INTRODUCTION

Armillaria root disease is caused by a complex of species that infect many conifer and hardwood tree hosts (Fig. 1 and 2). Variability in host range, aggressiveness, and site preferences may be due to the occurrence or co-occurrence of different *Armillaria* species.

This disease is associated with various forest tree declines worldwide and can play a role in tree mortality often attributed solely to insects. *Armillaria* is a major forest pest in the states neighboring Wyoming, yet little is known about its occurrence or distribution within this state. Recent Forest Health Monitoring detection surveys documented widespread tree decline and mortality in Wyoming, which motivated this study. This is the first statewide evaluation monitoring study of *Armillaria* root disease in Wyoming.

Knowing distributions of the different species, understanding differences in host ranges and aggressiveness, and determining optimal growth conditions can help determine disease management measures.

OBJECTIVES

- 1 Examine the geographic distribution of different *Armillaria* species in Wyoming.
- 2 Characterize relationships among hosts, site conditions, and *Armillaria* species.

MATERIALS & METHODS

Sample locations include federal, state, and tribal forested lands throughout Wyoming. Selections were made, site-unseen, based on ownership, vegetation type, and accessibility (Fig 3). All major forest cover types will be included.

Plots are 15 m square. Plot variables recorded include: slope; aspect; forest cover type; organic matter thickness; frequency of rhizomorphs in the soil; number of stumps, snags, and logs per plot; and tree species and diameter at breast height (DBH) for all live trees per plot. Soil samples are being analyzed for organic matter content, pH, and texture.

Host tree variables recorded include: species, DBH, host condition (living or dead), crown position, percentage live crown, and associated stress/mortality agents.

Armillaria species are being determined in the laboratory from samples collected from the hosts (Fig 4).

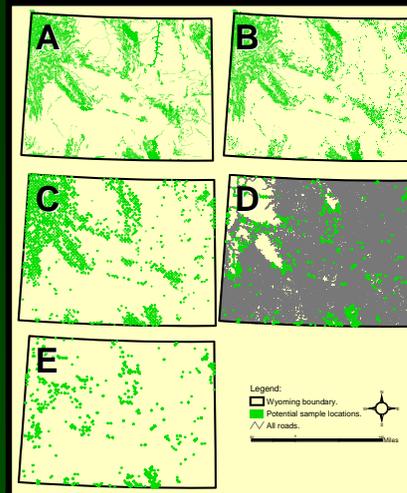

Fig 3. Selection of proposed sample locations. (A) Forest cover in Wyoming; (B) forest cover on federal, state, and tribal lands; (C) a grid was used to systematically select locations; (D) accessibility was considered; (E) final proposed sample locations.

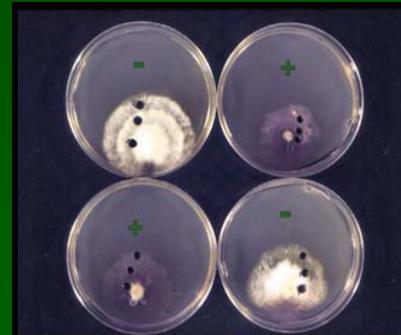

Fig. 4. Species identification of unknown diploid isolates using haploid tester isolates in mating tests. The upper inoculum is an identified haploid tester strain and the lower inoculum is the isolate to be identified in each plate.

RESULTS

We completed 220 plots in 12 different forest cover types in 2004 and 2005 (Fig. 5) and expect to have 300 total plots by the end of 2006. To date, *Armillaria* has been found at 49 locations. Sixty-nine isolates were collected, and these are being identified to species. Three *Armillaria* species have been identified so far, with *A. sinapina* being the most common, followed by *A. gallica* and *A. ostoyae*.

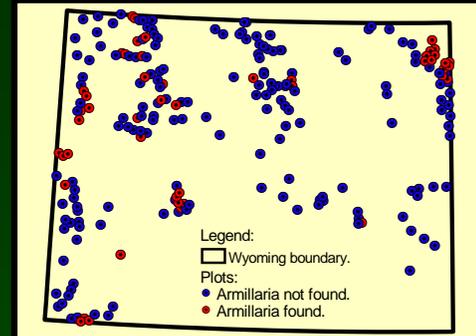

Fig. 5. Sample plots completed. Blue dots show where *Armillaria* was not found, and red dots show where *Armillaria* was found.

FUTURE RESULTS / PRODUCTS

- 1 New data about an important forest health issue.
- 2 Information regarding *Armillaria* species in Wyoming and their associated hosts and forest cover types.
- 3 Descriptions of associated soil and stand ecology of different *Armillaria* species.
- 4 Coarse-scale distribution and hazard maps.
- 5 Spatial distribution of *Armillaria* compared with Forest Health Monitoring detection survey data, precipitation, and climate data.
- 6 Baseline information for future monitoring and surveys of this important disease.
