecting alternatives with varying combinations of present net value and nonpriced outputs. This helped me understand the interactions occurring between resources in determining net public benefit. Table 4 displays each alternative along with an estimate of present net value arranged in order of decreasing present net value. In addition, Table 4 shows estimated outputs for selected priced and nonpriced resources which relate to the key issues used in deciding on the selected alternative.

Alternative A/NFMA

Alternative A/NFMA has the highest present net value of all the alternatives at 1,976 million dollars. This is 66 million dollars higher when compared to selected Alternative C.

This difference in PNV is due to the low recreation budget in Alternative A/NFMA, while recreation use and, therefore, benefits remain high. The low recreation budget, as compared to the selected alternative, will adversely affect the quality of the recreation experience for visitors to the Forest. This results in substantial reductions to net public benefits. It would also run counter to public comments which called for an increased emphasis on the recreation program.

Alternative A/NFMA has the fewest acres allocated to the management of key big-game habitat. Alternative A/NFMA has 17,151 acres allocated to key deer and elk range compared to 118,742 acres for the selected alternative. The public comments received on the DEIS stressed the importance of wildlife in the management of the Wenatchee.

Compared to the selected alternative, A/NFMA has fewer acres allocated to roadless management. In A/NFMA, 55 percent of the roadless areas will be roaded compared to 46 percent for the selected. Again, there were many public comments calling for protection of roadless areas.

Alternative A/NFMA lacked three management prescriptions that were included in the selected alternative. These were an Unroaded/Wildlife prescription, a special management prescription for the Mather Memorial Parkway, and an unroaded harvest prescription. The Unroaded/Wildlife prescription has been developed in response to public comments of having some wildlife areas remain unroaded. The Mather Memorial prescription recognizes the unique and special characteristics of the Mather Memorial Parkway. The unroaded harvest prescription protects the roadless character of an area while allowing some timber harvest.

Alternative C produces more wildlife habitat, a higher quality recreation experience, provides more roadless lands, and recognizes the unique character of areas like the Mather Memorial

Parkway. For these reasons, I think that Alternative C provides a more balanced resource program for the Wenatchee National Forest than Alternative A/NFMA, resulting in higher net public benefits.

Alternative D

Alternative D has the second highest present net value of all the alternatives at 1,937 million dollars. This is 27 million dollars more than selected Alternative C. This is due to the high acreage allocated to timber management coupled with the maximization of present net value. This alternative emphasizes the production of resources such as timber, range, forage, developed recreation, minerals, and other resources which have the potential to return revenue to the Federal Treasury and local counties.

Alternative D has the second fewest acres allocated to roadless management of the alternatives. Fully 59 percent of the roadless areas will be roaded compared to 46 percent for the selected alternative. Alternative D has 77,784 acres allocated to key deer and elk habitat compared to 118,742 acres for the selected alternative. In addition, the selected alternative provides for more old growth protection than Alternative D.

Alternative D results in about 33 percent of the Forest appearing in a modified visual environment over the 50-year planning horizon. This compares with about 20 percent for the selected alternative. Visual quality is a non-quantifiable public benefit that contributes significantly to net public benefits.

Alternative D does not have any rivers recommended for inclusion into the Wild and Scenic River System while the selected alternative recommends nine rivers for inclusion.

The selected alternative provides more wildlife habitat, more old growth, more roadless areas, a more natural appearing visual environment, and more key big-game habitat. It is for these reasons that I think that Alternative C provides higher net public benefits than Alternative D.

ENVIRONMENTALLY PREFERABLE ALTERNATIVE

Alternative E is the environmentally preferable alternative. The other alternatives that are environmentally preferable to C are F and G. These alternatives emphasize aesthetic values, fish and wildlife, roadless areas, and dispersed and unroaded recreation. Alternatives E and F emphasize unroaded non-motorized while Alternative G emphasizes unroaded motorized recreation.

I did not select Alternatives E, F, or G as they fail to fully recognize the demands imposed by local communities and the economic realities of our society. Another way of expressing this is that these alternatives do not provide an equitable balance between environmental considerations and economic realities.

