**Geographic Range**

This BPS occurs in central Washington, Pasco Basin and similarly low-lying areas of the Columbia Plateau in Washington, and likely occurs in northern Oregon along the Columbia and Snake rivers. Additionally, the type may occur around Pleistocene lakes in the great basin.

**Biophysical Site Description**

This BPS occurs in the warmest and driest portions of the Columbia Plateau. Soils vary from silt-loam to sandy to lithic, although surface rock is uncommon in the lithic soil types. Average annual precipitation is around six to seven inches, falling primarily as winter rain.

**Vegetation Description**

Wyoming big sagebrush is the primary species. Spiny hopsage is often associated with the Wyoming big sagebrush and occasionally co-dominant or dominant. Basin big sagebrush is uncommon and limited to the most mesic sites.

Sandberg's bluegrass is the primary herbaceous species. Large bunchgrasses are generally absent except on sandy soils where needle-and-thread and Indian ricegrass occur. Forbs are relatively sparse and species richness relatively low compared to other big sagebrush BpSs.

**Disturbance Description**

Lightning fires are relatively rare due to a combination of a low number of strikes relative to surrounding areas and accompanying rain that often extinguishes starts. The BPS typically lacks the fine fuels needed to help fires start and spread readily. Nonetheless, fires did occur occasionally and could burn large areas.

---

**Fire Regime Groups are:**

- I: 0-35 year frequency, surface severity; II: 0-35 year frequency, replacement severity; III: 35-100+ year frequency, mixed severity; IV: 35-100+ year frequency, replacement severity; V: 200+ year frequency, replacement severity.
usually driven by wind.

Shrub die-offs have occurred in the late 20th C. in this type, but the causes are largely unknown. Whether similar die-offs were characteristic of the historical conditions is also unknown.

**Adjacency or Identification Concerns**
This type can easily be confused with the late-seral closed canopy stage of Inter-Mountain Basins Big Sagebrush Steppe (1125), particularly since fire exclusion, grazing, and other land use practices have resulted in a shift towards the late seral closed canopy stage in that BpS. However, from the ground level large bunchgrasses, particularly bluebunch wheatgrass, are generally absent from this BpS.

The Inter-Mountain Basins Big Sagebrush Steppe occurs adjacent and intergrades with this BpS. Inter-Mountain Basin Sparsely Vegetated Systems, particularly the Active and Stabilized Dune formation, co-occurs with this type.

**Native Uncharacteristic Conditions**
If more than 40% shrub cover is present, then another BpS is present.

**Scale Description**
This community occurs in the 1000s to 10,000s of acres, and disturbances could affect large areas of this.

**Issues/Problems**
Past over-grazing allowed invasive annual grasses, mostly cheatgrass, to establish within this BpS. Cheatgrass has fueled larger and more frequent fires than occurred historically and is resulting in a type conversion.

Grazing probably also contributed to an increasing density of large shrubs and reduction of perennial grasses.

Spiny hopsage has only rarely been observed to reproduce in central Washington over the last 50 years, basically since observations began.

The scope, scale, and purpose for any burning by Native Americans is not known.

**Comments**
Although the return interval suggests fire regime II, this was a mixed severity regime with relatively infrequent fire due to highly variable fine fuels. Many fires may have been small in size (under 100 ac) and not as ecologically significant as fires over 100 ac. These larger fires were more likely following wetter than average years with higher than average grass loadings.

Reviewers added a bit to extend the geographic range of the type, and to add rabbitbrush (Chrysothamnus) as a common shrub in the type, especially after disturbance. Large perennial bunchgrasses would also be common in addition to Sandberg’s bluegrass. Needle-and-thread, Bluebunch wheatgrass, basin wildrye would be the dominants. Model for MZ07 imported from MZ08 and MZ09.

**Description**
This class is dominated by herbs with canopy closure up to 10%. Typical species include Sandberg's bluegrass with needle-and-thread and Indian ricegrass on sandy soils and perennial forbs such as Carey's balsamroot and native annual forbs. Succession to Class B after 15yrs.

**Description**
Small, scattered sagebrush and spiny hopsage are now present although canopy cover from shrubs is generally <10%. Sandberg's bluegrass remains the dominant grass species on most soils. Forbs are well established and essentially mature with cover of <10% Total vegetation cover is generally 25% or less. Biological soil crusts are reforming but large amounts of bare ground remain. Succession to Class C after 20yrs. Mixed and replacement fires.

</table>

**Description**
Sagebrush and spiny hopsage are approaching maximum size with some additional regeneration present. Shrub cover is higher, but still generally <20%. The mix of grass and forb species generally remains unchanged with a canopy cover of about 20% or less. Biological soil crusts are now well developed although areas of bare soil remain. Succession to Class D after 45yrs.

**Fire Intervals (FI)**:

Fire interval is expressed in years for each fire severity class and for all types of fire combined (All Fires). Average FI is central tendency modeled. Minimum and maximum show the relative range of fire intervals, if known. Probability is the inverse of fire interval in years and is used in reference condition modeling. Percent of all fires is the percent of all fires in that severity class.