For Alternatives E, F, and G, the associated change in employment compared to the 1982 base period is -520, -473, and -225 jobs respectively. The associated change in first decade income is -14.56, -13.30, and -6.54 million dollars respectively. These compare with a net change of +203 jobs and an increase of +5.14 million dollars for the selected alternative.

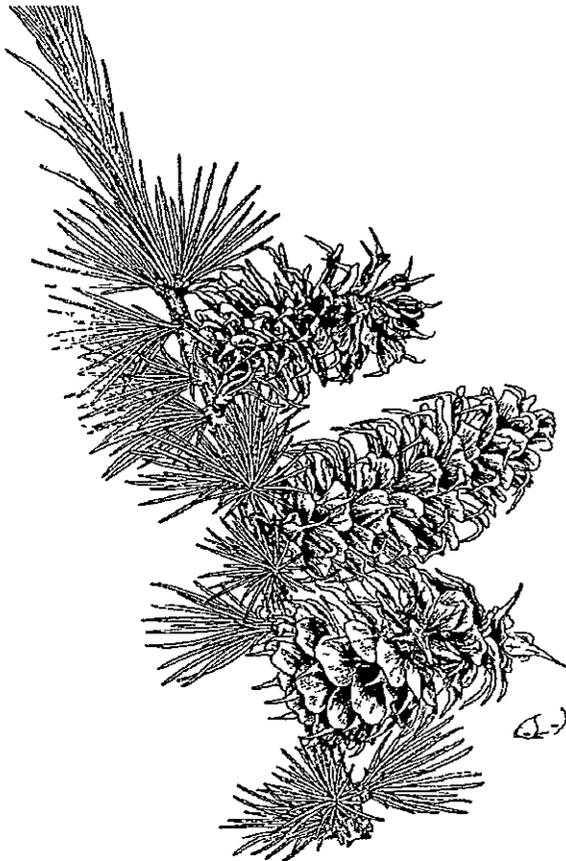

I believe that this reduction in jobs and local income is too high a cost for society in relation to the benefits of these alternatives. While the output of commodity resources from Alternative C is greater than the "environmentally preferable" alternatives, the specificity and detail in allocations, and subsequent mitigation through application of standards and guidelines, assures a high level of environmental protection and retention of future options.

In my judgment, Alternative C provides appropriate environmental safeguards at minimum direct economic cost. This alternative incorporates the perspective that the Forest Service is the trustee of the environment for succeeding generations. Alternative C provides for the proper and continued development of resources in a manner that maintains economic stability, and it retains local natural heritages, such as wildlife habitat, outdoor recreation opportunities, water quality, scenic quality, and open range. The selected alternative strikes the delicate balance between competing demands, which is required by law.

COMPATIBILITY WITH OTHER AGENCY GOALS AND PLANS

The goals of other Government agencies, which could be affected by management direction for the Wenatchee National Forest were considered early in the planning process and used to develop alternatives in the DEIS and FEIS. These agencies expressed their views during the comment period on how well the draft plan met their objectives. (See FEIS, Appendix K for a list of public agencies comments on the DEIS and Proposed Plan; and Appendix A for a list of agencies contacted early in the planning process.)

Alternative C has been carefully coordinated with goals and objectives of the State of Washington and their agencies, the Yakima Indian Nation, the Bureau of Land Management, and the Fish and Wildlife Service. There appear to be no major conflicts between implementation of this Plan and the goals and plans of other agencies. The U.S. Fish and Wildlife Service has proposed listing the northern spotted owl as threatened and is drafting a conservation strategy. Results of this listing process and subsequent changes to the Regional Guide, if any, will be used to make appropriate adjustments to the Plan.

ALTERNATIVE SELECTION

I select Alternative C because, in my judgment, it best maximizes net public benefits. Due to the controversial nature of the decisions, I am sharing with you, the reader, the factors I considered. I examined the possible alternatives and their associated environmental effects. I studied the public comment, including how well agencies felt the preferred alternative of the draft EIS met their plans. I compared the selected alternative to the "environmentally preferred alternatives" and to alternatives with higher present net values.

I believe that Alternative C reflects concern for the landscape and resource diversity of the Forest while providing for the social and economic needs of local and more distant communities. In my judgment, Alternative C provides appropriate environmental safeguards at an acceptable cost to society. All practicable means to avoid or minimize environmental harm from the selected alternative C have been adopted. This alternative provides for the needs of our society and conserves our natural resources for future generations.

IV. IMPLEMENTATION

SCHEDULES

The Forest Plan will be implemented through identification, selection, and scheduling of projects to meet the management goals and objectives provided by the Plan (see Plan Appendix A).

The schedule of proposed and possible projects for the first decade is contained in the appendices of the Forest Plan. Project schedules will be available for review at the Ranger District Offices and Supervisor's Office. Schedules of possible projects will routinely change as projects are implemented or are removed from the listings for other reasons and as new projects take their place. Adjustments to the schedule may be made based on results of monitoring, budgets, and unforeseen events.

The Forest Plan provides direction in the form of goals and objectives, standards and guidelines, monitoring requirements, and probable scheduling of management practices. It does not cover projects on specific sites except in a broad manner. Each proposed project will be subject to site-specific analysis and documentation in compliance with NEPA. Considerations revealed through this process may result in a decision not to proceed with the proposed project, even though the project may be permissible under the Forest Plan.

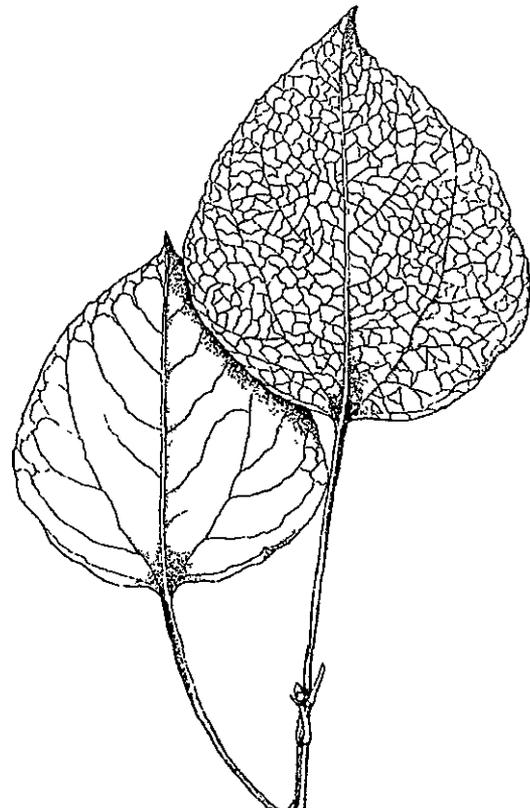

The Plan's scheduled projects are translated into multi-year program budget proposals. The schedule is used for requesting and allocating the funds needed to carry out the planned management direction. Upon approval of a final budget for the Forest, the annual work program will be updated and carried out.

The Forest work program will implement the management direction of the Forest Plan. Outputs and activities in individual years may be significantly different from those shown in Chapter IV of the Forest Plan, depending on final budgets, new information derived from updated inventories and monitoring, and any future amendments or revisions of the Forest Plan.

The Forest Plan supersedes or incorporates all previous land and resource management plans prepared for the Wenatchee National Forest. Upon implementation of the Plan, management activities will be made to comply with it. Appropriations or budgets may alter the schedule of activities. In addition, all permits, contracts, and other instruments for the use and occupancy of National Forest system lands and resource uses must be in conformance with the Forest Plan. Such documents will be revised where needed as soon as practicable, subject to valid existing rights. This updating will generally be done within three years.

All timber sales offered for sale after issuance of the Forest Plan will be in compliance with direction contained in the Plan. Timber sales now under contract will be administered under provisions of the existing contracts. Changes to existing timber sale contracts may be proposed on a case-by-case basis where overriding resource considerations are present.

The Forest Plan will be implemented 30 days after the Notice of Availability of the Forest Plan, EIS, and Record of Decision appears in the Federal Register.

AMENDMENT AND REVISION PROCESS

This Forest Plan may be changed either by an amendment or a revision. Such changes may come about as a result of the monitoring process or project analysis (see Forest Plan Chapter V). An amendment may become necessary as a result of different situations. They could include, for example:

Recommendations of the Interdisciplinary Team based on their review of monitoring results.

The determination that an existing or proposed permit, contract, cooperative agreement, or other instrument authorizing occupancy and use is not consistent with the Forest Plan, but should be approved, based on project level analysis.

Adjustment of management area boundaries or prescriptions.

Changes in proposed implementation schedules.

Changes necessitated by resolution of administrative appeals.

Changes needed to improve monitoring plans or information and assumptions used in the Plan.

Changes to correct minor errors or omissions, including clarification of text and tables.

Changes made necessary by altered physical, biological, social, or economic conditions.

Based on an analysis of the objectives, guidelines, and other aspects of the Forest Plan, the Forest Supervisor shall determine whether a proposed amendment would result in a significant change to the Plan. If the change is determined to be significant, the Forest Supervisor shall follow the same procedure as that required for development and approval of a plan. If the change is determined not to be significant, the Forest Supervisor

may implement the amendment after appropriate public notice and compliance with NEPA. The procedure is described by 36 CFR 219.10(e) and (f), 36 CFR 219.12(k), FSM 1922.51-52 and FSH 1909.12.

As Regional Forester, I will approve significant amendments and the Forest Supervisor "non-significant" amendments. The determination of significance must be documented in a decision notice and would be appealable under 36 CFR 217. A mailing list will be maintained to provide notification and invitation to comment on proposed amendments.

The amendment documentation will include as a minimum.

A statement of why the Forest Plan is being amended (some possible reasons are mentioned above).

The actual amendment showing exactly how it will look.

Rationale for the amendment.

A statement of significance related to FSM 1922.51. (This is the NFMA significance and relates to changes to the Forest Plan)

A statement regarding NEPA compliance (40 CFR 1500-1508, FSM 1950, and FSH 1909 15) regarding effects on the environment and how the effects disclosed in the Plan EIS may change as a result of the amendment

A statement of the appeal rights.

The NFMA requires revision of the Forest Plan at least every 15 years. However, it may be revised sooner if physical conditions or demands on the land and resources have changed sufficiently to affect overall goals or uses for the entire Forest. If a revision becomes necessary, the procedures described in 36 CFR 219.12 will be followed. The Chief must approve the scheduling of such a revision.

I believe the selected alternative maximizes net public benefits. The harvest level associated with the selected alternative represents our best interpretation of the current data. However, technical questions regarding yield tables and suitability continue to be raised. These concerns will be addressed as part of the normal plan implementation process. The Forest Plan is dynamic; as new information and technology is developed, whether through plan monitoring, new inventories or from efforts outside the Forest Service, appropriate changes will be made.

Some of the primary commentators have raised technical issues which they feel have not been resolved to their satisfaction. We will continue to analyze these issues, and if justified, will make appropriate changes during implementation. Accordingly, the Forest is conducting resource inventories that will produce new, detailed information to assist in these analyses. For example, we are continuing our cooperative soil survey program with the Soil Conservation Service and have implemented an accelerated stream survey program. We have also begun a coordinated timber resource inventory. This inventory will produce information that will increase our timber stratifications from the two current ones (see FEIS, Appendix B) to six or seven, allowing us to refine our tables and to locate specific species groups on the ground. To improve our working relationship with the interested public, we have invited them to become involved in this process. The data collection will be completed within three years and the detailed analysis will take approximately two more years.

The results of the new inventories and analyses will then be used to make any necessary adjustments to the Plan. Should intended outputs change significantly due to the new data, I will reconsider certain aspects of decisions I make in this Plan.

MONITORING AND EVALUATION

The Monitoring and Evaluation Program is the management control system for the Forest Plan. It will be used to provide information on the progress and results of implementation. One of the results of monitoring will be an assessment of the need for amending or revising the Plan. The monitoring and evaluation are discussed in more detail in Chapter V of the Plan.

Monitoring is intended to help keep the Forest Plan current and responsive to changes. Monitoring and evaluation each have a distinctly different purpose and scope. Monitoring consists of gathering data, observations, and information. During evaluation, the data and information are analyzed and interpreted. This process provides the information necessary to determine if conditions are within the bounds and intent of the Plan direction. Forest Plan monitoring does not replace or substitute for other Forest monitoring activities. Many activities are currently being monitored on the Forest to comply with administrative and legal responsibilities. (FSM - Admin Review Procedures).

Monitoring and evaluation will provide information to:

1. Compare planned versus applied management standards and guidelines to determine if objectives are achieved (36 CFR 219.12(k)).
2. Quantitatively compare planned versus actual outputs and services (36 CFR 219.12(k)(1)).
3. Measure effects of prescriptions, including significant changes in land productivity (36 CFR 219.12(k)(2)).
4. Determine planned costs versus actual costs associated with carrying out prescriptions (36 CFR 219.12(k)(3)).
5. Determine population trends of the management indicator species and relationship to habitat changes (36 CFR 219.19(a)(6)).
6. Evaluate effects of National Forest management on adjacent land, resources, and communities (36 CFR 219.7(f)).

7. Identify research needs to support or improve National Forest management (36 CFR 219.28)
8. Determine if lands are adequately restocked (36 CFR 219.12(k)(5)(i)).
9. Determine, at least every ten years, if lands identified as unsuitable for timber production have become suitable (36 CFR 219.12(k)(5)(ii)).
10. Determine whether maximum size limits for harvest areas should be continued (36 CFR 219.12(k)(5)(iii)).
11. Ensure that destructive insects and disease organisms do not increase to potentially damaging levels following management activities (36 CFR 219.12(k)(5)(iv)).

Results of the evaluation will lead to decisions of the following types:

1. Continue practice, no change necessary.
2. Refer the problem to the appropriate Forest officer for corrective action.
3. Modify the management practice through Plan amendments.
4. Modify land designation through Plan amendments.
5. Revise output schedules.
6. Revise unit output costs.
7. Revise the Plan.

MITIGATION

Mitigation is the key to sound land management. Mitigation measures are intended to minimize or eliminate potential conflicts or adverse effects of implementation. Mitigation measures have been developed through interdisciplinary efforts and incorporated into the Plans at different levels in several different ways:

1. The standards and guidelines and management area prescriptions in Chapter IV of the Plan are a fundamental and integral part of these measures, and as such they are a basic and essential part of the Plan.
2. The allocations play an important role in mitigation by the separation of incompatible uses, impacts, and conflicts
3. National Forest Management Act (NFMA) requirements were incorporated into the planning process and are reflected in the allocations and standards and guidelines.
4. "General Water Quality Best Management Practices" (USDA Forest Service, Pacific Northwest Region, November 1988) are incorporated by reference under requirements of Section 319 of the Clean Water Act
5. Mitigation measures are developed at the site specific project level of planning, and projects are "tiered" to other planning level measures above

All practical mitigation measures have been adopted and are included in the Forest Plan.

V. APPEAL RIGHTS

This decision may be appealed in accordance with the provisions of 36 CFR 217 by filing a written notice of appeal within 90 days of the date of this decision.

The appeal must be filed with the Reviewing Officer:

**F. Dale Robertson, Chief
USDA Forest Service
P.O. Box 96090
Washington, D.C. 20090-6090**

A copy must be sent simultaneously to the Deciding Officer:

**John F. Butrulle
Pacific Northwest Region
USDA Forest Service
319 S.W. Pine
P.O. Box 3623
Portland, OR 97208-3623**

The notice of appeal must include sufficient narrative evidence and argument to show why this decision should be changed or reversed (36 CFR 217.9).

Requests to stay the approval of this Land and Resource Management Plan shall not be granted (36 CFR 217.10(a)).

For a period not to exceed 20 days following the filing of a first level notice of appeal, the Reviewing Officer shall accept requests to intervene in the appeal from any interested or potentially affected person or organization (36 CFR 217.14(a)).

Decisions on site-specific projects are not made in this document.

The schedule of proposed and probable projects for the first decade is included in the appendices to the Plan. Final decisions on these proposed projects will be made after site-specific analysis and documentation in compliance with NEPA.

I encourage anyone concerned about the Plan or environmental impact statement to contact Sonny J. O'Neal, Forest Supervisor, in Wenatchee, Washington, phone number (509) 662-4335, before submitting an appeal. It may be possible to resolve the concern or misunderstanding in a less formal manner, but the 90 day appeal period will continue to run.
